68546       }
68547       /*
68548        *  This comparison routine can be used with tdelete()
68549        *  when explicitly deleting a root node, as no comparison
68550        *  is necessary.
```

```
 */
int
delete_root(const void *node1, const void *node2)
{
    return 0;
}

/*
 *  This routine prints out a node, the second time
 *  twalk encounters it or if it is a leaf.
 */
void
print_node(const void *ptr, VISIT order, int level)
{
    const struct element *p = *(const struct element **) ptr;

    if (order == postorder || order == leaf)  {
        (void) printf("string = %s,  count = %d\n",
            p->string, p->count);
    }
}
```

APPLICATION USAGE

The *root* argument to *twalk*( ) is one level of indirection less than the *rootp* arguments to *tdelete*( ) and *tsearch*( ).

There are two nomenclatures used to refer to the order in which tree nodes are visited. The *twalk*( ) function uses **preorder**, **postorder**, and **endorder** to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternative nomenclature uses **preorder**, **inorder**, and **postorder** to refer to the same visits, which could result in some confusion over the meaning of **postorder**.

Since the return value of *tdelete*( ) is an unspecified non-null pointer in the case that the root of the tree has been deleted, applications should only use the return value of *tdelete*( ) as indication of success or failure and should not assume it can be dereferenced. Some implementations in this case will return a pointer to the new root of the tree (or to an empty tree if the deleted root node was the only node in the tree); other implementations return arbitrary non-null pointers.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The last paragraph of the DESCRIPTION was included as an APPLICATION USAGE note in previous issues.

68595 **Issue 6**

68596 The normative text is updated to avoid use of the term ``must'' for application requirements.

68597 The **restrict** keyword is added to the *tdelete*( ) prototype for alignment with the
68598 ISO/IEC 9899: 1999 standard.

68599 **Issue 7**

68600 Austin Group Interpretation 1003.1-2001 #149 is applied, clarifying concurrent use of the tree in
68601 another thread.

68602 Austin Group Interpretation 1003.1-2001 #151 is applied, clarifying behavior for *tdelete*( ) when
68603 the deleted node is the root node.

68604 Austin Group Interpretation 1003.1-2001 #153 is applied.

68605 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0366 [551] is applied.

68606 **NAME**

68607 telldir — current location of a named directory stream

68608 **SYNOPSIS**

68609 XSI
```
#include <dirent.h>

long telldir(DIR *dirp);
```

68610

68611 **DESCRIPTION**

68612 The *telldir*( ) function shall obtain the current location associated with the directory stream
68613 specified by *dirp*.

68614 If the most recent operation on the directory stream was a *seekdir*( ), the directory position
68615 returned from the *telldir*( ) shall be the same as that supplied as a *loc* argument for *seekdir*( ).

68616 **RETURN VALUE**

68617 Upon successful completion, *telldir*( ) shall return the current location of the specified directory
68618 stream.

68619 **ERRORS**

68620 No errors are defined.

68621 **EXAMPLES**

68622 None.

68623 **APPLICATION USAGE**

68624 None.

68625 **RATIONALE**

68626 None.

68627 **FUTURE DIRECTIONS**

68632 **CHANGE HISTORY**

68633 First released in Issue 2.

68634 **NAME**

68635 tempnam — create a name for a temporary file

68636 **SYNOPSIS**

68637 OB XSI
```
#include <stdio.h>

char *tempnam(const char *dir, const char *pfx);
```
68638

68639 **DESCRIPTION**

68640 The *tempnam*( ) function shall generate a pathname that may be used for a temporary file.

68641 The *tempnam*( ) function allows the user to control the choice of a directory. The *dir* argument
68642 points to the name of the directory in which the file is to be created. If *dir* is a null pointer or
68643 points to a string which is not a name for an appropriate directory, the path prefix defined as
68644 P_tmpdir in the **<stdio.h>** header shall be used. If that directory is not accessible, an
68645 implementation-defined directory may be used.

68646 Many applications prefer their temporary files to have certain initial letter sequences in their
68647 names. The *pfx* argument should be used for this. This argument may be a null pointer or point
68648 to a string of up to five bytes to be used as the beginning of the filename.

68649 Some implementations of *tempnam*( ) may use *tmpnam*( ) internally. On such implementations, if
68650 called more than {TMP_MAX} times in a single process, the behavior is implementation-defined.

68651 **RETURN VALUE**

68652 Upon successful completion, *tempnam*( ) shall allocate space for a string, put the generated
68653 pathname in that space, and return a pointer to it. The pointer shall be suitable for use in a
68654 subsequent call to *free*( ). Otherwise, it shall return a null pointer and set *errno* to indicate the
68655 error.

68656 **ERRORS**

68657 The *tempnam*( ) function shall fail if:

68658 [ENOMEM] Insufficient storage space is available.

68659 **EXAMPLES**

68660 **Generating a Pathname**

68661 The following example generates a pathname for a temporary file in directory **/tmp**, with the
68662 prefix *file*. After the pathname has been created, the call to *free*( ) deallocates the space used to
68663 store the pathname.

```
68664 #include <stdio.h>
68665 #include <stdlib.h>
68666 ...
68667 const char *directory = "/tmp";
68668 const char *fileprefix = "file";
68669 char *file;

68670 file = tempnam(directory, fileprefix);
68671 free(file);
```

68672 **APPLICATION USAGE**

68673 This function only creates pathnames. It is the application's responsibility to create and remove
68674 the files. Between the time a pathname is created and the file is opened, it is possible for some
68675 other process to create a file with the same name. Applications may find *tmpfile*( ) more useful.

68676 Applications should use the *tmpfile*( ), *mkdtemp*( ), or *mkstemp*( ) functions instead of the

obsolescent *tempnam*( ) function.

RATIONALE

None.

FUTURE DIRECTIONS

The *tempnam*( ) function may be removed in a future version.

SEE ALSO

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The last paragraph of the DESCRIPTION was included as an APPLICATION USAGE note in previous issues.

Issue 7

The *tempnam*( ) function is marked obsolescent.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0657 [291], XSH/TC1-2008/0658 [137], and XSH/TC1-2008/0659 [137] are applied.

68694 **NAME**

68695 tfind — search binary search tree

68696 **SYNOPSIS**

68697 XSI
```
#include <search.h>

void *tfind(const void *key, void *const *rootp,
    int (*compar)(const void *, const void *));
```

68700 **DESCRIPTION**

68701 Refer to *tdelete( )*.

68702 **NAME**

68703 tgamma, tgammaf, tgammal ‡'compute gamma( ) function

68704 **SYNOPSIS**

68705 `#include <math.h>`

68706 `double tgamma(double x);`
68707 `float tgammaf(float x);`
68708 `long double tgammal(long double x);`

68709 **DESCRIPTION**

68710 CX The functionality described on this reference page is aligned with the ISO C standard. Any
68711 conflict between the requirements described here and the ISO C standard is unintentional. This
68712 volume of POSIX.1-2017 defers to the ISO C standard.

68713 These functions shall compute $\Gamma(x)$ where $\Gamma(x)$ is defined as $\int_0^\infty e^{-t}t^{x-1}dt$.

68714 An application wishing to check for error situations should set *errno* to zero and call
68715 *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or
68716 *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-
68717 zero, an error has occurred.

68718 **RETURN VALUE**

68719 Upon successful completion, these functions shall return the gamma of x.

68720 CX If x is a negative integer, a domain error may occur and either a NaN (if supported) or an
68721 MX implementation-defined value shall be returned. On systems that support the IEC 60559
68722 Floating-Point option, a domain error shall occur and a NaN shall be returned.

68723 If x is ±0, *tgamma*( ), *tgammaf*( ), and *tgammal*( ) shall return ±HUGE_VAL, ±HUGE_VALF, and
68724 MX ±HUGE_VALL, respectively. On systems that support the IEC 60559 Floating-Point option, a
68725 CX pole error shall occur; otherwise, a pole error may occur.

68726 If the correct value would cause overflow, a range error shall occur and *tgamma*( ), *tgammaf*( ),
68727 and *tgammal*( ) shall return ±HUGE_VAL, ±HUGE_VALF, or ±HUGE_VALL, respectively, with
68728 the same sign as the correct value of the function.

68729 MXX If the correct value would cause underflow, and is not representable, a range error may occur,
68730 MXX and *tgamma*( ), *tgammaf*( ), and *tgammal*( ) shall return 0.0, or (if IEC 60559 Floating-Point is not
68731 supported) an implementation-defined value no greater in magnitude than DBL_MIN,
68732 FLT_MIN, and LDBL_MIN, respectively.

68733 MXX If the correct value would cause underflow, and is representable, a range error may occur and
68734 the correct value shall be returned.

68735 If x is subnormal and $1/x$ is representable, $1/x$ should be returned.

68736 MX If x is NaN, a NaN shall be returned.

68737 If x is +Inf, x shall be returned.

68738 If x is –Inf, a domain error shall occur, and a NaN shall be returned.

68739 **ERRORS**

68740 These functions shall fail if:

68741 MX Domain Error The value of x is a negative integer, or x is –Inf.

68742 If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero,
68743 then *errno* shall be set to [EDOM]. If the integer expression (*math_errhandling*

& MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

MX Pole Error — The value of *x* is zero.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

Range Error — The value overflows.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

Domain Error — The value of *x* is a negative integer.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

Pole Error — The value of *x* is zero.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

Range Error — The result underflows.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (*math_errhandling* & MATH_ERRNO) and (*math_errhandling* & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

This function is named *tgamma*( ) in order to avoid conflicts with the historical *gamma*( ) and *lgamma*( ) functions.

FUTURE DIRECTIONS

It is possible that the error response for a negative integer argument may be changed to a pole error and a return value of ±Inf.

68786 **CHANGE HISTORY**

68787 First released in Issue 6. Derived from the ISO/IEC 9899: 1999 standard.

68788 IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/65 is applied, correcting the third
68789 paragraph in the RETURN VALUE section.

68790 **Issue 7**

68791 ISO/IEC 9899: 1999 standard, Technical Corrigendum 2 #52 (SD5-XSH-ERN-85) is applied.

68792 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0660 [68], XSH/TC1-2008/0661 [320],
68793 and XSH/TC1-2008/0662 [68] are applied.

68794 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0367 [604] and XSH/TC2-2008/0368
68795 [630] are applied.

68796 **NAME**

68797 time ‡'get time

68798 **SYNOPSIS**

68799
```
#include <time.h>
```

68800
```
time_t time(time_t *tloc);
```

68801 **DESCRIPTION**

68802 CX The functionality described on this reference page is aligned with the ISO C standard. Any
68803 conflict between the requirements described here and the ISO C standard is unintentional. This
68804 volume of POSIX.1-2017 defers to the ISO C standard.

68805 CX The *time*( ) function shall return the value of time in seconds since the Epoch.

68806 The *tloc* argument points to an area where the return value is also stored. If *tloc* is a null pointer,
68807 no value is stored.

68808 **RETURN VALUE**

68809 Upon successful completion, *time*( ) shall return the value of time. Otherwise, (**time_t**)−1 shall be
68810 returned.

68811 **ERRORS**

68812 The *time*( ) function may fail if:

68813 CX [EOVERFLOW] The number of seconds since the Epoch will not fit in an object of type **time_t**.

68814 **EXAMPLES**

68815 **Getting the Current Time**

68816 The following example uses the *time*( ) function to calculate the time elapsed, in seconds, since
68817 the Epoch, *localtime*( ) to convert that value to a broken-down time, and *asctime*( ) to convert the
68818 broken-down time values into a printable string.

68819
```
#include <stdio.h>
#include <time.h>
```

68821
```
int main(void)
{
time_t result;
```

68824
```
    result = time(NULL);
    printf("%s%ju secs since the Epoch\n",
        asctime(localtime(&result)),
            (uintmax_t)result);
    return(0);
}
```

68830 This example writes the current time to *stdout* in a form like this:

68831
```
Wed Jun 26 10:32:15 1996
835810335 secs since the Epoch
```

68833 **Timing an Event**

68834 The following example gets the current time, prints it out in the user's format, and prints the
68835 number of minutes to an event being timed.

```
68836 #include <time.h>
68837 #include <stdio.h>
68838 ...
68839 time_t now;
68840 int minutes_to_event;
68841 ...
68842 time(&now);
68843 minutes_to_event = ...;
68844 printf("The time is ");
68845 puts(asctime(localtime(&now)));
68846 printf("There are %d minutes to the event.\n",
68847     minutes_to_event);
68848 ...
```

68849 **APPLICATION USAGE**

68850 None.

68851 **RATIONALE**

68852 The *time*( ) function returns a value in seconds while *clock_gettime*( ) and *gettimeofday*( ) return a
68853 **struct timespec** (seconds and nanoseconds) and **struct timeval** (seconds and microseconds),
68854 respectively, and are therefore capable of returning more precise times. The *times*( ) function is
68855 also capable of more precision than *time*( ) as it returns a value in clock ticks, although it returns
68856 the elapsed time since an arbitrary point such as system boot time, not since the epoch.

68857 Implementations in which **time_t** is a 32-bit signed integer (many historical implementations)
68858 fail in the year 2038. POSIX.1-2017 does not address this problem. However, the use of the **time_t**
68859 type is mandated in order to ease the eventual fix.

68860 On some systems the *time*( ) function is implemented using a system call that does not return an
68861 error condition in addition to the return value. On these systems it is impossible to differentiate
68862 between valid and invalid return values and hence overflow conditions cannot be reliably
68863 detected.

68864 The use of the **<time.h>** header instead of **<sys/types.h>** allows compatibility with the ISO C
68865 standard.

68866 Many historical implementations (including Version 7) and the 1984 /usr/group standard use
68867 **long** instead of **time_t**. This volume of POSIX.1-2017 uses the latter type in order to agree with
68868 the ISO C standard.

68869 **FUTURE DIRECTIONS**

68870 In a future version of this volume of POSIX.1-2017, **time_t** is likely to be required to be capable
68871 of representing times far in the future. Whether this will be mandated as a 64-bit type or a
68872 requirement that a specific date in the future be representable (for example, 10000 AD) is not yet
68873 determined. Systems purchased after the approval of this volume of POSIX.1-2017 should be
68874 evaluated to determine whether their lifetime will extend past 2038.

68887 applied.

NAME

timer_create — create a per-process timer

SYNOPSIS

CX
```
#include <signal.h>
#include <time.h>

int timer_create(clockid_t clockid, struct sigevent *restrict evp,
    timer_t *restrict timerid);
```

DESCRIPTION

The *timer_create*( ) function shall create a per-process timer using the specified clock, *clock_id*, as the timing base. The *timer_create*( ) function shall return, in the location referenced by *timerid*, a timer ID of type **timer_t** used to identify the timer in timer requests. This timer ID shall be unique within the calling process until the timer is deleted. The particular clock, *clock_id*, is defined in **<time.h>**. The timer whose ID is returned shall be in a disarmed state upon return from *timer_create*( ).

The *evp* argument, if non-NULL, points to a **sigevent** structure. This structure, allocated by the application, defines the asynchronous notification to occur as specified in Section 2.4.1 (on page 488) when the timer expires. If the *evp* argument is NULL, the effect is as if the *evp* argument pointed to a **sigevent** structure with the *sigev_notify* member having the value SIGEV_SIGNAL, the *sigev_signo* having a default signal number, and the *sigev_value* member having the value of the timer ID.

Each implementation shall define a set of clocks that can be used as timing bases for per-process
MON timers. All implementations shall support a *clock_id* of CLOCK_REALTIME. If the Monotonic Clock option is supported, implementations shall support a *clock_id* of CLOCK_MONOTONIC.

Per-process timers shall not be inherited by a child process across a *fork*( ) and shall be disarmed and deleted by an *exec*.

CPT If _POSIX_CPUTIME is defined, implementations shall support *clock_id* values representing the CPU-time clock of the calling process.

TCT If _POSIX_THREAD_CPUTIME is defined, implementations shall support *clock_id* values representing the CPU-time clock of the calling thread.

CPT | TCT It is implementation-defined whether a *timer_create*( ) function will succeed if the value defined by *clock_id* corresponds to the CPU-time clock of a process or thread different from the process or thread invoking the function.

TSA If *evp* ~~->~~*sigev_sigev_notify* is SIGEV_THREAD and *sev* ~~->~~*sigev_notify_attributes* is not NULL, if the attribute pointed to by *sev* ~~->~~*sigev_notify_attributes* has a thread stack address specified by a call to *pthread_attr_setstack*( ), the results are unspecified if the signal is generated more than once.

RETURN VALUE

If the call succeeds, *timer_create*( ) shall return zero and update the location referenced by *timerid* to a **timer_t**, which can be passed to the per-process timer calls. If an error occurs, the function shall return a value of −1 and set *errno* to indicate the error. The value of *timerid* is undefined if an error occurs.

ERRORS

The *timer_create*( ) function shall fail if:

[EAGAIN] The system lacks sufficient signal queuing resources to honor the request.

[EAGAIN] The calling process has already created all of the timers it is allowed by this implementation.

[EINVAL] The specified clock ID is not defined.

CPT | TCT [ENOTSUP] The implementation does not support the creation of a timer attached to the CPU-time clock that is specified by *clock_id* and associated with a process or thread different from the process or thread invoking *timer_create*( ).

EXAMPLES

None.

APPLICATION USAGE

If a timer is created which has *evp*→*sigev_sigev_notify* set to SIGEV_THREAD and the attribute pointed to by *evp*→*sigev_notify_attributes* has a thread stack address specified by a call to *pthread_attr_setstack*( ), the memory dedicated as a thread stack cannot be recovered. The reason for this is that the threads created in response to a timer expiration are created detached, or in an unspecified way if the thread attribute's *detachstate* is PTHREAD_CREATE_JOINABLE. In neither case is it valid to call *pthread_join*( ), which makes it impossible to determine the lifetime of the created thread which thus means the stack memory cannot be reused.

RATIONALE

Periodic Timer Overrun and Resource Allocation

The specified timer facilities may deliver realtime signals (that is, queued signals) on implementations that support this option. Since realtime applications cannot afford to lose notifications of asynchronous events, like timer expirations or asynchronous I/O completions, it must be possible to ensure that sufficient resources exist to deliver the signal when the event occurs. In general, this is not a difficulty because there is a one-to-one correspondence between a request and a subsequent signal generation. If the request cannot allocate the signal delivery resources, it can fail the call with an [EAGAIN] error.

Periodic timers are a special case. A single request can generate an unspecified number of signals. This is not a problem if the requesting process can service the signals as fast as they are generated, thus making the signal delivery resources available for delivery of subsequent periodic timer expiration signals. But, in general, this cannot be assured ‡for processing of periodic timer signals may ``overrun''; that is, subsequent periodic timer expirations may occur before the currently pending signal has been delivered.

Also, for signals, according to the POSIX.1-1990 standard, if subsequent occurrences of a pending signal are generated, it is implementation-defined whether a signal is delivered for each occurrence. This is not adequate for some realtime applications. So a mechanism is required to allow applications to detect how many timer expirations were delayed without requiring an indefinite amount of system resources to store the delayed expirations.

The specified facilities provide for an overrun count. The overrun count is defined as the number of extra timer expirations that occurred between the time a timer expiration signal is generated and the time the signal is delivered. The signal-catching function, if it is concerned with overruns, can retrieve this count on entry. With this method, a periodic timer only needs one ``signal queuing resource'' that can be allocated at the time of the *timer_create*( ) function call.

A function is defined to retrieve the overrun count so that an application need not allocate static storage to contain the count, and an implementation need not update this storage asynchronously on timer expirations. But, for some high-frequency periodic applications, the overhead of an additional system call on each timer expiration may be prohibitive. The functions, as defined, permit an implementation to maintain the overrun count in user space,

associated with the *timerid*. The *timer_getoverrun*( ) function can then be implemented as a macro that uses the *timerid* argument (which may just be a pointer to a user space structure containing the counter) to locate the overrun count with no system call overhead. Other implementations, less concerned with this class of applications, can avoid the asynchronous update of user space by maintaining the count in a system structure at the cost of the extra system call to obtain it.

Timer Expiration Signal Parameters

The Realtime Signals Extension option supports an application-specific datum that is delivered to the extended signal handler. This value is explicitly specified by the application, along with the signal number to be delivered, in a **sigevent** structure. The type of the application-defined value can be either an integer constant or a pointer. This explicit specification of the value, as opposed to always sending the timer ID, was selected based on existing practice.

It is common practice for realtime applications (on non-POSIX systems or realtime extended POSIX systems) to use the parameters of event handlers as the case label of a switch statement or as a pointer to an application-defined data structure. Since *timer_id*s are dynamically allocated by the *timer_create*( ) function, they can be used for neither of these functions without additional application overhead in the signal handler; for example, to search an array of saved timer IDs to associate the ID with a constant or application data structure.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *timer_create*( ) function is marked as part of the Timers option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

CPU-time clocks are added for alignment with IEEE Std 1003.1d-1999.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by adding the requirement for the CLOCK_MONOTONIC clock under the Monotonic Clock option.

The **restrict** keyword is added to the *timer_create*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/138 is applied, updating the DESCRIPTION and APPLICATION USAGE sections to describe the case when a timer is created with the notification method set to SIGEV_THREAD.

Issue 7

The *timer_create*( ) function is moved from the Timers option to the Base.

NAME

timer_delete — delete a per-process timer

SYNOPSIS

CX
```
#include <time.h>

int timer_delete(timer_t timerid);
```

DESCRIPTION

The *timer_delete*( ) function deletes the specified timer, *timerid*, previously created by the *timer_create*( ) function. If the timer is armed when *timer_delete*( ) is called, the behavior shall be as if the timer is automatically disarmed before removal. The disposition of pending signals for the deleted timer is unspecified.

The behavior is undefined if the value specified by the *timerid* argument to *timer_delete*( ) does not correspond to a timer ID returned by *timer_create*( ) but not yet deleted by *timer_delete*( ).

RETURN VALUE

If successful, the *timer_delete*( ) function shall return a value of zero. Otherwise, the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

If an implementation detects that the value specified by the *timerid* argument to *timer_delete*( ) does not correspond to a timer ID returned by *timer_create*( ) but not yet deleted by *timer_delete*( ), it is recommended that the function should fail and report an [EINVAL] error.

FUTURE DIRECTIONS

None.

SEE ALSO

timer_create( )

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/139 is applied, updating the ERRORS section so that the [EINVAL] error becomes optional.

Issue 7

The *timer_delete*( ) function is moved from the Timers option to the Base.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0369 [659] is applied.

NAME

timer_getoverrun, timer_gettime, timer_settime — per-process timers

SYNOPSIS

CX
```
#include <time.h>

int timer_getoverrun(timer_t timerid);
int timer_gettime(timer_t timerid, struct itimerspec *value);
int timer_settime(timer_t timerid, int flags,
    const struct itimerspec *restrict value,
    struct itimerspec *restrict ovalue);
```

DESCRIPTION

The *timer_gettime*( ) function shall store the amount of time until the specified timer, *timerid*, expires and the reload value of the timer into the space pointed to by the *value* argument. The *it_value* member of this structure shall contain the amount of time before the timer expires, or zero if the timer is disarmed. This value is returned as the interval until timer expiration, even if the timer was armed with absolute time. The *it_interval* member of *value* shall contain the reload value last set by *timer_settime*( ).

The *timer_settime*( ) function shall set the time until the next expiration of the timer specified by *timerid* from the *it_value* member of the *value* argument and arm the timer if the *it_value* member of *value* is non-zero. If the specified timer was already armed when *timer_settime*( ) is called, this call shall reset the time until next expiration to the *value* specified. If the *it_value* member of *value* is zero, the timer shall be disarmed. The effect of disarming or resetting a timer with pending expiration notifications is unspecified.

If the flag TIMER_ABSTIME is not set in the argument *flags*, *timer_settime*( ) shall behave as if the time until next expiration is set to be equal to the interval specified by the *it_value* member of *value*. That is, the timer shall expire in *it_value* nanoseconds from when the call is made. If the flag TIMER_ABSTIME is set in the argument *flags*, *timer_settime*( ) shall behave as if the time until next expiration is set to be equal to the difference between the absolute time specified by the *it_value* member of *value* and the current value of the clock associated with *timerid*. That is, the timer shall expire when the clock reaches the value specified by the *it_value* member of *value*. If the specified time has already passed, the function shall succeed and the expiration notification shall be made.

The reload value of the timer shall be set to the value specified by the *it_interval* member of *value*. When a timer is armed with a non-zero *it_interval*, a periodic (or repetitive) timer is specified.

Time values that are between two consecutive non-negative integer multiples of the resolution of the specified timer shall be rounded up to the larger multiple of the resolution. Quantization error shall not cause the timer to expire earlier than the rounded time value.

If the argument *ovalue* is not NULL, the *timer_settime*( ) function shall store, in the location referenced by *ovalue*, a value representing the previous amount of time before the timer would have expired, or zero if the timer was disarmed, together with the previous timer reload value. Timers shall not expire before their scheduled time.

Only a single signal shall be queued to the process for a given timer at any point in time. When a timer for which a signal is still pending expires, no signal shall be queued, and a timer overrun shall occur. When a timer expiration signal is delivered to or accepted by a process, the *timer_getoverrun*( ) function shall return the timer expiration overrun count for the specified timer. The overrun count returned contains the number of extra timer expirations that occurred between the time the signal was generated (queued) and when it was delivered or accepted, up

to but not including an implementation-defined maximum of {DELAYTIMER_MAX}. If the number of such extra expirations is greater than or equal to {DELAYTIMER_MAX}, then the overrun count shall be set to {DELAYTIMER_MAX}. The value returned by *timer_getoverrun*( ) shall apply to the most recent expiration signal delivery or acceptance for the timer. If no expiration signal has been delivered for the timer, the return value of *timer_getoverrun*( ) is unspecified.

The behavior is undefined if the value specified by the *timerid* argument to *timer_getoverrun*( ), *timer_gettime*( ), or *timer_settime*( ) does not correspond to a timer ID returned by *timer_create*( ) but not yet deleted by *timer_delete*( ).

RETURN VALUE

If the *timer_getoverrun*( ) function succeeds, it shall return the timer expiration overrun count as explained above.

If the *timer_gettime*( ) or *timer_settime*( ) functions succeed, a value of 0 shall be returned.

If an error occurs for any of these functions, the value −1 shall be returned, and *errno* set to indicate the error.

ERRORS

The *timer_settime*( ) function shall fail if:

[EINVAL] A *value* structure specified a nanosecond value less than zero or greater than or equal to 1 000 million, and the *it_value* member of that structure did not specify zero seconds and nanoseconds.

The *timer_settime*( ) function may fail if:

[EINVAL] The *it_interval* member of *value* is not zero and the timer was created with notification by creation of a new thread (*sigev_sigev_notify* was SIGEV_THREAD) and a fixed stack address has been set in the thread attribute pointed to by *sigev_notify_attributes*.

EXAMPLES

None.

APPLICATION USAGE

Using fixed stack addresses is problematic when timer expiration is signaled by the creation of a new thread. Since it cannot be assumed that the thread created for one expiration is finished before the next expiration of the timer, it could happen that two threads use the same memory as a stack at the same time. This is invalid and produces undefined results.

RATIONALE

Practical clocks tick at a finite rate, with rates of 100 hertz and 1 000 hertz being common. The inverse of this tick rate is the clock resolution, also called the clock granularity, which in either case is expressed as a time duration, being 10 milliseconds and 1 millisecond respectively for these common rates. The granularity of practical clocks implies that if one reads a given clock twice in rapid succession, one may get the same time value twice; and that timers must wait for the next clock tick after the theoretical expiration time, to ensure that a timer never returns too soon. Note also that the granularity of the clock may be significantly coarser than the resolution of the data format used to set and get time and interval values. Also note that some implementations may choose to adjust time and/or interval values to exactly match the ticks of the underlying clock.

This volume of POSIX.1-2017 defines functions that allow an application to determine the implementation-supported resolution for the clocks and requires an implementation to document the resolution supported for timers and *nanosleep*( ) if they differ from the supported

clock resolution. This is more of a procurement issue than a runtime application issue.

If an implementation detects that the value specified by the *timerid* argument to *timer_getoverrun*( ), *timer_gettime*( ), or *timer_settime*( ) does not correspond to a timer ID returned by *timer_create*( ) but not yet deleted by *timer_delete*( ), it is recommended that the function should fail and report an [EINVAL] error.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *timer_getoverrun*( ), *timer_gettime*( ), and *timer_settime*( ) functions are marked as part of the Timers option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

The [EINVAL] error condition is updated to include the following: ``and the *it_value* member of that structure did not specify zero seconds and nanoseconds.'' This change is for IEEE PASC Interpretation 1003.1 #89.

The DESCRIPTION for *timer_getoverrun*( ) is updated to clarify that ``If no expiration signal has been delivered for the timer, or if the Realtime Signals Extension is not supported, the return value of *timer_getoverrun*( ) is unspecified''.

The **restrict** keyword is added to the *timer_settime*( ) prototype for alignment with the ISO/IEC 9899: 1999 standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/140 is applied, updating the ERRORS section so that the mandatory [EINVAL] error (``The *timerid* argument does not correspond to an ID returned by *timer_create*( ) but not yet deleted by *timer_delete*( )'') becomes optional.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/141 is applied, updating the ERRORS section to include an optional [EINVAL] error for the case when a timer is created with the notification method set to SIGEV_THREAD. APPLICATION USAGE text is also added.

Issue 7

The *timer_getoverrun*( ), *timer_gettime*( ), and *timer_settime*( ) functions are moved from the Timers option to the Base.

Functionality relating to the Realtime Signals Extension option is moved to the Base.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0370 [659] is applied.

69185 **NAME**

69186 times — get process and waited-for child process times

69187 **SYNOPSIS**

69188 `#include <sys/times.h>`

69189 `clock_t times(struct tms *buffer);`

69190 **DESCRIPTION**

69191 The *times*( ) function shall fill the **tms** structure pointed to by *buffer* with time-accounting
69192 information. The **tms** structure is defined in **<sys/times.h>**.

69193 All times are measured in terms of the number of clock ticks used.

69194 The times of a terminated child process shall be included in the *tms_cutime* and *tms_cstime*
69195 elements of the parent when *wait*( ), *waitid*( ), or *waitpid*( ) returns the process ID of this
69196 terminated child. If a child process has not waited for its children, their times shall not be
69197 included in its times.

69198 The *tms_utime* structure member is the CPU time charged for the execution of user
69199 instructions of the calling process.

69200 The *tms_stime* structure member is the CPU time charged for execution by the system on
69201 behalf of the calling process.

69202 The *tms_cutime* structure member is the sum of the *tms_utime* and *tms_cutime* times of the
69203 child processes.

69204 The *tms_cstime* structure member is the sum of the *tms_stime* and *tms_cstime* times of the
69205 child processes.

69206 **RETURN VALUE**

69207 Upon successful completion, *times*( ) shall return the elapsed real time, in clock ticks, since an
69208 arbitrary point in the past (for example, system start-up time). This point does not change from
69209 one invocation of *times*( ) within the process to another. The return value may overflow the
69210 possible range of type **clock_t**. If *times*( ) fails, (**clock_t**)–1 shall be returned and *errno* set to
69211 indicate the error.

69212 **ERRORS**

69213 The *times*( ) function shall fail if:

69214 [EOVERFLOW] The return value would overflow the range of **clock_t**.

69215 **EXAMPLES**

69216 **Timing a Database Lookup**

69217 The following example defines two functions, *start_clock*( ) and *end_clock*( ), that are used to time
69218 a lookup. It also defines variables of type **clock_t** and **tms** to measure the duration of
69219 transactions. The *start_clock*( ) function saves the beginning times given by the *times*( ) function.
69220 The *end_clock*( ) function gets the ending times and prints the difference between the two times.

```
69221 #include <sys/times.h>
69222 #include <stdio.h>
69223 ...
69224 void start_clock(void);
69225 void end_clock(char *msg);
69226 ...
69227 static clock_t st_time;
69228 static clock_t en_time;
```

```
static struct tms st_cpu;
static struct tms en_cpu;
...
void
start_clock()
{
    st_time = times(&st_cpu);
}

/* This example assumes that the result of each subtraction
   is within the range of values that can be represented in
   an integer type. */
void
end_clock(char *msg)
{
    en_time = times(&en_cpu);

    fputs(msg,stdout);
    printf("Real Time: %jd, User Time %jd, System Time %jd\n",
        (intmax_t)(en_time - st_time),
        (intmax_t)(en_cpu.tms_utime - st_cpu.tms_utime),
        (intmax_t)(en_cpu.tms_stime - st_cpu.tms_stime));
}
```

APPLICATION USAGE

Applications should use *sysconf*(_SC_CLK_TCK) to determine the number of clock ticks per second as it may vary from system to system.

RATIONALE

The accuracy of the times reported is intentionally left unspecified to allow implementations flexibility in design, from uniprocessor to multi-processor networks.

The inclusion of times of child processes is recursive, so that a parent process may collect the total times of all of its descendants. But the times of a child are only added to those of its parent when its parent successfully waits on the child. Thus, it is not guaranteed that a parent process can always see the total times of all its descendants; see also the discussion of the term ``realtime'' in *alarm*( ).

If the type **clock_t** is defined to be a signed 32-bit integer, it overflows in somewhat more than a year if there are 60 clock ticks per second, or less than a year if there are 100. There are individual systems that run continuously for longer than that. This volume of POSIX.1-2017 permits an implementation to make the reference point for the returned value be the start-up time of the process, rather than system start-up time.

The term ``charge'' in this context has nothing to do with billing for services. The operating system accounts for time used in this way. That information must be correct, regardless of how that information is used.

FUTURE DIRECTIONS

None.

NAME

timezone — difference from UTC and local standard time

SYNOPSIS

XSI
```
#include <time.h>

extern long timezone;
```

DESCRIPTION

Refer to *tzset( )*.

NAME

tmpfile — create a temporary file

SYNOPSIS

```
#include <stdio.h>

FILE *tmpfile(void);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *tmpfile*( ) function shall create a temporary file and open a corresponding stream. The file shall be automatically deleted when all references to the file are closed. The file shall be opened as in *fopen*( ) for update (*wb*+), except that implementations may restrict the permissions, either by clearing the file mode bits or setting them to the value S_IRUSR | S_IWUSR.

CX In some implementations, a permanent file may be left behind if the process calling *tmpfile*( ) is killed while it is processing a call to *tmpfile*( ).

An error message may be written to standard error if the stream cannot be opened.

RETURN VALUE

Upon successful completion, *tmpfile*( ) shall return a pointer to the stream of the file that is CX created. Otherwise, it shall return a null pointer and set *errno* to indicate the error.

ERRORS

The *tmpfile*( ) function shall fail if:

CX [EINTR] A signal was caught during *tmpfile*( ).

CX [EMFILE] All file descriptors available to the process are currently open.

CX [EMFILE] {STREAM_MAX} streams are currently open in the calling process.

CX [ENFILE] The maximum allowable number of files is currently open in the system.

CX [ENOSPC] The directory or file system which would contain the new file cannot be expanded.

CX [EOVERFLOW] The file is a regular file and the size of the file cannot be represented correctly in an object of type **off_t**.

The *tmpfile*( ) function may fail if:

CX [EMFILE] {FOPEN_MAX} streams are currently open in the calling process.

CX [ENOMEM] Insufficient storage space is available.

EXAMPLES

Creating a Temporary File

The following example creates a temporary file for update, and returns a pointer to a stream for the created file in the *fp* variable.

```
#include <stdio.h>
...
FILE *fp;

fp = tmpfile ();
```

APPLICATION USAGE

It should be possible to open at least {TMP_MAX} temporary files during the lifetime of the program (this limit may be shared with *tmpnam*( )) and there should be no limit on the number simultaneously open other than this limit and any limit on the number of open file descriptors or streams ({OPEN_MAX}, {FOPEN_MAX}, {STREAM_MAX}).

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.5 (on page 495), *fopen*( ), *mkdtemp*( ), *tmpnam*( ), *unlink*( )

XBD **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Large File Summit extensions are added.

The last two paragraphs of the DESCRIPTION were included as APPLICATION USAGE notes in previous issues.

Issue 6

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the ERRORS section, the [EOVERFLOW] condition is added. This change is to support large files.
- The [EMFILE] optional error condition is added.

The APPLICATION USAGE section is added for alignment with the ISO/IEC 9899:1999 standard.

Issue 7

Austin Group Interpretation 1003.1-2001 #025 is applied, clarifying that implementations may restrict the permissions of the file created.

SD5-XBD-ERN-4 is applied, changing the definition of the [EMFILE] error.

SD5-XSH-ERN-149 is applied, adding the mandatory [EMFILE] error condition for {STREAM_MAX} streams open.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0668 [14] is applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0372 [678] is applied.

NAME

tmpnam — create a name for a temporary file

SYNOPSIS

OB
```
#include <stdio.h>

char *tmpnam(char *s);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *tmpnam*( ) function shall generate a string that is a valid pathname that does not name an existing file. The function is potentially capable of generating {TMP_MAX} different strings, but any or all of them may already be in use by existing files and thus not be suitable return values.

The *tmpnam*( ) function generates a different string each time it is called from the same process, up to {TMP_MAX} times. If it is called more than {TMP_MAX} times, the behavior is implementation-defined.

The implementation shall behave as if no function defined in this volume of POSIX.1-2017, except *tempnam*( ), calls *tmpnam*( ).

CX The *tmpnam*( ) function need not be thread-safe if called with a NULL parameter.

RETURN VALUE

Upon successful completion, *tmpnam*( ) shall return a pointer to a string. If no suitable string can be generated, the *tmpnam*( ) function shall return a null pointer.

If the argument *s* is a null pointer, *tmpnam*( ) shall leave its result in an internal static object and return a pointer to that object. Subsequent calls to *tmpnam*( ) may modify the same object. If the argument *s* is not a null pointer, it is presumed to point to an array of at least L_tmpnam **char**s; *tmpnam*( ) shall write its result in that array and shall return the argument as its value.

ERRORS

No errors are defined.

EXAMPLES

Generating a Pathname

The following example generates a unique pathname and stores it in the array pointed to by *ptr*.

```
#include <stdio.h>
...
char pathname[L_tmpnam+1];
char *ptr;

ptr = tmpnam(pathname);
```

APPLICATION USAGE

This function only creates pathnames. It is the application's responsibility to create and remove the files.

Between the time a pathname is created and the file is opened, it is possible for some other process to create a file with the same name. Applications may find *tmpfile*( ) more useful.

Applications should use the *tmpfile*( ), *mkstemp*( ), or *mkdtemp*( ) functions instead of the obsolescent *tmpnam*( ) function.

RATIONALE

None.

FUTURE DIRECTIONS

The *tmpnam*( ) function may be removed in a future version.

SEE ALSO

NAME

tolower, tolower_l — transliterate uppercase characters to lowercase

SYNOPSIS

```
#include <ctype.h>

int tolower(int c);
CX int tolower_l(int c, locale_t locale);
```

DESCRIPTION

CX For *tolower*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *tolower*( ) and *tolower_l*( ) functions have as a domain a type **int**, the value of which is representable as an **unsigned char** or the value of EOF. If the argument has any other value, the behavior is undefined. If the argument of *tolower*( ) or *tolower_l*( ) represents an uppercase letter, and there exists a corresponding lowercase letter as defined by character type information in the current locale or in the locale represented by *locale*, respectively (category *LC_CTYPE*), the result shall be the corresponding lowercase letter. All other arguments in the domain are returned unchanged.

CX The behavior is undefined if the *locale* argument to *tolower_l*( ) is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

CX Upon successful completion, the *tolower*( ) and *tolower_l*( ) functions shall return the lowercase letter corresponding to the argument passed; otherwise, they shall return the argument unchanged.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Issue 7

The *tolower_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0671 [283] and XSH/TC1-2008/0672 [283] are applied.

NAME

toupper, toupper_l — transliterate lowercase characters to uppercase

SYNOPSIS

```
#include <ctype.h>

int toupper(int c);
CX int toupper_l(int c, locale_t locale);
```

DESCRIPTION

CX For *toupper*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *toupper*( ) and *toupper_l*( ) functions have as a domain a type **int**, the value of which is representable as an **unsigned char** or the value of EOF. If the argument has any other value, the behavior is undefined.

CX If the argument of *toupper*( ) or *toupper_l*( ) represents a lowercase letter, and there exists a
CX corresponding uppercase letter as defined by character type information in the current locale or in the locale represented by *locale*, respectively (category *LC_CTYPE*), the result shall be the corresponding uppercase letter.

All other arguments in the domain are returned unchanged.

CX The behavior is undefined if the *locale* argument to *toupper_l*( ) is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

CX Upon successful completion, *toupper*( ) and *toupper_l*( ) shall return the uppercase letter corresponding to the argument passed; otherwise, they shall return the argument unchanged.

ERRORS

No errors are defined.

EXAMPLES

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

Extensions beyond the ISO C standard are marked.

69536 **Issue 7**

69537 SD5-XSH-ERN-181 is applied, clarifying the RETURN VALUE section.

69538 The *toupper_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API
69539 Set Part 4.

69540 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0673 [283] and XSH/TC1-2008/0674
69541 [283] are applied.

69542 **NAME**

69543 towctrans, towctrans_l ‡'wide-character transliteration

69544 **SYNOPSIS**

69545
```
#include <wctype.h>
```

69546
```
wint_t towctrans(wint_t wc, wctrans_t desc);
```

69547 CX
```
wint_t towctrans_l(wint_t wc, wctrans_t desc,
    locale_t locale);
```

69548

69549 **DESCRIPTION**

69550 CX For *towctrans*( ): The functionality described on this reference page is aligned with the ISO C
69551 standard. Any conflict between the requirements described here and the ISO C standard is
69552 unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

69553 CX The *towctrans*( ) and *towctrans_l*( ) functions shall transliterate the wide-character code *wc* using
69554 the mapping described by *desc*.

69555 CX The current setting of the *LC_CTYPE* category in the current locale or in the locale represented
69556 CX by *locale*, respectively, should be the same as during the call to *wctrans*( ) or *wctrans_l*( ) that
69557 returned the value *desc*.

69558 If the value of *desc* is invalid (that is, not obtained by a call to *wctrans*( ) or *desc* is invalidated by a
69559 subsequent call to *setlocale*( ) that has affected category *LC_CTYPE*), the result is unspecified.

69560 CX If the value of *desc* is invalid (that is, not obtained by a call to *wctrans_l*( ) with the same locale
69561 object *locale*) the result is unspecified.

69562 CX An application wishing to check for error situations should set *errno* to 0 before calling
69563 *towctrans*( ) or *towctrans_l*( ).

69564 If *errno* is non-zero on return, an error has occurred.

69565 The behavior is undefined if the *locale* argument to *towctrans_l*( ) is the special locale object
69566 LC_GLOBAL_LOCALE or is not a valid locale object handle.

69567 **RETURN VALUE**

69568 CX If successful, the *towctrans*( ) and *towctrans_l*( ) functions shall return the mapped value of *wc*
69569 using the mapping described by *desc*. Otherwise, they shall return *wc* unchanged.

69570 **ERRORS**

69571 These functions may fail if:

69572 CX [EINVAL] *desc* contains an invalid transliteration descriptor.

69573 **EXAMPLES**

69574 None.

69575 **APPLICATION USAGE**

69576 The strings `"tolower"` and `"toupper"` are reserved for the standard mapping names. In the
69577 table below, the functions in the left column are equivalent to the functions in the right column.

69578 `towlower(wc)`	`towctrans(wc, wctrans("tolower"))`
69579 `towlower_l(wc, locale)`	`towctrans_l(wc, wctrans("tolower"), locale)`
69580 `towupper(wc)`	`towctrans(wc, wctrans("toupper"))`
69581 `towupper_l(wc, locale)`	`towctrans_l(wc, wctrans("toupper"), locale)`

69582 **RATIONALE**

69583 None.

69584 **FUTURE DIRECTIONS**

69585 None.

69586 **SEE ALSO**

69587 *towlower( )*, *towupper( )*, *wctrans( )*

69595 API Set Part 4.

69596 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0675 [302], XSH/TC1-2008/0676 [283],
69597 and XSH/TC1-2008/0677 [283] are applied.

NAME

towlower, towlower_l — transliterate uppercase wide-character code to lowercase

SYNOPSIS

```
#include <wctype.h>

wint_t towlower(wint_t wc);
CX wint_t towlower_l(wint_t wc, locale_t locale);
```

DESCRIPTION

CX For *towlower*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *towlower*( ) and *towlower_l*( ) functions have as a domain a type **wint_t**, the value of which the application shall ensure is a character representable as a **wchar_t**, and a wide-character code corresponding to a valid character in the locale used by the function or the value of WEOF. If CX the argument has any other value, the behavior is undefined. If the argument of *towlower*( ) or *towlower_l*( ) represents an uppercase wide-character code, and there exists a corresponding CX lowercase wide-character code as defined by character type information in the current locale or in the locale represented by *locale*, respectively (category *LC_CTYPE*), the result shall be the corresponding lowercase wide-character code. All other arguments in the domain are returned unchanged.

CX The behavior is undefined if the *locale* argument to *towlower_l*( ) is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

CX Upon successful completion, the *towlower*( ) and *towlower_l*( ) functions shall return the lowercase letter corresponding to the argument passed; otherwise, they shall return the argument unchanged.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The following change has been made in this version for alignment with ISO/IEC 9899: 1990/Amendment 1: 1995 (E):

> The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The normative text is updated to avoid use of the term ``must'' for application requirements.

Issue 7

The *towlower_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0678 [302], XSH/TC1-2008/0679 [283], and XSH/TC1-2008/0680 [283] are applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0373 [685] is applied.

NAME

towupper, towupper_l — transliterate lowercase wide-character code to uppercase

SYNOPSIS

```
#include <wctype.h>

wint_t towupper(wint_t wc);
CX wint_t towupper_l(wint_t wc, locale_t locale);
```

DESCRIPTION

CX For *towupper*(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *towupper*() and *towupper_l*() functions have as a domain a type **wint_t**, the value of which the application shall ensure is a character representable as a **wchar_t**, and a wide-character code corresponding to a valid character in the locale used by the function or the value of WEOF. If CX the argument has any other value, the behavior is undefined. If the argument of *towupper*() or *towupper_l*() represents a lowercase wide-character code, and there exists a corresponding CX uppercase wide-character code as defined by character type information in the current locale or in the locale represented by *locale*, respectively (category *LC_CTYPE*), the result shall be the corresponding uppercase wide-character code. All other arguments in the domain are returned unchanged.

CX The behavior is undefined if the *locale* argument to *towupper_l*() is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

CX Upon successful completion, the *towupper*() and *towupper_l*() functions shall return the uppercase letter corresponding to the argument passed. Otherwise, they shall return the argument unchanged.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0374 [685] is applied.

NAME

trunc, truncf, truncl — round to truncated integer value

SYNOPSIS

```
#include <math.h>

double trunc(double x);
float truncf(float x);
long double truncl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

These functions shall round their argument to the integer value, in floating format, nearest to but no larger in magnitude than the argument.

RETURN VALUE

Upon successful completion, these functions shall return the truncated integer value.

MX The result shall have the same sign as *x*.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0 or ±Inf, *x* shall be returned.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The integral value returned by these functions need not be expressible as an **intmax_t**. The return value should be tested before assigning it to an integer type to avoid the undefined results of an integer overflow.

These functions may raise the inexact floating-point exception if the result differs in value from the argument.

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899: 1999 standard.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0684 [346] is applied.

69742 **NAME**

69743 truncate — truncate a file to a specified length

69744 **SYNOPSIS**

69745 ```
#include <unistd.h>
```

69746 ```
int truncate(const char *path, off_t length);
```

69747 **DESCRIPTION**

69748 The *truncate*( ) function shall cause the regular file named by *path* to have a size which shall be
69749 equal to *length* bytes.

69750 If the file previously was larger than *length*, the extra data is discarded. If the file was previously
69751 shorter than *length*, its size is increased, and the extended area appears as if it were zero-filled.

69752 The application shall ensure that the process has write permission for the file.

69753 XSI If the request would cause the file size to exceed the soft file size limit for the process, the
69754 request shall fail and the implementation shall generate the SIGXFSZ signal for the process.

69755 The *truncate*( ) function shall not modify the file offset for any open file descriptions associated
69756 with the file. Upon successful completion, *truncate*( ) shall mark for update the last data
69757 modification and last file status change timestamps of the file, and the S_ISUID and S_ISGID bits
69758 of the file mode may be cleared.

69759 **RETURN VALUE**

69760 Upon successful completion, *truncate*( ) shall return 0. Otherwise, −1 shall be returned, and *errno*
69761 set to indicate the error.

69762 **ERRORS**

69763 The *truncate*( ) function shall fail if:

69764 [EINTR] A signal was caught during execution.

69765 [EINVAL] The *length* argument was less than 0.

69766 [EFBIG] or [EINVAL]
69767 The *length* argument was greater than the maximum file size.

69768 [EIO] An I/O error occurred while reading from or writing to a file system.

69769 [EACCES] A component of the path prefix denies search permission, or write permission
69770 is denied on the file.

69771 [EISDIR] The named file is a directory.

69772 [ELOOP] A loop exists in symbolic links encountered during resolution of the *path*
69773 argument.

69774 [ENAMETOOLONG]
69775 The length of a component of a pathname is longer than {NAME_MAX}.

69776 [ENOENT] A component of *path* does not name an existing file or *path* is an empty string.

69777 [ENOTDIR] A component of the path prefix names an existing file that is neither a
69778 directory nor a symbolic link to a directory, or the *path* argument contains at
69779 least one non-<slash> character and ends with one or more trailing <slash>
69780 characters and the last pathname component names an existing file that is
69781 neither a directory nor a symbolic link to a directory.

[EROFS] The named file resides on a read-only file system.

The *truncate*( ) function may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.

[ENAMETOOLONG]
The length of a pathname exceeds {PATH_MAX}, or pathname resolution of a symbolic link produced an intermediate result with a length that exceeds {PATH_MAX}.

EXAMPLES

None.

APPLICATION USAGE

XBD **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Large File Summit extensions are added.

Issue 6

This reference page is split out from the *ftruncate*( ) reference page.

The normative text is updated to avoid use of the term ``must'' for application requirements.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

Issue 7

Austin Group Interpretation 1003.1-2001 #143 is applied.

The *truncate*( ) function is moved from the XSI option to the Base.

Changes are made related to support for finegrained timestamps.

The [ENOTDIR] error condition is clarified to cover the condition where the last component of a pathname exists but is not a directory or a symbolic link to a directory.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0685 [324] is applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0375 [489] is applied.

69819 **NAME**

69820 truncf, truncl — round to truncated integer value

69821 **SYNOPSIS**

69822 `#include <math.h>`

69823 `float truncf(float x);`

69824 `long double truncl(long double x);`

69825 **DESCRIPTION**

69826 Refer to *trunc*( ).

NAME

tsearch — search a binary search tree

SYNOPSIS

XSI

```
#include <search.h>

void *tsearch(const void *key, void **rootp,
    int (*compar)(const void *, const void *));
```

DESCRIPTION

Refer to *tdelete( )*.

69835 **NAME**

69836 ttyname, ttyname_r ‡'find the pathname of a terminal

69837 **SYNOPSIS**

69838 ```
#include <unistd.h>

char *ttyname(int fildes);
int ttyname_r(int fildes, char *name, size_t namesize);
```

69841 **DESCRIPTION**

69842 The *ttyname*( ) function shall return a pointer to a string containing a null-terminated pathname
69843 of the terminal associated with file descriptor *fildes*. The application shall not modify the string
69844 returned. The returned pointer might be invalidated or the string content might be overwritten
69845 by a subsequent call to *ttyname*( ). The returned pointer and the string content might also be
69846 invalidated if the calling thread is terminated.

69847 The *ttyname*( ) function need not be thread-safe.

69848 The *ttyname_r*( ) function shall store the null-terminated pathname of the terminal associated
69849 with the file descriptor *fildes* in the character array referenced by *name*. The array is *namesize*
69850 characters long and should have space for the name and the terminating null character. The
69851 maximum length of the terminal name shall be {TTY_NAME_MAX}.

69852 **RETURN VALUE**

69853 Upon successful completion, *ttyname*( ) shall return a pointer to a string. Otherwise, a null
69854 pointer shall be returned and *errno* set to indicate the error.

69855 If successful, the *ttyname_r*( ) function shall return zero. Otherwise, an error number shall be
69856 returned to indicate the error.

69857 **ERRORS**

69858 The *ttyname*( ) function may fail if:

69859 [EBADF] The *fildes* argument is not a valid file descriptor.

69860 [ENOTTY] The file associated with the *fildes* argument is not a terminal.

69861 The *ttyname_r*( ) function may fail if:

69862 [EBADF] The *fildes* argument is not a valid file descriptor.

69863 [ENOTTY] The file associated with the *fildes* argument is not a terminal.

69864 [ERANGE] The value of *namesize* is smaller than the length of the string to be returned
69865 including the terminating null character.

69866 **EXAMPLES**

69867 None.

69868 **APPLICATION USAGE**

69869 None.

69870 **RATIONALE**

69871 The term ``terminal'' is used instead of the historical term ``terminal device'' in order to avoid a
69872 reference to an undefined term.

69873 The thread-safe version places the terminal name in a user-supplied buffer and returns a non-
69874 zero value if it fails. The non-thread-safe version may return the name in a static data area that
69875 may be overwritten by each call.

  
```

FUTURE DIRECTIONS

None.

SEE ALSO

XBD **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The *ttyname_r*( ) function is included for alignment with the POSIX Threads Extension.

A note indicating that the *ttyname*( ) function need not be reentrant is added to the DESCRIPTION.

Issue 6

The *ttyname_r*( ) function is marked as part of the Thread-Safe Functions option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The statement that *errno* is set on error is added.
- The [EBADF] and [ENOTTY] optional error conditions are added.

Issue 7

Austin Group Interpretation 1003.1-2001 #156 is applied.

SD5-XSH-ERN-100 is applied, correcting the definition of the [ENOTTY] error condition.

The *ttyname_r*( ) function is moved from the Thread-Safe Functions option to the Base.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0686 [75] is applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0376 [656] is applied.

NAME

twalk — traverse a binary search tree

SYNOPSIS

XSI

```
#include <search.h>

void twalk(const void *root,
    void (*action)(const void *, VISIT, int ));
```

DESCRIPTION

Refer to *tdelete( )*.

NAME

daylight, timezone, tzname, tzset ‡'set timezone conversion information

SYNOPSIS

```
#include <time.h>

extern int daylight;
extern long timezone;
extern char *tzname[2];
void tzset(void);
```

DESCRIPTION

The *tzset*( ) function shall use the value of the environment variable *TZ* to set time conversion information used by *ctime*( ), *localtime*( ), *mktime*( ), and *strftime*( ). If *TZ* is absent from the environment, implementation-defined default timezone information shall be used.

The *tzset*( ) function shall set the external variable *tzname* as follows:

```
tzname[0] = "std";
tzname[1] = "dst";
```

where *std* and *dst* are as described in XBD Chapter 8 (on page 173).

The *tzset*( ) function also shall set the external variable *daylight* to 0 if Daylight Savings Time conversions should never be applied for the timezone in use; otherwise, non-zero. The external variable *timezone* shall be set to the difference, in seconds, between Coordinated Universal Time (UTC) and local standard time.

If a thread accesses *tzname*, *daylight*, or *timezone* directly while another thread is in a call to *tzset*( ), or to any function that is required or allowed to set timezone information as if by calling *tzset*( ), the behavior is undefined.

RETURN VALUE

The *tzset*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

Example *TZ* variables and their timezone differences are given in the table below:

TZ	*timezone*
EST5EDT	5*60*60
GMT0	0*60*60
JST-9	–9*60*60
MET-1MEST	–1*60*60
MST7MDT	7*60*60
PST8PDT	8*60*60

APPLICATION USAGE

Since the *ctime*( ), *localtime*( ), *mktime*( ), *strftime*( ), and *strftime_l*( ) functions are required to set timezone information as if by calling *tzset*( ), there is no need for an explicit *tzset*( ) call before using these functions. However, portable applications should call *tzset*( ) explicitly before using *ctime_r*( ) or *localtime_r*( ) because setting timezone information is optional for those functions.

69947 **RATIONALE**

69948 None.

69949 **FUTURE DIRECTIONS**

69950 None.

69951 **SEE ALSO**

69952 *ctime( )*, *localtime( )*, *mktime( )*, *strftime( )*

69953 XBD Chapter 8 (on page 173), **<time.h>**

69954 **CHANGE HISTORY**

69955 First released in Issue 1. Derived from Issue 1 of the SVID.

69956 **Issue 6**

69957 The example is corrected.

69958 **Issue 7**

69959 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0377 [880] is applied.

NAME

ulimit — get and set process limits

SYNOPSIS

OB XSI
```
#include <ulimit.h>

long ulimit(int cmd, ...);
```

DESCRIPTION

The *ulimit*( ) function shall control process limits. The process limits that can be controlled by this function include the maximum size of a single file that can be written (this is equivalent to using *setrlimit*( ) with RLIMIT_FSIZE). The *cmd* values, defined in **<ulimit.h>**, include:

UL_GETFSIZE Return the file size limit (RLIMIT_FSIZE) of the process. The limit shall be in units of 512-byte blocks and shall be inherited by child processes. Files of any size can be read. The return value shall be the integer part of the soft file size limit divided by 512. If the result cannot be represented as a **long**, the result is unspecified.

UL_SETFSIZE Set the file size limit for output operations of the process to the value of the second argument, taken as a **long**, multiplied by 512. If the result would overflow an **rlim_t**, the actual value set is unspecified. Any process may decrease its own limit, but only a process with appropriate privileges may increase the limit. The return value shall be the integer part of the new file size limit divided by 512.

The *ulimit*( ) function shall not change the setting of *errno* if successful.

As all return values are permissible in a successful situation, an application wishing to check for error situations should set *errno* to 0, then call *ulimit*( ), and, if it returns –1, check to see if *errno* is non-zero.

RETURN VALUE

Upon successful completion, *ulimit*( ) shall return the value of the requested limit. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *ulimit*( ) function shall fail and the limit shall be unchanged if:

[EINVAL] The *cmd* argument is not valid.

[EPERM] A process not having appropriate privileges attempts to increase its file size limit.

EXAMPLES

None.

APPLICATION USAGE

Since the *ulimit*( ) function uses type **long** rather than **rlim_t**, this function is not sufficient for file sizes on many current systems. Applications should use the *getrlimit*( ) or *setrlimit*( ) functions instead of the obsolescent *ulimit*( ) function.

RATIONALE

None.

70000 **FUTURE DIRECTIONS**

70001 The *ulimit*( ) function may be removed in a future version.

70002 **SEE ALSO**

70003 *exec*, *getrlimit*( ), *write*( )

70004 XBD **<ulimit.h>**

70005 **CHANGE HISTORY**

70006 First released in Issue 1. Derived from Issue 1 of the SVID.

70007 **Issue 5**

70008 In the description of UL_SETFSIZE, the text is corrected to refer to **rlim_t** rather than the
70009 spurious **rlimit_t**.

70010 The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

70011 **Issue 7**

70012 The *ulimit*( ) function is marked obsolescent.

70013 **NAME**

70014 umask — set and get the file mode creation mask

70015 **SYNOPSIS**

70016 `#include <sys/stat.h>`

70017 `mode_t umask(mode_t cmask);`

70018 **DESCRIPTION**

70019 The *umask*( ) function shall set the file mode creation mask of the process to *cmask* and return the
70020 previous value of the mask. Only the file permission bits of *cmask* (see **<sys/stat.h>**) are used; the
70021 meaning of the other bits is implementation-defined.

70022 The file mode creation mask of the process is used to turn off permission bits in the *mode*
70023 argument supplied during calls to the following functions:

70024 *open*( ), *openat*( ), *creat*( ), *mkdir*( ), *mkdirat*( ), *mkfifo*( ), and *mkfifoat*( )

70025 XSI *mknod*( ), *mknodat*( )

70026 MSG *mq_open*( )

70027 *sem_open*( )

70028 Bit positions that are set in *cmask* are cleared in the mode of the created file.

70029 **RETURN VALUE**

70030 The file permission bits in the value returned by *umask*( ) shall be the previous value of the file
70031 mode creation mask. The state of any other bits in that value is unspecified, except that a
70032 subsequent call to *umask*( ) with the returned value as *cmask* shall leave the state of the mask the
70033 same as its state before the first call, including any unspecified use of those bits.

70034 **ERRORS**

70035 No errors are defined.

70036 **EXAMPLES**

70037 None.

70038 **APPLICATION USAGE**

70039 None.

70040 **RATIONALE**

70041 Unsigned argument and return types for *umask*( ) were proposed. The return type and the
70042 argument were both changed to **mode_t**.

70043 Historical implementations have made use of additional bits in *cmask* for their implementation-
70044 defined purposes. The addition of the text that the meaning of other bits of the field is
70045 implementation-defined permits these implementations to conform to this volume of
70046 POSIX.1-2017.

70047 **FUTURE DIRECTIONS**

70048 None.

70049 **SEE ALSO**

70050 *creat*( ), *exec*, *mkdir*( ), *mkfifo*( ), *mknod*( ), *mq_open*( ), *open*( ), *sem_open*( )

70051 XBD **<sys/stat.h>**, **<sys/types.h>**

70052 **CHANGE HISTORY**

70053 First released in Issue 1. Derived from Issue 1 of the SVID.

70054 **Issue 6**

70055 In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

70056 The following new requirements on POSIX implementations derive from alignment with the
70057 Single UNIX Specification:

70058 The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was
70059 required for conforming implementations of previous POSIX specifications, it was not
70060 required for UNIX applications.

70061 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/143 is applied, adding the *mknod*( ),
70062 *mq_open*( ), and *sem_open*( ) functions to the DESCRIPTION and SEE ALSO sections.

NAME

uname — get the name of the current system

SYNOPSIS

```
#include <sys/utsname.h>

int uname(struct utsname *name);
```

DESCRIPTION

The *uname*( ) function shall store information identifying the current system in the structure pointed to by *name*.

The *uname*( ) function uses the **utsname** structure defined in **<sys/utsname.h>**.

The *uname*( ) function shall return a string naming the current system in the character array *sysname*. Similarly, *nodename* shall contain the name of this node within an implementation-defined communications network. The arrays *release* and *version* shall further identify the operating system. The array *machine* shall contain a name that identifies the hardware that the system is running on.

The format of each member is implementation-defined.

RETURN VALUE

Upon successful completion, a non-negative value shall be returned. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The inclusion of the *nodename* member in this structure does not imply that it is sufficient information for interfacing to communications networks.

RATIONALE

The values of the structure members are not constrained to have any relation to the version of this volume of POSIX.1-2017 implemented in the operating system. An application should instead depend on _POSIX_VERSION and related constants defined in **<unistd.h>**.

This volume of POSIX.1-2017 does not define the sizes of the members of the structure and permits them to be of different sizes, although most implementations define them all to be the same size: eight bytes plus one byte for the string terminator. That size for *nodename* is not enough for use with many networks.

The *uname*( ) function originated in System III, System V, and related implementations, and it does not exist in Version 7 or 4.3 BSD. The values it returns are set at system compile time in those historical implementations.

4.3 BSD has *gethostname*( ) and *gethostid*( ), which return a symbolic name and a numeric value, respectively. There are related *sethostname*( ) and *sethostid*( ) functions that are used to set the values the other two functions return. The former functions are included in this specification, the latter are not.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

NAME

ungetc — push byte back into input stream

SYNOPSIS

```
#include <stdio.h>

int ungetc(int c, FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *ungetc*( ) function shall push the byte specified by *c* (converted to an **unsigned char**) back onto the input stream pointed to by *stream*. The pushed-back bytes shall be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening CX call (with the stream pointed to by *stream*) to a file-positioning function (*fseek*( ), *fseeko*( ), CX *fsetpos*( ), or *rewind*( )) or *fflush*( ) shall discard any pushed-back bytes for the stream. The external storage corresponding to the stream shall be unchanged.

One byte of push-back shall be provided. If *ungetc*( ) is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.

If the value of *c* equals that of the macro EOF, the operation shall fail and the input stream shall be left unchanged.

A successful call to *ungetc*( ) shall clear the end-of-file indicator for the stream. The value of the file-position indicator for the stream after all pushed-back bytes have been read, or discarded by CX calling *fseek*( ), *fseeko*( ), *fsetpos*( ), or *rewind*( ) (but not *fflush*( )), shall be the same as it was before the bytes were pushed back. The file-position indicator is decremented by each successful call to *ungetc*( ); if its value was 0 before a call, its value is unspecified after the call.

RETURN VALUE

Upon successful completion, *ungetc*( ) shall return the byte pushed back after conversion. Otherwise, it shall return EOF.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0687 [87,93], XSH/TC1-2008/0688 [87], and XSH/TC1-2008/0689 [14] are applied.

NAME

ungetwc — push wide-character code back into the input stream

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

wint_t ungetwc(wint_t wc, FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *ungetwc*( ) function shall push the character corresponding to the wide-character code specified by *wc* back onto the input stream pointed to by *stream*. The pushed-back characters shall be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by *stream*) to a file-positioning function (*fseek*( ), CX *fseeko*( ), *fsetpos*( ), or *rewind*( )) or *fflush*( ) shall discard any pushed-back characters for the stream. The external storage corresponding to the stream is unchanged.

At least one character of push-back shall be provided. If *ungetwc*( ) is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.

If the value of *wc* equals that of the macro WEOF, the operation shall fail and the input stream shall be left unchanged.

A successful call to *ungetwc*( ) shall clear the end-of-file indicator for the stream. The value of the file-position indicator for the stream after all pushed-back characters have been read, or CX discarded by calling *fseek*( ), *fseeko*( ), *fsetpos*( ), or *rewind*( ) (but not *fflush*( )), shall be the same as it was before the characters were pushed back. The file-position indicator is decremented (by one or more) by each successful call to *ungetwc*( ); if its value was 0 before a call, its value is unspecified after the call.

RETURN VALUE

Upon successful completion, *ungetwc*( ) shall return the wide-character code corresponding to the pushed-back character. Otherwise, it shall return WEOF.

ERRORS

The *ungetwc*( ) function may fail if:

CX [EILSEQ] An invalid character sequence is detected, or a wide-character code does not correspond to a valid character.

NAME

unlink, unlinkat — remove a directory entry

SYNOPSIS

```
#include <unistd.h>

int unlink(const char *path);
```

OH
```
#include <fcntl.h>

int unlinkat(int fd, const char *path, int flag);
```

DESCRIPTION

The *unlink*( ) function shall remove a link to a file. If *path* names a symbolic link, *unlink*( ) shall remove the symbolic link named by *path* and shall not affect any file or directory named by the contents of the symbolic link. Otherwise, *unlink*( ) shall remove the link named by the pathname pointed to by *path* and shall decrement the link count of the file referenced by the link.

When the file's link count becomes 0 and no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible. If one or more processes have the file open when the last link is removed, the link shall be removed before *unlink*( ) returns, but the removal of the file contents shall be postponed until all references to the file are closed.

The *path* argument shall not name a directory unless the process has appropriate privileges and the implementation supports using *unlink*( ) on directories.

Upon successful completion, *unlink*( ) shall mark for update the last data modification and last file status change timestamps of the parent directory. Also, if the file's link count is not 0, the last file status change timestamp of the file shall be marked for update.

The *unlinkat*( ) function shall be equivalent to the *unlink*( ) or *rmdir*( ) function except in the case where *path* specifies a relative path. In this case the directory entry to be removed is determined relative to the directory associated with the file descriptor *fd* instead of the current working directory. If the access mode of the open file description associated with the file descriptor is not O_SEARCH, the function shall check whether directory searches are permitted using the current permissions of the directory underlying the file descriptor. If the access mode is O_SEARCH, the function shall not perform the check.

Values for *flag* are constructed by a bitwise-inclusive OR of flags from the following list, defined in **<fcntl.h>**:

AT_REMOVEDIR
: Remove the directory entry specified by *fd* and *path* as a directory, not a normal file.

If *unlinkat*( ) is passed the special value AT_FDCWD in the *fd* parameter, the current working directory shall be used and the behavior shall be identical to a call to *unlink*( ) or *rmdir*( ) respectively, depending on whether or not the AT_REMOVEDIR bit is set in *flag*.

RETURN VALUE

Upon successful completion, these functions shall return 0. Otherwise, these functions shall return –1 and set *errno* to indicate the error. If –1 is returned, the named file shall not be changed.

ERRORS

These functions shall fail and shall not unlink the file if:

[EACCES] Search permission is denied for a component of the path prefix, or write permission is denied on the directory containing the directory entry to be removed.

70251 [EBUSY] The file named by the *path* argument cannot be unlinked because it is being
70252 used by the system or another process and the implementation considers this
70253 an error.

70254 [ELOOP] A loop exists in symbolic links encountered during resolution of the *path*
70255 argument.

70256 [ENAMETOOLONG]
70257 The length of a component of a pathname is longer than {NAME_MAX}.

70258 [ENOENT] A component of *path* does not name an existing file or *path* is an empty string.

70259 [ENOTDIR] A component of the path prefix names an existing file that is neither a
70260 directory nor a symbolic link to a directory, or the *path* argument contains at
70261 least one non-<slash> character and ends with one or more trailing <slash>
70262 characters and the last pathname component names an existing file that is
70263 neither a directory nor a symbolic link to a directory.

70264 [EPERM] The file named by *path* is a directory, and either the calling process does not
70265 have appropriate privileges, or the implementation prohibits using *unlink*( ) on
70266 directories.

70267 XSI [EPERM] or [EACCES]
70268 The S_ISVTX flag is set on the directory containing the file referred to by the
70269 *path* argument and the process does not satisfy the criteria specified in XBD
70270 Section 4.3 (on page 108).

70271 [EROFS] The directory entry to be unlinked is part of a read-only file system.

70272 The *unlinkat*( ) function shall fail if:

70273 [EACCES] The access mode of the open file description associated with *fd* is not
70274 O_SEARCH and the permissions of the directory underlying *fd* do not permit
70275 directory searches.

70276 [EBADF] The *path* argument does not specify an absolute path and the *fd* argument is
70277 neither AT_FDCWD nor a valid file descriptor open for reading or searching.

70278 [ENOTDIR] The *path* argument is not an absolute path and *fd* is a file descriptor associated
70279 with a non-directory file.

70280 [EEXIST] or [ENOTEMPTY]
70281 The *flag* parameter has the AT_REMOVEDIR bit set and the *path* argument
70282 names a directory that is not an empty directory, or there are hard links to the
70283 directory other than dot or a single entry in dot-dot.

70284 [ENOTDIR] The *flag* parameter has the AT_REMOVEDIR bit set and *path* does not name a
70285 directory.

70286 These functions may fail and not unlink the file if:

70287 XSI [EBUSY] The file named by *path* is a named STREAM.

70288 [ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during
70289 resolution of the *path* argument.

70290 [ENAMETOOLONG]
70291 The length of a pathname exceeds {PATH_MAX}, or pathname resolution of a
70292 symbolic link produced an intermediate result with a length that exceeds
70293 {PATH_MAX}.

[ETXTBSY] The entry to be unlinked is the last directory entry to a pure procedure (shared text) file that is being executed.

The *unlinkat*( ) function may fail if:

[EINVAL] The value of the *flag* argument is not valid.

EXAMPLES

Removing a Link to a File

The following example shows how to remove a link to a file named **/home/cnd/mod1** by removing the entry named **/modules/pass1**.

```
#include <unistd.h>

char *path = "/modules/pass1";
int   status;
...
status = unlink(path);
```

Checking for an Error

The following example fragment creates a temporary password lock file named **LOCKFILE**, which is defined as **/etc/ptmp**, and gets a file descriptor for it. If the file cannot be opened for writing, *unlink*( ) is used to remove the link between the file descriptor and **LOCKFILE**.

```
#include <sys/types.h>
#include <stdio.h>
#include <fcntl.h>
#include <errno.h>
#include <unistd.h>
#include <sys/stat.h>

#define LOCKFILE "/etc/ptmp"

int pfd;  /* Integer for file descriptor returned by open call. */
FILE *fpfd;  /* File pointer for use in putpwent(). */
...
/* Open password Lock file. If it exists, this is an error. */
if ((pfd = open(LOCKFILE, O_WRONLY| O_CREAT | O_EXCL, S_IRUSR
    | S_IWUSR | S_IRGRP | S_IROTH)) == -1)  {
    fprintf(stderr, "Cannot open /etc/ptmp. Try again later.\n");
    exit(1);
}

/* Lock file created; proceed with fdopen of lock file so that
   putpwent() can be used.
 */
if ((fpfd = fdopen(pfd, "w")) == NULL) {
    close(pfd);
    unlink(LOCKFILE);
    exit(1);
}
```

70335 **Replacing Files**

70336 The following example fragment uses *unlink*( ) to discard links to files, so that they can be
70337 replaced with new versions of the files. The first call removes the link to **LOCKFILE** if an error
70338 occurs. Successive calls remove the links to **SAVEFILE** and **PASSWDFILE** so that new links can
70339 be created, then removes the link to **LOCKFILE** when it is no longer needed.

```
70340 #include <sys/types.h>
70341 #include <stdio.h>
70342 #include <fcntl.h>
70343 #include <errno.h>
70344 #include <unistd.h>
70345 #include <sys/stat.h>

70346 #define LOCKFILE "/etc/ptmp"
70347 #define PASSWDFILE "/etc/passwd"
70348 #define SAVEFILE "/etc/opasswd"
70349 ...
70350 /* If no change was made, assume error and leave passwd unchanged. */
70351 if (!valid_change) {
70352     fprintf(stderr, "Could not change password for user %s\n", user);
70353     unlink(LOCKFILE);
70354     exit(1);
70355 }

70356 /* Change permissions on new password file. */
70357 chmod(LOCKFILE, S_IRUSR | S_IRGRP | S_IROTH);

70358 /* Remove saved password file. */
70359 unlink(SAVEFILE);

70360 /* Save current password file. */
70361 link(PASSWDFILE, SAVEFILE);

70362 /* Remove current password file. */
70363 unlink(PASSWDFILE);

70364 /* Save new password file as current password file. */
70365 link(LOCKFILE,PASSWDFILE);

70366 /* Remove lock file. */
70367 unlink(LOCKFILE);

70368 exit(0);
```

70369 **APPLICATION USAGE**

70370 Applications should use *rmdir*( ) to remove a directory.

70371 **RATIONALE**

70372 Unlinking a directory is restricted to the superuser in many historical implementations for
70373 reasons given in *link*( ) (see also *rename*( )).

70374 The meaning of [EBUSY] in historical implementations is ``mount point busy''. Since this volume
70375 of POSIX.1-2017 does not cover the system administration concepts of mounting and
70376 unmounting, the description of the error was changed to ``resource busy''. (This meaning is used
70377 by some device drivers when a second process tries to open an exclusive use device.) The
70378 wording is also intended to allow implementations to refuse to remove a directory if it is the root
70379 or current working directory of any process.

The standard developers reviewed TR 24715-2006 and noted that LSB-conforming implementations may return [EISDIR] instead of [EPERM] when unlinking a directory. A change to permit this behavior by changing the requirement for [EPERM] to [EPERM] or [EISDIR] was considered, but decided against since it would break existing strictly conforming and conforming applications. Applications written for portability to both POSIX.1-2017 and the LSB should be prepared to handle either error code.

The purpose of the *unlinkat*( ) function is to remove directory entries in directories other than the current working directory without exposure to race conditions. Any part of the path of a file could be changed in parallel to a call to *unlink*( ), resulting in unspecified behavior. By opening a file descriptor for the target directory and using the *unlinkat*( ) function it can be guaranteed that the removed directory entry is located relative to the desired directory.

FUTURE DIRECTIONS

None.

XBD Section 4.3 (on page 108), **<fcntl.h>**, **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The [EBUSY] error is added to the optional part of the ERRORS section.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the effect is specified if *path* specifies a symbolic link.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.
- The [ETXTBSY] optional error condition is added.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

The normative text is updated to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #143 is applied.

Austin Group Interpretation 1003.1-2001 #181 is applied, updating the requirements for operations when the S_ISVTX bit is set.

Text arising from the LSB Conflicts TR is added to the RATIONALE about the use of [EPERM] and [EISDIR].

The *unlinkat*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 2.

Changes are made related to support for finegrained timestamps.

Changes are made to allow a directory to be opened for searching.

The [ENOTDIR] error condition is clarified to cover the condition where the last component of a pathname exists but is not a directory or a symbolic link to a directory.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0693 [461], XSH/TC1-2008/0694 [324], XSH/TC1-2008/0695 [278], and XSH/TC1-2008/0696 [278] are applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0378 [873], XSH/TC2-2008/0379 [591], XSH/TC2-2008/0380 [817], and XSH/TC2-2008/0381 [817] are applied.

NAME

unlockpt ‡'unlock a pseudo-terminal master/slave pair

SYNOPSIS

XSI
```
#include <stdlib.h>

int unlockpt(int fildes);
```

DESCRIPTION

The *unlockpt*( ) function shall unlock the slave pseudo-terminal device associated with the master to which *fildes* refers.

Conforming applications shall ensure that they call *unlockpt*( ) before opening the slave side of a pseudo-terminal device.

RETURN VALUE

Upon successful completion, *unlockpt*( ) shall return 0. Otherwise, it shall return –1 and set *errno* to indicate the error.

ERRORS

The *unlockpt*( ) function may fail if:

[EBADF] The *fildes* argument is not a file descriptor open for writing.

[EINVAL] The *fildes* argument is not associated with a master pseudo-terminal device.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0697 [96] is applied.

NAME

unsetenv — remove an environment variable

SYNOPSIS

CX
```
#include <stdlib.h>

int unsetenv(const char *name);
```

DESCRIPTION

The *unsetenv*( ) function shall remove an environment variable from the environment of the calling process. The *name* argument points to a string, which is the name of the variable to be removed. The named argument shall not contain an '=' character. If the named variable does not exist in the current environment, the environment shall be unchanged and the function is considered to have completed successfully.

The *unsetenv*( ) function shall update the list of pointers to which *environ* points.

The *unsetenv*( ) function need not be thread-safe.

RETURN VALUE

Upon successful completion, zero shall be returned. Otherwise, –1 shall be returned, *errno* set to indicate the error, and the environment shall be unchanged.

ERRORS

The *unsetenv*( ) function shall fail if:

[EINVAL] The *name* argument points to an empty string, or points to a string containing an '=' character.

EXAMPLES

None.

APPLICATION USAGE

None.

CHANGE HISTORY

First released in Issue 6. Derived from the IEEE P1003.1a draft standard.

Issue 7

Austin Group Interpretation 1003.1-2001 #156 is applied.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0698 [167] and XSH/TC1-2008/0699 [185] are applied.

70499 **NAME**

70500 uselocale — use locale in current thread

70501 **SYNOPSIS**

70502 CX
```
#include <locale.h>

locale_t uselocale(locale_t newloc);
```
70503

70504 **DESCRIPTION**

70505 The *uselocale*( ) function shall set or query the current locale for the calling thread.

70506 The value for the *newloc* argument shall be one of the following:

70507 1. A value returned by the *newlocale*( ) or *duplocale*( ) functions

70508 2. The special locale object descriptor LC_GLOBAL_LOCALE

70509 3. (**locale_t**)0

70510 If the *newloc* argument is (**locale_t**)0, the current locale shall not be changed; this value can be
70511 used to query the current locale setting. If the *newloc* argument is LC_GLOBAL_LOCALE, any
70512 thread-local locale for the calling thread shall be uninstalled; the thread shall again use the
70513 global locale as the current locale, and changes to the global locale shall affect the thread.
70514 Otherwise, the locale represented by *newloc* shall be installed as a thread-local locale to be used
70515 as the current locale for the calling thread.

70516 Once the *uselocale*( ) function has been called to install a thread-local locale, the behavior of every
70517 interface using data from the current locale shall be affected for the calling thread. The current
70518 locale for other threads shall remain unchanged.

70519 **RETURN VALUE**

70520 Upon successful completion, the *uselocale*( ) function shall return a handle for the thread-local
70521 locale that was in use as the current locale for the calling thread on entry to the function, or
70522 LC_GLOBAL_LOCALE if no thread-local locale was in use. Otherwise, *uselocale*( ) shall return
70523 (**locale_t**)0 and set *errno* to indicate the error.

70524 **ERRORS**

70525 The *uselocale*( ) function may fail if:

70526 [EINVAL] *newloc* is not a valid locale object and is not (**locale_t**)0.

70527 **EXAMPLES**

70528 None.

70529 **APPLICATION USAGE**

70530 Unlike the *setlocale*( ) function, the *uselocale*( ) function does not allow replacing some locale
70531 categories only. Applications that need to install a locale which differs only in a few categories
70532 must use *newlocale*( ) to change a locale object equivalent to the currently used locale and install
70533 it.

70534 **RATIONALE**

70535 None.

70536 **FUTURE DIRECTIONS**

70537 None.

CHANGE HISTORY

First released in Issue 7.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0700 [290] and XSH/TC1-2008/0701 [334] are applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0382 [582] is applied.

NAME

utime ‡'set file access and modification times

SYNOPSIS

OB
```
#include <utime.h>

int utime(const char *path, const struct utimbuf *times);
```

DESCRIPTION

The *utime*( ) function shall set the access and modification times of the file named by the *path* argument.

If *times* is a null pointer, the access and modification times of the file shall be set to the current time. The effective user ID of the process shall match the owner of the file, or the process has write permission to the file or has appropriate privileges, to use *utime*( ) in this manner.

If *times* is not a null pointer, *times* shall be interpreted as a pointer to a **utimbuf** structure and the access and modification times shall be set to the values contained in the designated structure. Only a process with the effective user ID equal to the user ID of the file or a process with appropriate privileges may use *utime*( ) this way.

The **utimbuf** structure is defined in the **<utime.h>** header. The times in the structure **utimbuf** are measured in seconds since the Epoch.

Upon successful completion, the *utime*( ) function shall mark the last file status change timestamp for update; see **<sys/stat.h>**.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* shall be set to indicate the error, and the file times shall not be affected.

ERRORS

The *utime*( ) function shall fail if:

[EACCES] Search permission is denied by a component of the path prefix; or the *times* argument is a null pointer and the effective user ID of the process does not match the owner of the file, the process does not have write permission for the file, and the process does not have appropriate privileges.

[ELOOP] A loop exists in symbolic links encountered during resolution of the *path* argument.

[ENAMETOOLONG] The length of a component of a pathname is longer than {NAME_MAX}.

[ENOENT] A component of *path* does not name an existing file or *path* is an empty string.

[ENOTDIR] A component of the path prefix names an existing file that is neither a directory nor a symbolic link to a directory, or the *path* argument contains at least one non-<slash> character and ends with one or more trailing <slash> characters and the last pathname component names an existing file that is neither a directory nor a symbolic link to a directory.

[EPERM] The *times* argument is not a null pointer and the effective user ID of the calling process does not match the owner of the file and the calling process does not have appropriate privileges.

70587 [EROFS] The file system containing the file is read-only.

70588 The *utime*( ) function may fail if:

70589 [ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during
70590 resolution of the *path* argument.

70591 [ENAMETOOLONG]
70592 The length of a pathname exceeds {PATH_MAX}, or pathname resolution of a
70593 symbolic link produced an intermediate result with a length that exceeds
70594 {PATH_MAX}.

70595 **EXAMPLES**

70596 None.

70597 **APPLICATION USAGE**

70598 Since the **utimbuf** structure only contains **time_t** variables and is not accurate to fractions of a
70599 second, applications should use the *utimensat*( ) function instead of the obsolescent *utime*( )
70600 function.

70601 **RATIONALE**

70602 The *actime* structure member must be present so that an application may set it, even though an
70603 implementation may ignore it and not change the last data access timestamp on the file. If an
70604 application intends to leave one of the times of a file unchanged while changing the other, it
70605 should use *stat*( ) or *fstat*( ) to retrieve the file's *st_atim* and *st_mtim* parameters, set *actime* and
70606 *modtime* in the buffer, and change one of them before making the *utime*( ) call.

70607 **FUTURE DIRECTIONS**

70608 The *utime*( ) function may be removed in a future version.

70609 **SEE ALSO**

70610 *fstat*( ), *fstatat*( ), *futimens*( )

70611 XBD **<sys/stat.h>**, **<utime.h>**

70612 **CHANGE HISTORY**

70613 First released in Issue 1. Derived from Issue 1 of the SVID.

70614 **Issue 6**

70615 The following new requirements on POSIX implementations derive from alignment with the
70616 Single UNIX Specification:

70617 The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was
70618 required for conforming implementations of previous POSIX specifications, it was not
70619 required for UNIX applications.

70620 The [ELOOP] mandatory error condition is added.

70621 A second [ENAMETOOLONG] is added as an optional error condition.

70622 The following changes were made to align with the IEEE P1003.1a draft standard:

70623 The [ELOOP] optional error condition is added.

70624 The normative text is updated to avoid use of the term ``must'' for application requirements.

70625 **Issue 7**

70626 Austin Group Interpretation 1003.1-2001 #143 is applied.

70627 The *utime*( ) function is marked obsolescent.

70628 Changes are made related to support for finegrained timestamps.

70629 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0702 [324] is applied.

70630 **NAME**

70631 utimensat, utimes ‡'set file access and modification times

70632 **SYNOPSIS**

70633
```
#include <sys/stat.h>
```

70634
```
int utimensat(int fd, const char *path, const struct timespec times[2],
```

70635
```
    int flag);
```

70636 XSI
```
#include <sys/time.h>
```

70637
```
int utimes(const char *path, const struct timeval times[2]);
```

NAME

vdprintf, vfprintf, vprintf, vsnprintf, vsprintf ‡'format output of a stdarg argument list

SYNOPSIS

```
#include <stdarg.h>
#include <stdio.h>

CX  int vdprintf(int fildes, const char *restrict format, va_list ap);
    int vfprintf(FILE *restrict stream, const char *restrict format,
        va_list ap);
    int vprintf(const char *restrict format, va_list ap);
    int vsnprintf(char *restrict s, size_t n, const char *restrict format,
        va_list ap);
    int vsprintf(char *restrict s, const char *restrict format, va_list ap);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *vdprintf*( ), *vfprintf*( ), *vprintf*( ), *vsnprintf*( ), and *vsprintf*( ) functions shall be equivalent to the CX *dprintf*( ), *fprintf*( ), *printf*( ), *snprintf*( ), and *sprintf*( ) functions respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by **<stdarg.h>**.

These functions shall not invoke the *va_end* macro. As these functions invoke the *va_arg* macro, the value of *ap* after the return is unspecified.

RETURN VALUE

Refer to *fprintf*( ).

ERRORS

Refer to *fprintf*( ).

EXAMPLES

None.

APPLICATION USAGE

Applications using these functions should call *va_end*(*ap*) afterwards to clean up.

RATIONALE

int vwscanf(const wchar_t *restrict format, va_list arg);
```

DESCRIPTION

Refer to *vfwscanf( )*.

NAME

wait, waitpid — wait for a child process to stop or terminate

SYNOPSIS

```
#include <sys/wait.h>

pid_t wait(int *stat_loc);
pid_t waitpid(pid_t pid, int *stat_loc, int options);
```

DESCRIPTION

The *wait*( ) and *waitpid*( ) functions shall obtain status information (see Section 2.13, on page 548) pertaining to one of the caller's child processes. The *wait*( ) function obtains status information for process termination from any child process. The *waitpid*( ) function obtains status information for process termination, and optionally process stop and/or continue, from a specified subset of the child processes.

The *wait*( ) function shall cause the calling thread to become blocked until status information generated by child process termination is made available to the thread, or until delivery of a signal whose action is either to execute a signal-catching function or to terminate the process, or an error occurs. If termination status information is available prior to the call to *wait*( ), return shall be immediate. If termination status information is available for two or more child processes, the order in which their status is reported is unspecified.

As described in Section 2.13 (on page 548), the *wait*( ) and *waitpid*( ) functions consume the status information they obtain.

The behavior when multiple threads are blocked in *wait*( ), *waitid*( ), or *waitpid*( ) is described in Section 2.13 (on page 548).

The *waitpid*( ) function shall be equivalent to *wait*( ) if the *pid* argument is (**pid_t**)–1 and the *options* argument is 0. Otherwise, its behavior shall be modified by the values of the *pid* and *options* arguments.

The *pid* argument specifies a set of child processes for which *status* is requested. The *waitpid*( ) function shall only return the status of a child process from this set:

If *pid* is equal to (**pid_t**)–1, *status* is requested for any child process. In this respect, *waitpid*( ) is then equivalent to *wait*( ).

If *pid* is greater than 0, it specifies the process ID of a single child process for which *status* is requested.

If *pid* is 0, *status* is requested for any child process whose process group ID is equal to that of the calling process.

If *pid* is less than (**pid_t**)–1, *status* is requested for any child process whose process group ID is equal to the absolute value of *pid*.

The *options* argument is constructed from the bitwise-inclusive OR of zero or more of the following flags, defined in the **<sys/wait.h>** header:

XSI

WCONTINUED The *waitpid*( ) function shall report the status of any continued child process specified by *pid* whose status has not been reported since it continued from a job control stop.

WNOHANG The *waitpid*( ) function shall not suspend execution of the calling thread if *status* is not immediately available for one of the child processes specified by *pid*.

WUNTRACED The status of any child processes specified by *pid* that are stopped, and whose status has not yet been reported since they stopped, shall also be reported to the requesting process.

If *wait*( ) or *waitpid*( ) return because the status of a child process is available, these functions shall return a value equal to the process ID of the child process. In this case, if the value of the argument *stat_loc* is not a null pointer, information shall be stored in the location pointed to by *stat_loc*. The value stored at the location pointed to by *stat_loc* shall be 0 if and only if the status returned is from a terminated child process that terminated by one of the following means:

1. The process returned 0 from *main*( ).
2. The process called *_exit*( ) or *exit*( ) with a *status* argument of 0.
3. The process was terminated because the last thread in the process terminated.

Regardless of its value, this information may be interpreted using the following macros, which are defined in **<sys/wait.h>** and evaluate to integral expressions; the *stat_val* argument is the integer value pointed to by *stat_loc*.

WIFEXITED(*stat_val*)
Evaluates to a non-zero value if *status* was returned for a child process that terminated normally.

WEXITSTATUS(*stat_val*)
If the value of WIFEXITED(*stat_val*) is non-zero, this macro evaluates to the low-order 8 bits of the *status* argument that the child process passed to *_exit*( ) or *exit*( ), or the value the child process returned from *main*( ).

WIFSIGNALED(*stat_val*)
Evaluates to a non-zero value if *status* was returned for a child process that terminated due to the receipt of a signal that was not caught (see **<signal.h>**).

WTERMSIG(*stat_val*)
If the value of WIFSIGNALED(*stat_val*) is non-zero, this macro evaluates to the number of the signal that caused the termination of the child process.

WIFSTOPPED(*stat_val*)
Evaluates to a non-zero value if *status* was returned for a child process that is currently stopped.

WSTOPSIG(*stat_val*)
If the value of WIFSTOPPED(*stat_val*) is non-zero, this macro evaluates to the number of the signal that caused the child process to stop.

XSI WIFCONTINUED(*stat_val*)
Evaluates to a non-zero value if *status* was returned for a child process that has continued from a job control stop.

SPN It is unspecified whether the *status* value returned by calls to *wait*( ) or *waitpid*( ) for processes created by *posix_spawn*( ) or *posix_spawnp*( ) can indicate a WIFSTOPPED(*stat_val*) before subsequent calls to *wait*( ) or *waitpid*( ) indicate WIFEXITED(*stat_val*) as the result of an error detected before the new process image starts executing.

It is unspecified whether the *status* value returned by calls to *wait*( ) or *waitpid*( ) for processes created by *posix_spawn*( ) or *posix_spawnp*( ) can indicate a WIFSIGNALED(*stat_val*) if a signal is sent to the parent's process group after *posix_spawn*( ) or *posix_spawnp*( ) is called.

If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that specified the

XSI WUNTRACED flag and did not specify the WCONTINUED flag, exactly one of the macros WIFEXITED(*stat_loc), WIFSIGNALED(*stat_loc), and WIFSTOPPED(*stat_loc) shall evaluate to a non-zero value.

XSI If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that specified the WUNTRACED and WCONTINUED flags, exactly one of the macros WIFEXITED(*stat_loc), WIFSIGNALED(*stat_loc), WIFSTOPPED(*stat_loc), and WIFCONTINUED(*stat_loc) shall evaluate to a non-zero value.

If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that did not specify the XSI WUNTRACED or WCONTINUED flags, or by a call to the *wait*( ) function, exactly one of the macros WIFEXITED(*stat_loc) and WIFSIGNALED(*stat_loc) shall evaluate to a non-zero value.

XSI If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that did not specify the WUNTRACED flag and specified the WCONTINUED flag, exactly one of the macros WIFEXITED(*stat_loc), WIFSIGNALED(*stat_loc), and WIFCONTINUED(*stat_loc) shall evaluate to a non-zero value.

If _POSIX_REALTIME_SIGNALS is defined, and the implementation queues the SIGCHLD signal, then if *wait*( ) or *waitpid*( ) returns because the status of a child process is available, any pending SIGCHLD signal associated with the process ID of the child process shall be discarded. Any other pending SIGCHLD signals shall remain pending.

Otherwise, if SIGCHLD is blocked, if *wait*( ) or *waitpid*( ) return because the status of a child process is available, any pending SIGCHLD signal shall be cleared unless the status of another child process is available.

For all other conditions, it is unspecified whether child *status* will be available when a SIGCHLD signal is delivered.

There may be additional implementation-defined circumstances under which *wait*( ) or *waitpid*( ) report *status*. This shall not occur unless the calling process or one of its child processes explicitly makes use of a non-standard extension. In these cases the interpretation of the reported *status* is implementation-defined.

If a parent process terminates without waiting for all of its child processes to terminate, the remaining child processes shall be assigned a new parent process ID corresponding to an implementation-defined system process.

RETURN VALUE

If *wait*( ) or *waitpid*( ) returns because the status of a child process is available, these functions shall return a value equal to the process ID of the child process for which *status* is reported. If *wait*( ) or *waitpid*( ) returns due to the delivery of a signal to the calling process, −1 shall be returned and *errno* set to [EINTR]. If *waitpid*( ) was invoked with WNOHANG set in *options*, it has at least one child process specified by *pid* for which *status* is not available, and *status* is not available for any process specified by *pid*, 0 is returned. Otherwise, −1 shall be returned, and *errno* set to indicate the error.

ERRORS

The *wait*( ) function shall fail if:

[ECHILD] The calling process has no existing unwaited-for child processes.

[EINTR] The function was interrupted by a signal. The value of the location pointed to by *stat_loc* is undefined.

The *waitpid*( ) function shall fail if:

71023 [ECHILD] The process specified by *pid* does not exist or is not a child of the calling
71024 process, or the process group specified by *pid* does not exist or does not have
71025 any member process that is a child of the calling process.

71026 [EINTR] The function was interrupted by a signal. The value of the location pointed to
71027 by *stat_loc* is undefined.

71028 [EINVAL] The *options* argument is not valid.

71029 **EXAMPLES**

71030 **Waiting for a Child Process and then Checking its Status**

71031 The following example demonstrates the use of *waitpid*(), *fork*(), and the macros used to
71032 interpret the status value returned by *waitpid*() (and *wait*()). The code segment creates a child
71033 process which does some unspecified work. Meanwhile the parent loops performing calls to
71034 *waitpid*() to monitor the status of the child. The loop terminates when child termination is
71035 detected.

```
71036 #include <stdio.h>
71037 #include <stdlib.h>
71038 #include <unistd.h>
71039 #include <sys/wait.h>
71040 ...

71041 pid_t child_pid, wpid;
71042 int status;

71043 child_pid = fork();
71044 if (child_pid == -1) {      /* fork() failed */
71045     perror("fork");
71046     exit(EXIT_FAILURE);
71047 }

71048 if (child_pid == 0) {       /* This is the child */
71049     /* Child does some work and then terminates */
71050     ...

71051 } else {                    /* This is the parent */
71052     do {
71053         wpid = waitpid(child_pid, &status, WUNTRACED
71054 #ifdef WCONTINUED       /* Not all implementations support this */
71055         | WCONTINUED
71056 #endif
71057         );
71058         if (wpid == -1) {
71059             perror("waitpid");
71060             exit(EXIT_FAILURE);
71061         }

71062         if (WIFEXITED(status)) {
71063             printf("child exited, status=%d\n", WEXITSTATUS(status));

71064         } else if (WIFSIGNALED(status)) {
71065             printf("child killed (signal %d)\n", WTERMSIG(status));

71066         } else if (WIFSTOPPED(status)) {
71067             printf("child stopped (signal %d)\n", WSTOPSIG(status));
```

```
#ifdef WIFCONTINUED     /* Not all implementations support this */
        } else if (WIFCONTINUED(status)) {
            printf("child continued\n");
#endif
        } else {    /* Non-standard case -- may never happen */
            printf("Unexpected status (0x%x)\n", status);
        }
    } while (!WIFEXITED(status) && !WIFSIGNALED(status));
}
```

Waiting for a Child Process in a Signal Handler for SIGCHLD

The following example demonstrates how to use *waitpid*() in a signal handler for SIGCHLD without passing –1 as the *pid* argument. (See the APPLICATION USAGE section below for the reasons why passing a *pid* of –1 is not recommended.) The method used here relies on the standard behavior of *waitpid*() when SIGCHLD is blocked. On historical non-conforming systems, the status of some child processes might not be reported.

```
#include <stdlib.h>
#include <stdio.h>
#include <signal.h>
#include <sys/types.h>
#include <sys/wait.h>
#include <unistd.h>

#define CHILDREN 10

static void
handle_sigchld(int signum, siginfo_t *sinfo, void *unused)
{
    int sav_errno = errno;
    int status;

    /*
     * Obtain status information for the child which
     * caused the SIGCHLD signal and write its exit code
     * to stdout.
    */
    if (sinfo->si_code != CLD_EXITED)
    {
        static char msg[] = "wrong si_code\n";
        write(2, msg, sizeof msg - 1);
    }
    else if (waitpid(sinfo->si_pid, &status, 0) == -1)
    {
        static char msg[] = "waitpid() failed\n";
        write(2, msg, sizeof msg - 1);
    }
    else if (!WIFEXITED(status))
    {
        static char msg[] = "WIFEXITED was false\n";
        write(2, msg, sizeof msg - 1);
    }
    else
```

```
71116            {
71117                int code = WEXITSTATUS(status);
71118                char buf[2];
71119                buf[0] = '0' + code;
71120                buf[1] = '\n';
71121                write(1, buf, 2);
71122            }
71123            errno = sav_errno;
71124        }

71125        int
71126        main(void)
71127        {
71128            int i;
71129            pid_t pid;
71130            struct sigaction sa;

71131            sa.sa_flags = SA_SIGINFO;
71132            sa.sa_sigaction = handle_sigchld;
71133            sigemptyset(&sa.sa_mask);
71134            if (sigaction(SIGCHLD, &sa, NULL) == -1)
71135            {
71136                perror("sigaction");
71137                exit(EXIT_FAILURE);
71138            }

71139            for (i = 0; i < CHILDREN; i++)
71140            {
71141                switch (pid = fork())
71142                {
71143                case -1:
71144                    perror("fork");
71145                    exit(EXIT_FAILURE);
71146                case 0:
71147                    sleep(2);
71148                    _exit(i);
71149                }
71150            }

71151            /* Wait for all the SIGCHLD signals, then terminate on SIGALRM */
71152            alarm(3);
71153            for (;;)
71154                pause();

71155            return 0; /* NOTREACHED */
71156        }
```

APPLICATION USAGE

71157 71158 71159 71160 71161 71162 71163

Calls to *wait*( ) will collect information about any child process. This may result in interactions with other interfaces that may be waiting for their own children (such as by use of *system*( )). For this and other reasons it is recommended that portable applications not use *wait*( ), but instead use *waitpid*( ). For these same reasons, the use of *waitpid*( ) with a *pid* argument of –1, and the use of *waitid*( ) with the *idtype* argument set to P_ALL, are also not recommended for portable applications.

XSI As specified in Consequences of Process Termination (on page 553), if the calling process has SA_NOCLDWAIT set or has SIGCHLD set to SIG_IGN, then the termination of a child process will not cause status information to become available to a thread blocked in *wait*( ), *waitid*( ), or *waitpid*( ). Thus, a thread blocked in one of the wait functions will remain blocked unless some other condition causes the thread to resume execution (such as an [ECHILD] failure due to no remaining children in the set of waited-for children).

RATIONALE

A call to the *wait*( ) or *waitpid*( ) function only returns *status* on an immediate child process of the calling process; that is, a child that was produced by a single *fork*( ) call (perhaps followed by an *exec* or other function calls) from the parent. If a child produces grandchildren by further use of *fork*( ), none of those grandchildren nor any of their descendants affect the behavior of a *wait*( ) from the original parent process. Nothing in this volume of POSIX.1-2017 prevents an implementation from providing extensions that permit a process to get *status* from a grandchild or any other process, but a process that does not use such extensions must be guaranteed to see *status* from only its direct children.

The *waitpid*( ) function is provided for three reasons:

1. To support job control
2. To permit a non-blocking version of the *wait*( ) function
3. To permit a library routine, such as *system*( ) or *pclose*( ), to wait for its children without interfering with other terminated children for which the process has not waited

The first two of these facilities are based on the *wait3*( ) function provided by 4.3 BSD. The function uses the *options* argument, which is equivalent to an argument to *wait3*( ). The WUNTRACED flag is used only in conjunction with job control on systems supporting job control. Its name comes from 4.3 BSD and refers to the fact that there are two types of stopped processes in that implementation: processes being traced via the *ptrace*( ) debugging facility and (untraced) processes stopped by job control signals. Since *ptrace*( ) is not part of this volume of POSIX.1-2017, only the second type is relevant. The name WUNTRACED was retained because its usage is the same, even though the name is not intuitively meaningful in this context.

The third reason for the *waitpid*( ) function is to permit independent sections of a process to spawn and wait for children without interfering with each other. For example, the following problem occurs in developing a portable shell, or command interpreter:

```
stream = popen("/bin/true");
(void) system("sleep 100");
(void) pclose(stream);
```

On all historical implementations, the final *pclose*( ) fails to reap the *wait*( ) *status* of the *popen*( ).

The status values are retrieved by macros, rather than given as specific bit encodings as they are in most historical implementations (and thus expected by existing programs). This was necessary to eliminate a limitation on the number of signals an implementation can support that was inherent in the traditional encodings. This volume of POSIX.1-2017 does require that a *status* value of zero corresponds to a process calling *_exit*(0), as this is the most common encoding expected by existing programs. Some of the macro names were adopted from 4.3 BSD.

These macros syntactically operate on an arbitrary integer value. The behavior is undefined unless that value is one stored by a successful call to *wait*( ) or *waitpid*( ) in the location pointed to by the *stat_loc* argument. An early proposal attempted to make this clearer by specifying each argument as **stat_loc* rather than *stat_val*. However, that did not follow the conventions of other specifications in this volume of POSIX.1-2017 or traditional usage. It also could have implied

that the argument to the macro must literally be *stat_loc*; in fact, that value can be stored or passed as an argument to other functions before being interpreted by these macros.

The extension that affects *wait*( ) and *waitpid*( ) and is common in historical implementations is the *ptrace*( ) function. It is called by a child process and causes that child to stop and return a *status* that appears identical to the *status* indicated by WIFSTOPPED. The *status* of *ptrace*( ) children is traditionally returned regardless of the WUNTRACED flag (or by the *wait*( ) function). Most applications do not need to concern themselves with such extensions because they have control over what extensions they or their children use. However, applications, such as command interpreters, that invoke arbitrary processes may see this behavior when those arbitrary processes misuse such extensions.

Implementations that support **core** file creation or other implementation-defined actions on termination of some processes traditionally provide a bit in the *status* returned by *wait*( ) to indicate that such actions have occurred.

Allowing the *wait*( ) family of functions to discard a pending SIGCHLD signal that is associated with a successfully waited-for child process puts them into the *sigwait*( ) and *sigwaitinfo*( ) category with respect to SIGCHLD.

This definition allows implementations to treat a pending SIGCHLD signal as accepted by the process in *wait*( ), with the same meaning of ``accepted'' as when that word is applied to the *sigwait*( ) family of functions.

Allowing the *wait*( ) family of functions to behave this way permits an implementation to be able to deal precisely with SIGCHLD signals.

In particular, an implementation that does accept (discard) the SIGCHLD signal can make the following guarantees regardless of the queuing depth of signals in general (the list of waitable children can hold the SIGCHLD queue):

1. If a SIGCHLD signal handler is established via *sigaction*( ) without the SA_RESETHAND flag, SIGCHLD signals can be accurately counted; that is, exactly one SIGCHLD signal will be delivered to or accepted by the process for every child process that terminates.
2. A single *wait*( ) issued from a SIGCHLD signal handler can be guaranteed to return immediately with status information for a child process.
3. When SA_SIGINFO is requested, the SIGCHLD signal handler can be guaranteed to receive a non-null pointer to a **siginfo_t** structure that describes a child process for which a wait via *waitpid*( ) or *waitid*( ) will not block or fail.
4. The *system*( ) function will not cause the SIGCHLD handler of a process to be called as a result of the *fork*( )/*exec* executed within *system*( ) because *system*( ) will accept the SIGCHLD signal when it performs a *waitpid*( ) for its child process. This is a desirable behavior of *system*( ) so that it can be used in a library without causing side-effects to the application linked with the library.

An implementation that does not permit the *wait*( ) family of functions to accept (discard) a pending SIGCHLD signal associated with a successfully waited-for child, cannot make the guarantees described above for the following reasons:

Guarantee #1

Although it might be assumed that reliable queuing of all SIGCHLD signals generated by the system can make this guarantee, the counter-example is the case of a process that blocks SIGCHLD and performs an indefinite loop of *fork*( )/*wait*( ) operations. If the implementation supports queued signals, then eventually the system will run out of memory for the queue. The guarantee cannot be made because there must be some limit to

71256 the depth of queuing.

71257 Guarantees #2 and #3

71258 These cannot be guaranteed unless the *wait*( ) family of functions accepts the SIGCHLD
71259 signal. Otherwise, a *fork*( )/*wait*( ) executed while SIGCHLD is blocked (as in the *system*( )
71260 function) will result in an invocation of the handler when SIGCHLD is unblocked, after the
71261 process has disappeared.

71262 Guarantee #4

71263 Although possible to make this guarantee, *system*( ) would have to set the SIGCHLD
71264 handler to SIG_DFL so that the SIGCHLD signal generated by its *fork*( ) would be discarded
71265 (the SIGCHLD default action is to be ignored), then restore it to its previous setting. This
71266 would have the undesirable side-effect of discarding all SIGCHLD signals pending to the
71267 process.

71268 **FUTURE DIRECTIONS**

71269 None.

71270 **SEE ALSO**

71273 **CHANGE HISTORY**

71274 First released in Issue 1. Derived from Issue 1 of the SVID.

71275 **Issue 5**

71276 The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

71277 **Issue 6**

71278 The following new requirements on POSIX implementations derive from alignment with the
71279 Single UNIX Specification:

71280 The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was
71281 required for conforming implementations of previous POSIX specifications, it was not
71282 required for UNIX applications.

71283 The following changes were made to align with the IEEE P1003.1a draft standard:

71284 The processing of the SIGCHLD signal and the [ECHILD] error is clarified.

71285 The semantics of WIFSTOPPED(*stat_val*), WIFEXITED(*stat_val*), and WIFSIGNALED(*stat_val*)
71286 are defined with respect to *posix_spawn*( ) or *posix_spawnp*( ) for alignment with IEEE Std
71287 1003.1d-1999.

71288 The DESCRIPTION is updated for alignment with the ISO/IEC 9899: 1999 standard.

71289 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/145 is applied, adding the example to the
71290 EXAMPLES section.

71291 **Issue 7**

71292 SD5-XSH-ERN-202 is applied.

71293 APPLICATION USAGE is added, recommending that the *wait*( ) function not be used.

71294 An additional example for *waitpid*( ) is added.

71295 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0707 [421], XSH/TC1-2008/0708 [166],
71296 XSH/TC1-2008/0709 [166], and XSH/TC1-2008/0710 [69] are applied.

71297 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0384 [690], XSH/TC2-2008/0385 [691],
71298 and XSH/TC2-2008/0386 [690] are applied.

71299 **NAME**

71300 waitid — wait for a child process to change state

71301 **SYNOPSIS**

71302 ```
#include <sys/wait.h>
```

71303 ```
int waitid(idtype_t idtype, id_t id, siginfo_t *infop, int options);
```

71304 **DESCRIPTION**

71305 The *waitid*( ) function shall obtain status information (see Section 2.13, on page 548) pertaining to
71306 termination, stop, and/or continue events in one of the caller's child processes.

71307 The *waitid*( ) function shall cause the calling thread to become blocked until an error occurs or
71308 status information becomes available to the calling thread that satisfies all of the following
71309 properties (``matching status information''):

71310 The status information is from one of the child processes in the set of child processes
71311 specified by the *idtype* and *id* arguments.

71312 The state change in the status information matches one of the state change flags set in the
71313 *options* argument.

71314 If matching status information is available prior to the call to *waitid*( ), return shall be immediate.
71315 If matching status information is available for two or more child processes, the order in which
71316 their status is reported is unspecified.

71317 As described in Section 2.13 (on page 548), the *waitid*( ) function consumes the status information
71318 it obtains unless the WNOWAIT flag is set in the *options* argument.

71319 The behavior when multiple threads are blocked in *wait*( ), *waitid*( ), or *waitpid*( ) is described in
71320 Section 2.13 (on page 548).

71321 The *waitid*( ) function shall record the obtained status information in the structure pointed to by
71322 *infop*. The fields of the structure pointed to by *infop* shall be filled in as described under ``Pointer
71323 to a Function'' in Section 2.4.3 (on page 490).

71324 The *idtype* and *id* arguments are used to specify which children *waitid*( ) waits for.

71325 If *idtype* is P_PID, *waitid*( ) shall wait for the child with a process ID equal to (**pid_t**)*id*.

71326 If *idtype* is P_PGID, *waitid*( ) shall wait for any child with a process group ID equal to (**pid_t**)*id*.

71327 If *idtype* is P_ALL, *waitid*( ) shall wait for any children and *id* is ignored.

71328 The *options* argument is used to specify which state changes *waitid*( ) shall wait for. It is formed
71329 by OR'ing together the following flags:

71330 WCONTINUED Status shall be returned for any continued child process whose status either
71331 has not been reported since it continued from a job control stop or has been
71332 reported only by calls to *waitid*( ) with the WNOWAIT flag set.

71333 WEXITED Wait for processes that have exited.

71334 WNOHANG Do not hang if no status is available; return immediately.

71335 WNOWAIT Keep the process whose status is returned in *infop* in a waitable state. This
71336 shall not affect the state of the process; the process may be waited for again
71337 after this call completes.

71338 WSTOPPED Status shall be returned for any child that has stopped upon receipt of a signal,
71339 and whose status either has not been reported since it stopped or has been
71340 reported only by calls to *waitid*( ) with the WNOWAIT flag set.

Applications shall specify at least one of the flags WEXITED, WSTOPPED, or WCONTINUED to be OR'ed in with the *options* argument.

The application shall ensure that the *infop* argument points to a **siginfo_t** structure. If *waitid*( ) returns because a child process was found that satisfied the conditions indicated by the arguments *idtype* and *options*, then the structure pointed to by *infop* shall be filled in by the system with the status of the process; the *si_signo* member shall be set equal to SIGCHLD. If *waitid*( ) returns because WNOHANG was specified and status is not available for any process specified by *idtype* and *id*, then the *si_signo* and *si_pid* members of the structure pointed to by *infop* shall be set to zero and the values of other members of the structure are unspecified.

RETURN VALUE

If WNOHANG was specified and status is not available for any process specified by *idtype* and *id*, 0 shall be returned. If *waitid*( ) returns due to the change of state of one of its children, 0 shall be returned. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *waitid*( ) function shall fail if:

[ECHILD] The calling process has no existing unwaited-for child processes.

[EINTR] The *waitid*( ) function was interrupted by a signal.

[EINVAL] An invalid value was specified for *options*, or *idtype* and *id* specify an invalid set of processes.

EXAMPLES

None.

APPLICATION USAGE

Calls to *waitid*( ) with *idtype* equal to P_ALL will collect information about any child process. This may result in interactions with other interfaces that may be waiting for their own children (such as by use of *system*( )). For this reason it is recommended that portable applications not use *waitid*( ) with idtype of P_ALL. See also APPLICATION USAGE for *wait*( ).

XSI As specified in Consequences of Process Termination (on page 553), if the calling process has SA_NOCLDWAIT set or has SIGCHLD set to SIG_IGN, then the termination of a child process will not cause status information to become available to a thread blocked in *wait*( ), *waitid*( ), or *waitpid*( ). Thus, a thread blocked in one of the wait functions will remain blocked unless some other condition causes the thread to resume execution (such as an [ECHILD] failure due to no remaining children in the set of waited-for children).

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD **<signal.h>**, **<sys/wait.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The normative text is updated to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #060 is applied, updating the DESCRIPTION.

The *waitid*( ) function is moved from the XSI option to the Base.

APPLICATION USAGE is added, recommending that the *waitid*( ) function not be used with *idtype* equal to P_ALL.

The description of the WNOHANG flag is updated.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0711 [154], XSH/TC1-2008/0712 [154], and XSH/TC1-2008/0713 [153] are applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0387 [690] is applied.

71396 **NAME**

71397 waitpid — wait for a child process to stop or terminate

71398 **SYNOPSIS**

71399 `#include <sys/wait.h>`

71400 `pid_t waitpid(pid_t` *`pid`*`, int *`*`stat_loc`*`, int` *`options`*`);`

71401 **DESCRIPTION**

71402 Refer to *wait( )*.

71403 **NAME**

71404 wcpcpy — copy a wide-character string, returning a pointer to its end

71405 **SYNOPSIS**

71406 CX
```
#include <wchar.h>

wchar_t *wcpcpy(wchar_t *restrict ws1, const wchar_t *restrict ws2);
```
71407

71408 **DESCRIPTION**

71409 Refer to *wcscpy( )*.

NAME

wcpncpy — copy a fixed-size wide-character string, returning a pointer to its end

SYNOPSIS

CX
```
#include <wchar.h>

wchar_t *wcpncpy(wchar_t restrict *ws1, const wchar_t *restrict ws2,
    size_t n);
```

DESCRIPTION

Refer to *wcsncpy( )*.

NAME

wcrtomb — convert a wide-character code to a character (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t wcrtomb(char *restrict s, wchar_t wc, mbstate_t *restrict ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

If *s* is a null pointer, the *wcrtomb*( ) function shall be equivalent to the call:

```
wcrtomb(buf, L'\0', ps)
```

where *buf* is an internal buffer.

If *s* is not a null pointer, the *wcrtomb*( ) function shall determine the number of bytes needed to represent the character that corresponds to the wide character given by *wc* (including any shift sequences), and store the resulting bytes in the array whose first element is pointed to by *s*. At most {MB_CUR_MAX} bytes are stored. If *wc* is a null wide character, a null byte shall be stored, preceded by any shift sequence needed to restore the initial shift state. The resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *wcrtomb*( ) function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence. The implementation shall behave as if no function defined in this volume of POSIX.1-2017 calls *wcrtomb*( ).

CX The *wcrtomb*( ) function need not be thread-safe if called with a NULL *ps* argument.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

The *wcrtomb*( ) function shall not change the setting of *errno* if successful.

RETURN VALUE

The *wcrtomb*( ) function shall return the number of bytes stored in the array object (including any shift sequences). When *wc* is not a valid wide character, an encoding error shall occur. In this case, the function shall store the value of the macro [EILSEQ] in *errno* and shall return (**size_t**)–1; the conversion state shall be undefined.

ERRORS

The *wcrtomb*( ) function shall fail if:

[EILSEQ] An invalid wide-character code is detected.

The *wcrtomb*( ) function may fail if:

CX [EINVAL] *ps* points to an object that contains an invalid conversion state.

71454 **EXAMPLES**

71455 None.

71456 **APPLICATION USAGE**

71457 None.

71458 **RATIONALE**

71459 None.

71460 **FUTURE DIRECTIONS**

71461 None.

71462 **SEE ALSO**

71463 *mbsinit*( ), *wcsrtombs*( )

71464 XBD **<wchar.h>**

71465 **CHANGE HISTORY**

71466 First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995
71467 (E).

71468 **Issue 6**

71469 In the DESCRIPTION, a note on using this function in a threaded application is added.

71470 Extensions beyond the ISO C standard are marked.

71471 The normative text is updated to avoid use of the term ``must'' for application requirements.

71472 The *wcrtomb*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

71473 **Issue 7**

71474 Austin Group Interpretation 1003.1-2001 #148 is applied, clarifying that the *wcrtomb*( ) function
71475 need not be thread-safe if called with a NULL *ps* argument.

71476 Austin Group Interpretation 1003.1-2001 #170 is applied.

71477 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0714 [88] and XSH/TC1-2008/0715
71478 [105] are applied.

NAME

wcscasecmp, wcscasecmp_l, wcsncasecmp, wcsncasecmp_l ‡' case-insensitive wide-character string comparison

SYNOPSIS

CX
```
#include <wchar.h>

int wcscasecmp(const wchar_t *ws1, const wchar_t *ws2);
int wcscasecmp_l(const wchar_t *ws1, const wchar_t *ws2,
    locale_t locale);
int wcsncasecmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);
int wcsncasecmp_l(const wchar_t *ws1, const wchar_t *ws2,
    size_t n, locale_t locale);
```

DESCRIPTION

The *wcscasecmp*( ) and *wcsncasecmp*( ) functions are the wide-character equivalent of the *strcasecmp*( ) and *strncasecmp*( ) functions, respectively.

The *wcscasecmp*( ) and *wcscasecmp_l*( ) functions shall compare, while ignoring differences in case, the wide-character string pointed to by *ws1* to the wide-character string pointed to by *ws2*.

The *wcsncasecmp*( ) and *wcsncasecmp_l*( ) functions shall compare, while ignoring differences in case, not more than *n* wide-characters from the wide-character string pointed to by *ws1* to the wide-character string pointed to by *ws2*.

The *wcscasecmp*( ) and *wcsncasecmp*( ) functions use the current locale to determine the case of the wide characters.

The *wcscasecmp_l*( ) and *wcsncasecmp_l*( ) functions use the locale represented by *locale* to determine the case of the wide characters.

When the *LC_CTYPE* category of the locale being used is from the POSIX locale, these functions shall behave as if the wide-character strings had been converted to lowercase and then a comparison of wide-character codes performed. Otherwise, the results are unspecified.

The information for *wcscasecmp_l*( ) and *wcsncasecmp_l*( ) about the case of the characters comes from the locale represented by *locale*.

The behavior is undefined if the *locale* argument to *wcscasecmp_l*( ) or *wcsncasecmp_l*( ) is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

Upon completion, the *wcscasecmp*( ) and *wcscasecmp_l*( ) functions shall return an integer greater than, equal to, or less than 0 if the wide-character string pointed to by *ws1* is, ignoring case, greater than, equal to, or less than the wide-character string pointed to by *ws2*, respectively.

Upon completion, the *wcsncasecmp*( ) and *wcsncasecmp_l*( ) functions shall return an integer greater than, equal to, or less than 0 if the possibly null wide-character terminated string pointed to by *ws1* is, ignoring case, greater than, equal to, or less than the possibly null wide-character terminated string pointed to by *ws2*, respectively.

No return values are reserved to indicate an error.

ERRORS

No errors are defined.

71520 **EXAMPLES**

71521 None.

71522 **APPLICATION USAGE**

71523 None.

71524 **RATIONALE**

71525 None.

71526 **FUTURE DIRECTIONS**

71527 None.

71530 XBD **<wchar.h>**

71531 **CHANGE HISTORY**

71532 First released in Issue 7.

71533 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0716 [294], XSH/TC1-2008/0717 [283],
71534 and XSH/TC1-2008/0718 [283] are applied.

71535 **NAME**

71536 wcscat ‡'concatenate two wide-character strings

71537 **SYNOPSIS**

71538 `#include <wchar.h>`

71539 `wchar_t *wcscat(wchar_t *restrict ws1, const wchar_t *restrict ws2);`

71540 **DESCRIPTION**

71541 CX The functionality described on this reference page is aligned with the ISO C standard. Any
71542 conflict between the requirements described here and the ISO C standard is unintentional. This
71543 volume of POSIX.1-2017 defers to the ISO C standard.

71544 The *wcscat*( ) function shall append a copy of the wide-character string pointed to by *ws2*
71545 (including the terminating null wide-character code) to the end of the wide-character string
71546 pointed to by *ws1*. The initial wide-character code of *ws2* shall overwrite the null wide-character
71547 code at the end of *ws1*. If copying takes place between objects that overlap, the behavior is
71548 undefined.

71549 **RETURN VALUE**

71550 The *wcscat*( ) function shall return *ws1*; no return value is reserved to indicate an error.

71551 **ERRORS**

71552 No errors are defined.

71553 **EXAMPLES**

71554 None.

71555 **APPLICATION USAGE**

71556 None.

71557 **RATIONALE**

71558 None.

71559 **FUTURE DIRECTIONS**

71560 None.

71564 **CHANGE HISTORY**

71565 First released in Issue 4. Derived from the MSE working draft.

71566 **Issue 6**

71567 The Open Group Corrigendum U040/2 is applied. In the RETURN VALUE section, *s1* is
71568 changed to *ws1*.

71569 The *wcscat*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

NAME

wcschr ‡'wide-character string scanning operation

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcschr(const wchar_t *ws, wchar_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcschr*( ) function shall locate the first occurrence of *wc* in the wide-character string pointed to by *ws*. The application shall ensure that the value of *wc* is a character representable as a type **wchar_t** and a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string.

RETURN VALUE

Upon completion, *wcschr*( ) shall return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 6

The normative text is updated to avoid use of the term ``must'' for application requirements.

71603 **NAME**

71604 wcscmp ‡’compare two wide-character strings

71605 **SYNOPSIS**

71606 `#include <wchar.h>`

71607 `int wcscmp(const wchar_t *ws1, const wchar_t *ws2);`

71608 **DESCRIPTION**

71609 CX The functionality described on this reference page is aligned with the ISO C standard. Any
71610 conflict between the requirements described here and the ISO C standard is unintentional. This
71611 volume of POSIX.1-2017 defers to the ISO C standard.

71612 The *wcscmp*( ) function shall compare the wide-character string pointed to by *ws1* to the wide-
71613 character string pointed to by *ws2*.

71614 The sign of a non-zero return value shall be determined by the sign of the difference between the
71615 values of the first pair of wide-character codes that differ in the objects being compared.

71616 **RETURN VALUE**

71617 Upon completion, *wcscmp*( ) shall return an integer greater than, equal to, or less than 0, if the
71618 wide-character string pointed to by *ws1* is greater than, equal to, or less than the wide-character
71619 string pointed to by *ws2*, respectively.

71620 **ERRORS**

71621 No errors are defined.

71622 **EXAMPLES**

71623 None.

71624 **APPLICATION USAGE**

71625 None.

71626 **RATIONALE**

71627 None.

71628 **FUTURE DIRECTIONS**

71629 None.

71630 **SEE ALSO**

71631 *wcscasecmp*( ), *wcsncmp*( )

71632 XBD **<wchar.h>**

71633 **CHANGE HISTORY**

71634 First released in Issue 4. Derived from the MSE working draft.

71635 **NAME**

71636 wcscoll, wcscoll_l ‡'wide-character string comparison using collating information

71637 **SYNOPSIS**

71638
```
#include <wchar.h>
```

71639
```
int wcscoll(const wchar_t *ws1, const wchar_t *ws2);
```

71640 CX
```
int wcscoll_l(const wchar_t *ws1, const wchar_t *ws2,
    locale_t locale);
```

71641

71642 **DESCRIPTION**

71643 CX For *wcscoll*( ): The functionality described on this reference page is aligned with the ISO C
71644 standard. Any conflict between the requirements described here and the ISO C standard is
71645 unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

71646 CX The *wcscoll*( ) and *wcscoll_l*( ) functions shall compare the wide-character string pointed to by
71647 *ws1* to the wide-character string pointed to by *ws2*, both interpreted as appropriate to the
71648 CX *LC_COLLATE* category of the current locale, or the locale represented by *locale*, respectively.

71649 CX The *wcscoll*( ) and *wcscoll_l*( ) functions shall not change the setting of *errno* if successful.

71650 CX An application wishing to check for error situations should set *errno* to 0 before calling *wcscoll*( )
71651 or *wcscoll_l*( ). If *errno* is non-zero on return, an error has occurred.

71652 CX The behavior is undefined if the *locale* argument to *wcscoll_l*( ) is the special locale object
71653 LC_GLOBAL_LOCALE or is not a valid locale object handle.

71654 **RETURN VALUE**

71655 CX Upon successful completion, *wcscoll*( ) and *wcscoll_l*( ) shall return an integer greater than, equal
71656 to, or less than 0, according to whether the wide-character string pointed to by *ws1* is greater
71657 than, equal to, or less than the wide-character string pointed to by *ws2*, when both are
71658 CX interpreted as appropriate to the current locale, or to the locale represented by *locale*,
71659 CX respectively. On error, *wcscoll*( ) and *wcscoll_l*( ) shall set *errno*, but no return value is reserved
71660 to indicate an error.

71661 **ERRORS**

71662 These functions may fail if:

71663 CX [EINVAL] The *ws1* or *ws2* arguments contain wide-character codes outside the domain of
71664 the collating sequence.

71665 **EXAMPLES**

71666 None.

71667 **APPLICATION USAGE**

71668 The *wcsxfrm*( ) and *wcscmp*( ) functions should be used for sorting large lists.

71669 **RATIONALE**

71670 None.

71671 **FUTURE DIRECTIONS**

71672 None.

71673 **SEE ALSO**

71674 *wcscmp*( ), *wcsxfrm*( )

71675 XBD **<wchar.h>**

71676 **CHANGE HISTORY**

71677 First released in Issue 4. Derived from the MSE working draft.

71678 **Issue 5**

71679 Moved from ENHANCED I18N to BASE and the [ENOSYS] error is removed.

71680 The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

71681 **Issue 7**

71682 The *wcscoll_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API
71683 Set Part 4.

71684 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0719 [302], XSH/TC1-2008/0720 [283],
71685 and XSH/TC1-2008/0721 [283] are applied.

NAME

wcpcpy, wcscpy — copy a wide-character string, returning a pointer to its end

SYNOPSIS

```
#include <wchar.h>

CX  wchar_t *wcpcpy(wchar_t *restrict ws1, const wchar_t *restrict ws2);
    wchar_t *wcscpy(wchar_t *restrict ws1, const wchar_t *restrict ws2);
```

DESCRIPTION

CX For *wcscpy*(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *wcpcpy*() and *wcscpy*() functions shall copy the wide-character string pointed to by *ws2* (including the terminating null wide-character code) into the array pointed to by *ws1*.

The application shall ensure that there is room for at least *wcslen*(*ws2*)+1 wide characters in the *ws1* array, and that the *ws2* and *ws1* arrays do not overlap.

If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

CX The *wcpcpy*() function shall return a pointer to the terminating null wide-character code copied into the *ws1* buffer.

The *wcscpy*() function shall return *ws1*.

No return values are reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 6

The *wcscpy*() prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

Issue 7

The *wcpcpy*() function is added from The Open Group Technical Standard, 2006, Extended API Set Part 1.

NAME

wcscspn ‡'get the length of a complementary wide substring

SYNOPSIS

```
#include <wchar.h>

size_t wcscspn(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcscspn*( ) function shall compute the length (in wide characters) of the maximum initial segment of the wide-character string pointed to by *ws1* which consists entirely of wide-character codes *not* from the wide-character string pointed to by *ws2*.

RETURN VALUE

The *wcscspn*( ) function shall return the length of the initial substring of *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

wcsspn( )

XBD **<wchar.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The RETURN VALUE section is updated to indicate that *wcscspn*( ) returns the length of *ws1*, rather than *ws1* itself.

71759 **NAME**

71760 wcsdup ‡'duplicate a wide-character string

71761 **SYNOPSIS**

71762 CX
```
#include <wchar.h>

wchar_t *wcsdup(const wchar_t *string);
```

71763

71764 **DESCRIPTION**

71765 The *wcsdup*( ) function is the wide-character equivalent of the *strdup*( ) function.

71766 The *wcsdup*( ) function shall return a pointer to a new wide-character string, allocated as if by a
71767 call to *malloc*( ), which is the duplicate of the wide-character string *string*. The returned pointer
71768 can be passed to *free*( ). A null pointer is returned if the new wide-character string cannot be
71769 created.

71770 **RETURN VALUE**

71771 Upon successful completion, the *wcsdup*( ) function shall return a pointer to the newly allocated
71772 wide-character string. Otherwise, it shall return a null pointer and set *errno* to indicate the error.

71773 **ERRORS**

71774 The *wcsdup*( ) function shall fail if:

71775 [ENOMEM] Memory large enough for the duplicate string could not be allocated.

71776 **EXAMPLES**

71777 None.

71778 **APPLICATION USAGE**

71779 For functions that allocate memory as if by *malloc*( ), the application should release such memory
71780 when it is no longer required by a call to *free*( ). For *wcsdup*( ), this is the return value.

71781 **RATIONALE**

71782 None.

71783 **FUTURE DIRECTIONS**

71784 None.

71785 **SEE ALSO**

71786 *free*( ), *strdup*( ), *wcscpy*( )

NAME

wcsftime ‡'convert date and time to a wide-character string

SYNOPSIS

```
#include <wchar.h>

size_t wcsftime(wchar_t *restrict wcs, size_t maxsize,
    const wchar_t *restrict format, const struct tm *restrict timeptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcsftime*( ) function shall be equivalent to the *strftime*( ) function, except that:

The argument *wcs* points to the initial element of an array of wide characters into which the generated output is to be placed.

The argument *maxsize* indicates the maximum number of wide characters to be placed in the output array.

The argument *format* is a wide-character string and the conversion specifications are replaced by corresponding sequences of wide characters. It is unspecified whether an encoding error occurs if the format string contains **wchar_t** values that do not correspond to members of the character set of the current locale.

CX Field widths specify the number of wide characters instead of the number of bytes.

The return value indicates the number of wide characters placed in the output array.

If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

If the total number of resulting wide-character codes including the terminating null wide-character code is no more than *maxsize*, *wcsftime*( ) shall return the number of wide-character codes placed into the array pointed to by *wcs*, not including the terminating null wide-character code. Otherwise, zero is returned and the contents of the array are unspecified.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

71840 [740] are applied.

NAME

wcslen, wcsnlen ‡'get length of a fixed-sized wide-character string

SYNOPSIS

```
#include <wchar.h>

size_t wcslen(const wchar_t *ws);
CX size_t wcsnlen(const wchar_t *ws, size_t maxlen);
```

DESCRIPTION

CX For *wcslen*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcslen*( ) function shall compute the number of wide-character codes in the wide-character string to which *ws* points, not including the terminating null wide-character code.

CX The *wcsnlen*( ) function shall compute the smaller of the number of wide characters in the array to which *ws* points, not including any terminating null wide-character code, and the value of *maxlen*. The *wcsnlen*( ) function shall never examine more than the first *maxlen* characters of the wide-character array pointed to by *ws*.

RETURN VALUE

The *wcslen*( ) function shall return the length of *ws*.

CX The *wcsnlen*( ) function shall return the number of wide characters preceding the first null wide-character code in the array to which *ws* points, if *ws* contains a null wide-character code within the first *maxlen* wide characters; otherwise, it shall return *maxlen*.

No return values are reserved to indicate an error.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 7

The *wcsnlen*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 1.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0390 [560] is applied.

71882 **NAME**

71883 wcsncasecmp, wcsncasecmp_l ‡'case-insensitive wide-character string comparison

71884 **SYNOPSIS**

71885 CX
```
#include <wchar.h>

int wcsncasecmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);
int wcsncasecmp_l(const wchar_t *ws1, const wchar_t *ws2,
    size_t n, locale_t locale);
```

71889 **DESCRIPTION**

71890 Refer to *wcscasecmp( )*.

71891 **NAME**

71892 wcsncat ‡'concatenate a wide-character string with part of another

71893 **SYNOPSIS**

71894 ```
#include <wchar.h>
```

71895 ```
wchar_t *wcsncat(wchar_t *restrict ws1, const wchar_t *restrict ws2,
```

71896 ```
    size_t n);
```

71897 **DESCRIPTION**

71898 CX The functionality described on this reference page is aligned with the ISO C standard. Any
71899 conflict between the requirements described here and the ISO C standard is unintentional. This
71900 volume of POSIX.1-2017 defers to the ISO C standard.

71901 The *wcsncat*( ) function shall append not more than *n* wide-character codes (a null wide-
71902 character code and wide-character codes that follow it are not appended) from the array pointed
71903 to by *ws2* to the end of the wide-character string pointed to by *ws1*. The initial wide-character
71904 code of *ws2* shall overwrite the null wide-character code at the end of *ws1*. A terminating null
71905 wide-character code shall always be appended to the result. If copying takes place between
71906 objects that overlap, the behavior is undefined.

71907 **RETURN VALUE**

71908 The *wcsncat*( ) function shall return *ws1*; no return value is reserved to indicate an error.

71909 **ERRORS**

71910 No errors are defined.

71925 The *wcsncat*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

  
```

NAME

wcsncmp ‡'compare part of two wide-character strings

SYNOPSIS

```
#include <wchar.h>

int wcsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcsncmp*( ) function shall compare not more than *n* wide-character codes (wide-character codes that follow a null wide-character code are not compared) from the array pointed to by *ws1* to the array pointed to by *ws2*.

The sign of a non-zero return value shall be determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared.

RETURN VALUE

Upon successful completion, *wcsncmp*( ) shall return an integer greater than, equal to, or less than 0, if the possibly null-terminated array pointed to by *ws1* is greater than, equal to, or less than the possibly null-terminated array pointed to by *ws2*, respectively.

ERRORS

No errors are defined.

NAME

wcpncpy, wcsncpy — copy a fixed-size wide-character string, returning a pointer to its end

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcpncpy(wchar_t restrict *ws1, const wchar_t *restrict ws2,
    size_t n);
wchar_t *wcsncpy(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
```

DESCRIPTION

For *wcsncpy*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcpncpy*( ) and *wcsncpy*( ) functions shall copy not more than *n* wide-character codes (wide-character codes that follow a null wide-character code are not copied) from the array pointed to by *ws2* to the array pointed to by *ws1*. If copying takes place between objects that overlap, the behavior is undefined.

If the array pointed to by *ws2* is a wide-character string that is shorter than *n* wide-character codes, null wide-character codes shall be appended to the copy in the array pointed to by *ws1*, until *n* wide-character codes in all are written.

RETURN VALUE

If any null wide-character codes were written into the destination, the *wcpncpy*( ) function shall return the address of the first such null wide-character code. Otherwise, it shall return *&ws1*[*n*].

The *wcsncpy*( ) function shall return *ws1*.

No return values are reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

If there is no null wide-character code in the first *n* wide-character codes of the array pointed to by *ws2*, the result is not null-terminated.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

wcsrchr — wide-character string scanning operation

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcsrchr*( ) function shall locate the last occurrence of *wc* in the wide-character string pointed to by *ws*. The application shall ensure that the value of *wc* is a character representable as a type **wchar_t** and a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code shall be considered to be part of the wide-character string.

RETURN VALUE

Upon successful completion, *wcsrchr*( ) shall return a pointer to the wide-character code or a null pointer if *wc* does not occur in the wide-character string.

ERRORS

No errors are defined.

NAME

wcsnrtombs, wcsrtombs — convert a wide-character string to a character string (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t wcsnrtombs(char *restrict dst, const wchar_t **restrict src,
    size_t nwc, size_t len, mbstate_t *restrict ps);
size_t wcsrtombs(char *restrict dst, const wchar_t **restrict src,
    size_t len, mbstate_t *restrict ps);
```

DESCRIPTION

CX For *wcsrtombs*(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcsrtombs*() function shall convert a sequence of wide characters from the array indirectly pointed to by *src* into a sequence of corresponding characters, beginning in the conversion state described by the object pointed to by *ps*. If *dst* is not a null pointer, the converted characters shall then be stored into the array pointed to by *dst*. Conversion continues up to and including a terminating null wide character, which shall also be stored. Conversion shall stop earlier in the following cases:

When a code is reached that does not correspond to a valid character

When the next character would exceed the limit of *len* total bytes to be stored in the array pointed to by *dst* (and *dst* is not a null pointer)

Each conversion shall take place as if by a call to the *wcrtomb*() function.

If *dst* is not a null pointer, the pointer object pointed to by *src* shall be assigned either a null pointer (if conversion stopped due to reaching a terminating null wide character) or the address just past the last wide character converted (if any). If conversion stopped due to reaching a terminating null wide character, the resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *wcsrtombs*() function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence.

CX The *wcsnrtombs*() and *wcsrtombs*() functions need not be thread-safe if called with a NULL *ps* argument.

The *wcsnrtombs*() function shall be equivalent to the *wcsrtombs*() function, except that the conversion is limited to the first *nwc* wide characters.

The *wcsrtombs*() function shall not change the setting of *errno* if successful.

The behavior of these functions shall be affected by the *LC_CTYPE* category of the current locale.

The implementation shall behave as if no function defined in System Interfaces volume of POSIX.1-2017 calls these functions.

RETURN VALUE

If conversion stops because a code is reached that does not correspond to a valid character, an encoding error occurs. In this case, these functions shall store the value of the macro [EILSEQ] in *errno* and return (**size_t**)–1; the conversion state is undefined. Otherwise, these functions shall return the number of bytes in the resulting character sequence, not including the terminating null (if any).

72125 **ERRORS**

72126 These functions shall fail if:

72127 [EILSEQ] A wide-character code does not correspond to a valid character.

72128 These functions may fail if:

72129 CX [EINVAL] *ps* points to an object that contains an invalid conversion state.

72130 **EXAMPLES**

72131 None.

72132 **APPLICATION USAGE**

72133 None.

72134 **RATIONALE**

72135 None.

72136 **FUTURE DIRECTIONS**

72137 None.

72138 **SEE ALSO**

72141 **CHANGE HISTORY**

72142 First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995
72143 (E).

72144 **Issue 6**

72145 In the DESCRIPTION, a note on using this function in a threaded application is added.

72146 Extensions beyond the ISO C standard are marked.

72147 The normative text is updated to avoid use of the term ``must'' for application requirements.

72148 The *wcsrtombs*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

72149 **Issue 7**

72150 Austin Group Interpretation 1003.1-2001 #148 is applied, clarifying that the *wcsrtombs*( ) function
72151 need not be thread-safe if called with a NULL *ps* argument.

72152 Austin Group Interpretation 1003.1-2001 #170 is applied.

72153 The *wcsnrtombs*( ) function is added from The Open Group Technical Standard, 2006, Extended
72154 API Set Part 1.

72155 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0722 [109,105] is applied.

72156 **NAME**

72157 wcsspn ‡'get the length of a wide substring

72158 **SYNOPSIS**

72159 `#include <wchar.h>`

72160 `size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2);`

72161 **DESCRIPTION**

72162 CX The functionality described on this reference page is aligned with the ISO C standard. Any
72163 conflict between the requirements described here and the ISO C standard is unintentional. This
72164 volume of POSIX.1-2017 defers to the ISO C standard.

72165 The *wcsspn*( ) function shall compute the length (in wide characters) of the maximum initial
72166 segment of the wide-character string pointed to by *ws1* which consists entirely of wide-character
72167 codes from the wide-character string pointed to by *ws2*.

72168 **RETURN VALUE**

72169 The *wcsspn*( ) function shall return the length of the initial substring of *ws1*; no return value is
72170 reserved to indicate an error.

72171 **ERRORS**

72172 No errors are defined.

72173 **EXAMPLES**

72174 None.

72175 **APPLICATION USAGE**

72176 None.

72186 **Issue 5**

72187 The RETURN VALUE section is updated to indicate that *wcsspn*( ) returns the length of *ws1*
72188 rather that *ws1* itself.

NAME

wcsstr ‡'find a wide-character substring

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcsstr(const wchar_t *restrict ws1,
    const wchar_t *restrict ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wcsstr*( ) function shall locate the first occurrence in the wide-character string pointed to by *ws1* of the sequence of wide characters (excluding the terminating null wide character) in the wide-character string pointed to by *ws2*.

RETURN VALUE

Upon successful completion, *wcsstr*( ) shall return a pointer to the located wide-character string, or a null pointer if the wide-character string is not found.

If *ws2* points to a wide-character string with zero length, the function shall return *ws1*.

Issue 6

The *wcsstr*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

NAME

wcstod, wcstof, wcstold — convert a wide-character string to a double-precision number

SYNOPSIS

```
#include <wchar.h>

double wcstod(const wchar_t *restrict nptr, wchar_t **restrict endptr);
float wcstof(const wchar_t *restrict nptr, wchar_t **restrict endptr);
long double wcstold(const wchar_t *restrict nptr,
    wchar_t **restrict endptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

These functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **double**, **float**, and **long double** representation, respectively. First, they shall decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as a floating-point constant or representing infinity or NaN
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional `'+'` or `'−'` sign, then one of the following:

A non-empty sequence of decimal digits optionally containing a radix character; then an optional exponent part consisting of the wide character `'e'` or the wide character `'E'`, optionally followed by a `'+'` or `'−'` wide character, and then followed by one or more decimal digits

A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character; then an optional binary exponent part consisting of the wide character `'p'` or the wide character `'P'`, optionally followed by a `'+'` or `'−'` wide character, and then followed by one or more decimal digits

One of INF or INFINITY, or any other wide string equivalent except for case

One of NAN or NAN(*n-wchar-sequence*$_{opt}$), or any other wide string ignoring case in the NAN part, where:

```
n-wchar-sequence:
    digit
    nondigit
    n-wchar-sequence digit
    n-wchar-sequence nondigit
```

The subject sequence is defined as the longest initial subsequence of the input wide string, starting with the first non-white-space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide string is not of the expected form.

If the subject sequence has the expected form for a floating-point number, the sequence of wide characters starting with the first digit or the radix character (whichever occurs first) shall be interpreted as a floating constant according to the rules of the C language, except that the radix character shall be used in place of a period, and that if neither an exponent part nor a radix character appears in a decimal floating-point number, or if a binary exponent part does not appear in a hexadecimal floating-point number, an exponent part of the appropriate type with value zero shall be assumed to follow the last digit in the string. If the subject sequence begins with a <hyphen-minus>, the sequence shall be interpreted as negated. A wide-character sequence INF or INFINITY shall be interpreted as an infinity, if representable in the return type, else as if it were a floating constant that is too large for the range of the return type. A wide-character sequence NAN or NAN(n-*wchar-sequence*$_{opt}$) shall be interpreted as a quiet NaN, if supported in the return type, else as if it were a subject sequence part that does not have the expected form; the meaning of the n-wchar sequences is implementation-defined. A pointer to the final wide string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

If the subject sequence has the hexadecimal form and FLT_RADIX is a power of 2, the conversion shall be rounded in an implementation-defined manner.

CX The radix character shall be as defined in the current locale (category *LC_NUMERIC*). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a <period> (`'.'`).

CX In other than the C or POSIX locale, additional locale-specific subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

These functions shall not change the setting of *errno* if successful.

Since 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstod*( ), *wcstof*( ), or *wcstold*( ), then check *errno*.

RETURN VALUE

Upon successful completion, these functions shall return the converted value. If no conversion could be performed, 0 shall be returned CX and *errno* may be set to [EINVAL].

If the correct value is outside the range of representable values, ±HUGE_VAL, ±HUGE_VALF, or ±HUGE_VALL shall be returned (according to the sign of the value), and *errno* shall be set to [ERANGE].

If the correct value would cause underflow, a value whose magnitude is no greater than the smallest normalized positive number in the return type shall be returned and *errno* set to [ERANGE].

ERRORS

The *wcstod*( ) function shall fail if:

[ERANGE] The value to be returned would cause overflow or underflow.

The *wcstod*( ) function may fail if:

CX [EINVAL] No conversion could be performed.

EXAMPLES

None.

APPLICATION USAGE

If the subject sequence has the hexadecimal form and FLT_RADIX is not a power of 2, and the result is not exactly representable, the result should be one of the two numbers in the appropriate internal format that are adjacent to the hexadecimal floating source value, with the extra stipulation that the error should have a correct sign for the current rounding direction.

If the subject sequence has the decimal form and at most DECIMAL_DIG (defined in **<float.h>**) significant digits, the result should be correctly rounded. If the subject sequence *D* has the decimal form and more than DECIMAL_DIG significant digits, consider the two bounding, adjacent decimal strings *L* and *U*, both having DECIMAL_DIG significant digits, such that the values of *L*, *D*, and *U* satisfy "`L <= D <= U`". The result should be one of the (equal or adjacent) values that would be obtained by correctly rounding *L* and *U* according to the current rounding direction, with the extra stipulation that the error with respect to *D* should have a correct sign for the current rounding direction.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO/IEC 9899: 1999 standard:

- The *wcstod*( ) prototype is updated.
- The *wcstof*( ) and *wcstold*( ) functions are added.
- If the correct value for *wcstod*( ) would cause underflow, the return value changed from 0 (as specified in Issue 5) to the smallest normalized positive number.
- The DESCRIPTION, RETURN VALUE, and APPLICATION USAGE sections are extensively updated.

ISO/IEC 9899: 1999 standard, Technical Corrigendum 1 is incorporated.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/66 is applied, correcting the second paragraph in the RETURN VALUE section.

72353 **Issue 7**

72354 Austin Group Interpretation 1003.1-2001 #015 is applied.

72355 POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0723 [302] and XSH/TC1-2008/0724
72356 [105] are applied.

72357 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0391 [584] and XSH/TC2-2008/0392
72358 [796] are applied.

```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

These functions shall be equivalent to the *wcstol*( ), *wcstoll*( ), *wcstoul*( ), and *wcstoull*( ) functions, respectively, except that the initial portion of the wide string shall be converted to **intmax_t** and **uintmax_t** representation, respectively.

RETURN VALUE

These functions shall return the converted value, if any.

If no conversion could be performed, zero shall be returned. If the correct value is outside the range of representable values, {INTMAX_MAX}, {INTMAX_MIN}, or {UINTMAX_MAX} shall be returned (according to the return type and sign of the value, if any), and *errno* shall be set to [ERANGE].

ERRORS

These functions shall fail if:

[EINVAL] The value of *base* is not supported.

[ERANGE] The value to be returned is not representable.

These functions may fail if:

[EINVAL] No conversion could be performed.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899: 1999 standard.

NAME

wcstok ‡'split a wide-character string into tokens

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcstok(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    wchar_t **restrict ptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

A sequence of calls to *wcstok*( ) shall break the wide-character string pointed to by *ws1* into a sequence of tokens, each of which shall be delimited by a wide-character code from the wide-character string pointed to by *ws2*. The *ptr* argument points to a caller-provided **wchar_t** pointer into which the *wcstok*( ) function shall store information necessary for it to continue scanning the same wide-character string.

The first call in the sequence has *ws1* as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by *ws2* may be different from call to call.

The first call in the sequence shall search the wide-character string pointed to by *ws1* for the first wide-character code that is *not* contained in the current separator string pointed to by *ws2*. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by *ws1* and *wcstok*( ) shall return a null pointer. If such a wide-character code is found, it shall be the start of the first token.

The *wcstok*( ) function shall then search from there for a wide-character code that *is* contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by *ws1*, and subsequent searches for a token shall return a null pointer. If such a wide-character code is found, it shall be overwritten by a null wide character, which terminates the current token. The *wcstok*( ) function shall save a pointer to the following wide-character code, from which the next search for a token shall start.

Each subsequent call, with a null pointer as the value of the first argument, shall start searching from the saved pointer and behave as described above.

The implementation shall behave as if no function calls *wcstok*( ).

RETURN VALUE

Upon successful completion, the *wcstok*( ) function shall return a pointer to the first wide-character code of a token. Otherwise, if there is no token, *wcstok*( ) shall return a null pointer.

ERRORS

No errors are defined.

72437 **EXAMPLES**

72438 None.

72439 **APPLICATION USAGE**

72440 None.

72441 **RATIONALE**

72442 None.

72448 First released in Issue 4.

72449 **Issue 5**

72450 Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, a third argument is
72451 added to the definition of *wcstok*( ) in the SYNOPSIS.

72452 **Issue 6**

72453 The *wcstok*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcstol, wcstoll ‡'convert a wide-character string to a long integer

SYNOPSIS

```
#include <wchar.h>

long wcstol(const wchar_t *restrict nptr, wchar_t **restrict endptr,
    int base);
long long wcstoll(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

These functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **long** and **long long**, respectively. First, they shall decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to an integer, and return the result.

If *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a '+' or '−' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0' optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F') with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a '+' or '−' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* shall be permitted. If the value of *base* is 16, the wide-character code representations of 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white-space wide-character code that is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and *base* is 0, the sequence of wide-character codes starting with the first digit shall be interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a <hyphen-minus>, the value resulting from the conversion shall be negated. A pointer to the final wide-character string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

72500 CX In other than the C or POSIX locale, additional locale-specific subject sequence forms may be
72501 accepted.

72502 If the subject sequence is empty or does not have the expected form, no conversion shall be
72503 performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that
72504 *endptr* is not a null pointer.

72505 These functions shall not change the setting of *errno* if successful.

72506 Since 0, {LONG_MIN} or {LLONG_MIN} and {LONG_MAX} or {LLONG_MAX} are returned on
72507 error and are also valid returns on success, an application wishing to check for error situations
72508 should set *errno* to 0, then call *wcstol*( ) or *wcstoll*( ), then check *errno*.

72509 **RETURN VALUE**

72510 Upon successful completion, these functions shall return the converted value, if any. If no
72511 CX conversion could be performed, 0 shall be returned and *errno* may be set to indicate the error. If
72512 the correct value is outside the range of representable values, {LONG_MIN}, {LONG_MAX},
72513 {LLONG_MIN}, or {LLONG_MAX} shall be returned (according to the sign of the value), and
72514 *errno* set to [ERANGE].

72515 **ERRORS**

72516 These functions shall fail if:

72517 CX [EINVAL] The value of *base* is not supported.

72518 [ERANGE] The value to be returned is not representable.

72519 These functions may fail if:

72520 CX [EINVAL] No conversion could be performed.

72521 **EXAMPLES**

72522 None.

72523 **APPLICATION USAGE**

72524 None.

72525 **RATIONALE**

72526 None.

72527 **FUTURE DIRECTIONS**

72532 **CHANGE HISTORY**

72533 First released in Issue 4. Derived from the MSE working draft.

72534 **Issue 5**

72535 The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

72536 **Issue 6**

72537 Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO/IEC 9899: 1999 standard:

The *wcstol*( ) prototype is updated.

The *wcstoll*( ) function is added.

Issue 7

SD5-XSH-ERN-56 is applied, removing the reference to **unsigned long** and **unsigned long long** from the DESCRIPTION.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0725 [105] is applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0393 [584] and XSH/TC2-2008/0394 [796] are applied.

72551 **NAME**

72552 wcstold — convert a wide-character string to a double-precision number

72553 **SYNOPSIS**

72554 ```
#include <wchar.h>
```

72555 ```
long double wcstold(const wchar_t *restrict nptr,
```

72556 ```
    wchar_t **restrict endptr);
```

72557 **DESCRIPTION**

72558 Refer to *wcstod( )*.

  
```

72559 **NAME**

72560 wcstoll ‡'convert a wide-character string to a long integer

72561 **SYNOPSIS**

72562
```
#include <wchar.h>
```

72563
```
long long wcstoll(const wchar_t *restrict nptr,
```
72564
```
    wchar_t **restrict endptr, int base);
```

72565 **DESCRIPTION**

72566 Refer to *wcstol( )*.

72567 **NAME**

72568 wcstombs ‡'convert a wide-character string to a character string

72569 **SYNOPSIS**

72570 ```
#include <stdlib.h>
```

72571 ```
size_t wcstombs(char *restrict s, const wchar_t *restrict pwcs,
```

72572 ```
    size_t n);
```

72573 **DESCRIPTION**

72574 CX The functionality described on this reference page is aligned with the ISO C standard. Any
72575 conflict between the requirements described here and the ISO C standard is unintentional. This
72576 volume of POSIX.1-2017 defers to the ISO C standard.

72577 The *wcstombs*( ) function shall convert the sequence of wide-character codes that are in the array
72578 pointed to by *pwcs* into a sequence of characters that begins in the initial shift state and store
72579 these characters into the array pointed to by *s*, stopping if a character would exceed the limit of *n*
72580 total bytes or if a null byte is stored. Each wide-character code shall be converted as if by a call to
72581 *wctomb*( ), except that the shift state of *wctomb*( ) shall not be affected.

72582 The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

72583 No more than *n* bytes shall be modified in the array pointed to by *s*. If copying takes place
72584 CX between objects that overlap, the behavior is undefined. If *s* is a null pointer, *wcstombs*( ) shall
72585 return the length required to convert the entire array regardless of the value of *n*, but no values
72586 are stored.

72587 **RETURN VALUE**

72588 If a wide-character code is encountered that does not correspond to a valid character (of one or
72589 more bytes each), *wcstombs*( ) shall return (**size_t**)–1. Otherwise, *wcstombs*( ) shall return the
72590 number of bytes stored in the character array, not including any terminating null byte. The array
72591 shall not be null-terminated if the value returned is *n*.

72592 **ERRORS**

72593 The *wcstombs*( ) function shall fail if:

72594 CX [EILSEQ] A wide-character code does not correspond to a valid character.

72595 **EXAMPLES**

72596 None.

72597 **APPLICATION USAGE**

72598 None.

72599 **RATIONALE**

72600 None.

72601 **FUTURE DIRECTIONS**

72602 None.

72606 **CHANGE HISTORY**

72607 First released in Issue 4. Derived from the ISO C standard.

  
```

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

The DESCRIPTION states the effect of when *s* is a null pointer.

The [EILSEQ] error condition is added.

The *wcstombs*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

Issue 7

Austin Group Interpretations 1003.1-2001 #156 and #170 are applied.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0726 [109] is applied.

72617 **NAME**

72618 wcstoul, wcstoull ‡'convert a wide-character string to an unsigned long

72619 **SYNOPSIS**

72620
```
#include <wchar.h>
```

72621
```
unsigned long wcstoul(const wchar_t *restrict nptr,
```
72622
```
    wchar_t **restrict endptr, int base);
```
72623
```
unsigned long long wcstoull(const wchar_t *restrict nptr,
```
72624
```
    wchar_t **restrict endptr, int base);
```

72625 **DESCRIPTION**

72626 CX The functionality described on this reference page is aligned with the ISO C standard. Any
72627 conflict between the requirements described here and the ISO C standard is unintentional. This
72628 volume of POSIX.1-2017 defers to the ISO C standard.

72629 The *wcstoul*( ) and *wcstoull*( ) functions shall convert the initial portion of the wide-character
72630 string pointed to by *nptr* to **unsigned long** and **unsigned long long** representation, respectively.
72631 First, they shall decompose the input wide-character string into three parts:

72632 1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by
72633 *iswspace*( ))

72634 2. A subject sequence interpreted as an integer represented in some radix determined by the
72635 value of *base*

72636 3. A final wide-character string of one or more unrecognized wide-character codes,
72637 including the terminating null wide-character code of the input wide-character string

72638 Then they shall attempt to convert the subject sequence to an unsigned integer, and return the
72639 result.

72640 If *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant,
72641 or hexadecimal constant, any of which may be preceded by a '+' or '−' sign. A decimal
72642 constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal
72643 constant consists of the prefix '0' optionally followed by a sequence of the digits '0' to '7'
72644 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the
72645 decimal digits and letters 'a' (or 'A') to 'f' (or 'F') with values 10 to 15 respectively.

72646 If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence
72647 of letters and digits representing an integer with the radix specified by *base*, optionally preceded
72648 by a '+' or '−' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z'
72649 (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less
72650 than that of *base* shall be permitted. If the value of *base* is 16, the wide-character codes 0x or 0X
72651 may optionally precede the sequence of letters and digits, following the sign if present.

72652 The subject sequence is defined as the longest initial subsequence of the input wide-character
72653 string, starting with the first wide-character code that is not white space and is of the expected
72654 form. The subject sequence contains no wide-character codes if the input wide-character string is
72655 empty or consists entirely of white-space wide-character codes, or if the first wide-character
72656 code that is not white space is other than a sign or a permissible letter or digit.

72657 If the subject sequence has the expected form and *base* is 0, the sequence of wide-character codes
72658 starting with the first digit shall be interpreted as an integer constant. If the subject sequence has
72659 the expected form and the value of *base* is between 2 and 36, it shall be used as the base for
72660 conversion, ascribing to each letter its value as given above. If the subject sequence begins with a
72661 <hyphen-minus>, the value resulting from the conversion shall be negated. A pointer to the final
72662 wide-character string shall be stored in the object pointed to by *endptr*, provided that *endptr* is

not a null pointer.

CX In other than the C or POSIX locale, additional locale-specific subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

These functions shall not change the setting of *errno* if successful.

Since 0, {ULONG_MAX}, and {ULLONG_MAX} are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstoul*( ) or *wcstoull*( ), then check *errno*.

RETURN VALUE

Upon successful completion, the *wcstoul*( ) and *wcstoull*( ) functions shall return the converted CX value, if any. If no conversion could be performed, 0 shall be returned and *errno* may be set to indicate the error. If the correct value is outside the range of representable values, {ULONG_MAX} or {ULLONG_MAX} respectively shall be returned and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [EINVAL] The value of *base* is not supported.

[ERANGE] The value to be returned is not representable.

These functions may fail if:

CX [EINVAL] No conversion could be performed.

EXAMPLES

None.

APPLICATION USAGE

NAME

wcstoumax ‡'convert a wide-character string to an integer type

SYNOPSIS

```
#include <stddef.h>
#include <inttypes.h>

uintmax_t wcstoumax(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

Refer to *wcstoimax( )*.

NAME

wcswidth ‡'number of column positions of a wide-character string

SYNOPSIS

XSI
```
#include <wchar.h>

int wcswidth(const wchar_t *pwcs, size_t n);
```

DESCRIPTION

The *wcswidth*( ) function shall determine the number of column positions required for *n* wide-character codes (or fewer than *n* wide-character codes if a null wide-character code is encountered before *n* wide-character codes are exhausted) in the string pointed to by *pwcs*.

RETURN VALUE

The *wcswidth*( ) function either shall return 0 (if *pwcs* points to a null wide-character code), or return the number of column positions to be occupied by the wide-character string pointed to by *pwcs*, or return –1 (if any of the first *n* wide-character codes in the wide-character string pointed to by *pwcs* is not a printable wide-character code).

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

This function was removed from the final ISO/IEC 9899:1990/Amendment 1:1995 (E), and the return value for a non-printable wide character is not specified.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 6

The Open Group Corrigendum U021/11 is applied. The function is marked as an extension.

NAME

wcsxfrm, wcsxfrm_l ‡'wide-character string transformation

SYNOPSIS

```
#include <wchar.h>

size_t wcsxfrm(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
CX  size_t wcsxfrm_l(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n, locale_t locale);
```

DESCRIPTION

CX For *wcsxfrm*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

CX The *wcsxfrm*( ) and *wcsxfrm_l*( ) functions shall transform the wide-character string pointed to by *ws2* and place the resulting wide-character string into the array pointed to by *ws1*. The transformation shall be such that if *wcscmp*( ) is applied to two transformed wide strings, it shall return a value greater than, equal to, or less than 0, corresponding to the result of *wcscoll*( ) and *wcscoll_l*( ) applied to the same two original wide-character strings, and the same *LC_COLLATE* CX category of the current locale or the locale object *locale*, respectively. No more than *n* wide-character codes shall be placed into the resulting array pointed to by *ws1*, including the terminating null wide-character code. If *n* is 0, *ws1* is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.

CX The *wcsxfrm*( ) and *wcsxfrm_l*( ) functions shall not change the setting of *errno* if successful.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set *errno* to 0, then call *wcsxfrm*( ) or *wcsxfrm_l*( ), then check *errno*.

The behavior is undefined if the *locale* argument to *wcsxfrm_l*( ) is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

CX The *wcsxfrm*( ) and *wcsxfrm_l*( ) functions shall return the length of the transformed wide-character string (not including the terminating null wide-character code). If the value returned is *n* or more, the contents of the array pointed to by *ws1* are unspecified.

CX On error, the *wcsxfrm*( ) and *wcsxfrm_l*( ) functions may set *errno*, but no return value is reserved to indicate an error.

ERRORS

These functions may fail if:

CX [EINVAL] The wide-character string pointed to by *ws2* contains wide-character codes outside the domain of the collating sequence.

EXAMPLES

None.

APPLICATION USAGE

The transformation function is such that two transformed wide-character strings can be ordered by *wcscmp*( ) as appropriate to collating sequence information in the current locale (category *LC_COLLATE*).

The fact that when *n* is 0 *ws1* is permitted to be a null pointer is useful to determine the size of the *ws1* array prior to making the transformation.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

Moved from ENHANCED I18N to BASE and the [ENOSYS] error is removed.

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

In earlier versions, this function was required to return –1 on error.

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

> In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The *wcsxfrm*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

Issue 7

The *wcsxfrm_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0728 [302], XSH/TC1-2008/0729 [283], XSH/TC1-2008/0730 [283], and XSH/TC1-2008/0731 [302] are applied.

NAME

wctob ‡'wide-character to single-byte conversion

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int wctob(wint_t c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wctob*( ) function shall determine whether *c* corresponds to a member of the extended character set whose character representation is a single byte when in the initial shift state.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

The *wctob*( ) function shall return EOF if *c* does not correspond to a character with length one in the initial shift state. Otherwise, it shall return the single-byte representation of that character as an **unsigned char** converted to **int**.

ERRORS

No errors are defined.

EXAMPLES

CHANGE HISTORY

First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E).

72856 **NAME**

72857 wctomb ‡'convert a wide-character code to a character

72858 **SYNOPSIS**

72859 `#include <stdlib.h>`

72860 `int wctomb(char *s, wchar_t wchar);`

72861 **DESCRIPTION**

72862 CX The functionality described on this reference page is aligned with the ISO C standard. Any
72863 conflict between the requirements described here and the ISO C standard is unintentional. This
72864 volume of POSIX.1-2017 defers to the ISO C standard.

72865 The *wctomb*( ) function shall determine the number of bytes needed to represent the character
72866 corresponding to the wide-character code whose value is *wchar* (including any change in the
72867 shift state). It shall store the character representation (possibly multiple bytes and any special
72868 bytes to change shift state) in the array object pointed to by *s* (if *s* is not a null pointer). At most
72869 {MB_CUR_MAX} bytes shall be stored. If *wchar* is 0, a null byte shall be stored, preceded by any
72870 shift sequence needed to restore the initial shift state, and *wctomb*( ) shall be left in the initial shift
72871 state.

72872 CX The behavior of this function is affected by the *LC_CTYPE* category of the current locale. For a
72873 state-dependent encoding, this function shall be placed into its initial state by a call for which its
72874 character pointer argument, *s*, is a null pointer. Subsequent calls with *s* as other than a null
72875 pointer shall cause the internal state of the function to be altered as necessary. A call with *s* as a
72876 null pointer shall cause this function to return a non-zero value if encodings have state
72877 dependency, and 0 otherwise. Changing the *LC_CTYPE* category causes the shift state of this
72878 function to be unspecified.

72879 The *wctomb*( ) function need not be thread-safe.

72880 The implementation shall behave as if no function defined in this volume of POSIX.1-2017 calls
72881 *wctomb*( ).

72882 **RETURN VALUE**

72883 If *s* is a null pointer, *wctomb*( ) shall return a non-zero or 0 value, if character encodings,
72884 respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, *wctomb*( )
72885 shall return –1 if the value of *wchar* does not correspond to a valid character, or return the
72886 number of bytes that constitute the character corresponding to the value of *wchar*.

72887 In no case shall the value returned be greater than the value of the {MB_CUR_MAX} macro.

72888 **ERRORS**

72889 The *wctomb*( ) function shall fail if:

72890 CX [EILSEQ] An invalid wide-character code is detected.

72891 **EXAMPLES**

72892 None.

72893 **APPLICATION USAGE**

72894 None.

72895 **RATIONALE**

72896 None.

72897 **FUTURE DIRECTIONS**

72898 None.

NAME

wctrans, wctrans_l ‡'define character mapping

SYNOPSIS

```
#include <wctype.h>

wctrans_t wctrans(const char *charclass);
wctrans_t wctrans_l(const char *charclass, locale_t locale);
```

DESCRIPTION

For *wctrans*(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wctrans*() and *wctrans_l*() functions are defined for valid character mapping names identified in the current locale. The *charclass* is a string identifying a generic character mapping name for which codeset-specific information is required. The following character mapping names are defined in all locales: **tolower** and **toupper**.

These functions shall return a value of type **wctrans_t**, which can be used as the second argument to subsequent calls of *towctrans*() and *towctrans_l*().

The *wctrans*() and *wctrans_l*() functions shall determine values of **wctrans_t** according to the rules of the coded character set defined by character mapping information in the current locale or in the locale represented by *locale*, respectively (category *LC_CTYPE*).

The values returned by *wctrans*() shall be valid until a call to *setlocale*() that modifies the category *LC_CTYPE*.

The values returned by *wctrans_l*() shall be valid only in calls to *towctrans_l*() with a locale represented by *locale* with the same *LC_CTYPE* category value.

The behavior is undefined if the *locale* argument to *wctrans_l*() is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

The *wctrans*() and *wctrans_l*() functions shall return 0 and may set *errno* to indicate the error if the given character mapping name is not valid for the current locale (category *LC_CTYPE*); otherwise, they shall return a non-zero object of type **wctrans_t** that can be used in calls to *towctrans*() and *towctrans_l*().

ERRORS

These functions may fail if:

[EINVAL] The character mapping name pointed to by *charclass* is not valid in the current locale.

CHANGE HISTORY

First released in Issue 5. Derived from ISO/IEC 9899: 1990/Amendment 1: 1995 (E).

Issue 7

The *wctrans_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0732 [302], XSH/TC1-2008/0733 [289], XSH/TC1-2008/0734 [283], and XSH/TC1-2008/0735 [283] are applied.

NAME

wctype, wctype_l ‡'define character class

SYNOPSIS

```
#include <wctype.h>

wctype_t wctype(const char *property);
wctype_t wctype_l(const char *property, locale_t locale);
```

DESCRIPTION

For *wctype*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wctype*( ) and *wctype_l*( ) functions are defined for valid character class names as defined in the current locale or in the locale represented by *locale*, respectively.

The *property* argument is a string identifying a generic character class for which codeset-specific type information is required. The following character class names shall be defined in all locales:

alnum	**digit**	**punct**
alpha	**graph**	**space**
blank	**lower**	**upper**
cntrl	**print**	**xdigit**

Additional character class names defined in the locale definition file (category *LC_CTYPE*) can also be specified.

These functions shall return a value of type **wctype_t**, which can be used as the second argument to subsequent calls of *iswctype*( ) and *iswctype_l*( ).

The *wctype*( ) and *wctype_l*( ) functions shall determine values of **wctype_t** according to the rules of the coded character set defined by character type information in the current locale or in the locale represented by *locale*, respectively (category *LC_CTYPE*).

The values returned by *wctype*( ) shall be valid until a call to *setlocale*( ) that modifies the category *LC_CTYPE*.

The values returned by *wctype_l*( ) shall be valid only in calls to *iswctype_l*( ) with a locale represented by *locale* with the same *LC_CTYPE* category value.

The behavior is undefined if the *locale* argument to *wctype_l*( ) is the special locale object LC_GLOBAL_LOCALE or is not a valid locale object handle.

RETURN VALUE

The *wctype*( ) and *wctype_l*( ) functions shall return 0 if the given character class name is not valid for the current locale (category *LC_CTYPE*); otherwise, they shall return an object of type **wctype_t** that can be used in calls to *iswctype*( ) and *iswctype_l*( ).

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The following change has been made in this version for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

> The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 7

The *wctype_l( )* function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0736 [302], XSH/TC1-2008/0737 [283], and XSH/TC1-2008/0738 [283] are applied.

73021 **NAME**

73022 wcwidth ‡'number of column positions of a wide-character code

73023 **SYNOPSIS**

73024 XSI
```
#include <wchar.h>

int wcwidth(wchar_t wc);
```
73025

73026 **DESCRIPTION**

73027 The *wcwidth*( ) function shall determine the number of column positions required for the wide
73028 character *wc*. The application shall ensure that the value of *wc* is a character representable as a
73029 **wchar_t**, and is a wide-character code corresponding to a valid character in the current locale.

73030 **RETURN VALUE**

73031 The *wcwidth*( ) function shall either return 0 (if *wc* is a null wide-character code), or return the
73032 number of column positions to be occupied by the wide-character code *wc*, or return –1 (if *wc*
73033 does not correspond to a printable wide-character code).

73034 **ERRORS**

73035 No errors are defined.

73036 **EXAMPLES**

73037 None.

73038 **APPLICATION USAGE**

73039 This function was removed from the final ISO/IEC 9899:1990/Amendment 1:1995 (E), and the
73040 return value for a non-printable wide character is not specified.

73041 **RATIONALE**

73042 None.

73043 **FUTURE DIRECTIONS**

73044 None.

73045 **SEE ALSO**

73046 *wcswidth*( )

73047 XBD **<wchar.h>**

73048 **CHANGE HISTORY**

73049 First released as a World-wide Portability Interface in Issue 4. Derived from the MSE working
73050 draft.

73051 **Issue 6**

73052 The Open Group Corrigendum U021/12 is applied. This function is marked as an extension.

73053 The normative text is updated to avoid use of the term ``must'' for application requirements.

NAME

wmemchr ‡'find a wide character in memory

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *ws, wchar_t wc, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wmemchr*( ) function shall locate the first occurrence of *wc* in the initial *n* wide characters of the object pointed to by *ws*. This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially.

If *n* is zero, the application shall ensure that *ws* is a valid pointer and the function behaves as if no valid occurrence of *wc* is found.

RETURN VALUE

The *wmemchr*( ) function shall return a pointer to the located wide character, or a null pointer if the wide character does not occur in the object.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

Issue 6

The normative text is updated to avoid use of the term ``must'' for application requirements.

73090 **NAME**

73091 wmemcmp ‡'compare wide characters in memory

73092 **SYNOPSIS**

73093 `#include <wchar.h>`

73094 `int wmemcmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);`

73095 **DESCRIPTION**

73096 CX The functionality described on this reference page is aligned with the ISO C standard. Any
73097 conflict between the requirements described here and the ISO C standard is unintentional. This
73098 volume of POSIX.1-2017 defers to the ISO C standard.

73099 The *wmemcmp*( ) function shall compare the first *n* wide characters of the object pointed to by
73100 *ws1* to the first *n* wide characters of the object pointed to by *ws2*. This function shall not be
73101 affected by locale and all **wchar_t** values shall be treated identically. The null wide character and
73102 **wchar_t** values not corresponding to valid characters shall not be treated specially.

73103 If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function
73104 shall behave as if the two objects compare equal.

73105 **RETURN VALUE**

73106 The *wmemcmp*( ) function shall return an integer greater than, equal to, or less than zero,
73107 respectively, as the object pointed to by *ws1* is greater than, equal to, or less than the object
73108 pointed to by *ws2*.

73109 **ERRORS**

73110 No errors are defined.

73126 The normative text is updated to avoid use of the term ``must'' for application requirements.

73127 **NAME**

73128 wmemcpy ‡'copy wide characters in memory

73129 **SYNOPSIS**

73130
```
#include <wchar.h>
```

73131
```
wchar_t *wmemcpy(wchar_t *restrict ws1, const wchar_t *restrict ws2,
```
73132
```
    size_t n);
```

73133 **DESCRIPTION**

73134 CX The functionality described on this reference page is aligned with the ISO C standard. Any
73135 conflict between the requirements described here and the ISO C standard is unintentional. This
73136 volume of POSIX.1-2017 defers to the ISO C standard.

73137 The *wmemcpy*( ) function shall copy *n* wide characters from the object pointed to by *ws2* to the
73138 object pointed to by *ws1*. This function shall not be affected by locale and all **wchar_t** values
73139 shall be treated identically. The null wide character and **wchar_t** values not corresponding to
73140 valid characters shall not be treated specially.

73141 If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function
73142 shall copy zero wide characters.

73143 **RETURN VALUE**

73144 The *wmemcpy*( ) function shall return the value of *ws1*.

73145 **ERRORS**

73146 No errors are defined.

73161 **Issue 6**

73162 The normative text is updated to avoid use of the term ``must'' for application requirements.

73163 The *wmemcpy*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wmemmove — copy wide characters in memory with overlapping areas

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemmove(wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-2017 defers to the ISO C standard.

The *wmemmove*( ) function shall copy *n* wide characters from the object pointed to by *ws2* to the object pointed to by *ws1*. Copying shall take place as if the *n* wide characters from the object pointed to by *ws2* are first copied into a temporary array of *n* wide characters that does not overlap the objects pointed to by *ws1* or *ws2*, and then the *n* wide characters from the temporary array are copied into the object pointed to by *ws1*.

This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially.

If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function shall copy zero wide characters.

RETURN VALUE

The *wmemmove*( ) function shall return the value of *ws1*.

NAME

wordexp, wordfree — perform word expansions

SYNOPSIS

```
#include <wordexp.h>

int wordexp(const char *restrict words, wordexp_t *restrict pwordexp,
    int flags);
void wordfree(wordexp_t *pwordexp);
```

DESCRIPTION

The *wordexp*( ) function shall perform word expansions as described in XCU Section 2.6 (on page 2353), subject to quoting as described in XCU Section 2.2 (on page 2346), and place the list of expanded words into the structure pointed to by *pwordexp*.

The *words* argument is a pointer to a string containing one or more words to be expanded. The expansions shall be the same as would be performed by the command line interpreter if *words* were the part of a command line representing the arguments to a utility. Therefore, the application shall ensure that *words* does not contain an unquoted <newline> character or any of the unquoted shell special characters `'|'`, `'&'`, `';'`, `'<'`, `'>'` except in the context of command substitution as specified in XCU Section 2.6.3 (on page 2357). It also shall not contain unquoted parentheses or braces, except in the context of command or variable substitution. The application shall ensure that every member of *words* which it expects to have expanded by *wordexp*( ) does not contain an unquoted initial comment character. The application shall also ensure that any words which it intends to be ignored (because they begin or continue a comment) are deleted from *words*. If the argument *words* contains an unquoted comment character (<number-sign>) that is the beginning of a token, *wordexp*( ) shall either treat the comment character as a regular character, or interpret it as a comment indicator and ignore the remainder of *words*.

The structure type **wordexp_t** is defined in the **<wordexp.h>** header and includes at least the following members:

Member Type	Member Name	Description
size_t	*we_wordc*	Count of words matched by *words*.
**char ** **	*we_wordv*	Pointer to list of expanded words.
size_t	*we_offs*	Slots to reserve at the beginning of *pwordexp* ~~*we*~~_*wordv*.

The *wordexp*( ) function shall store the number of generated words into *pwordexp* ~~*we*~~_*wordc* and a pointer to a list of pointers to words in *pwordexp* ~~*we*~~_*wordv*. Each individual field created during field splitting (see XCU Section 2.6.5, on page 2359) or pathname expansion (see XCU Section 2.6.6, on page 2360) shall be a separate word in the *pwordexp* ~~*we*~~_*wordv* list. The words shall be in order as described in XCU Section 2.6 (on page 2353). The first pointer after the last word pointer shall be a null pointer. The expansion of special parameters described in XCU Section 2.5.2 (on page 2350) is unspecified.

It is the caller's responsibility to allocate the storage pointed to by *pwordexp*. The *wordexp*( ) function shall allocate other space as needed, including memory pointed to by *pwordexp* ~~*we*~~_*wordv*. The *wordfree*( ) function frees any memory associated with *pwordexp* from a previous call to *wordexp*( ).

The *flags* argument is used to control the behavior of *wordexp*( ). The value of *flags* is the bitwise-inclusive OR of zero or more of the following constants, which are defined in **<wordexp.h>**:

73283 WRDE_APPEND Append words generated to the ones from a previous call to *wordexp*( ).

73284 WRDE_DOOFFS Make use of *pwordexp* ~~->~~*we_offs*. If this flag is set, *pwordexp* ~~->~~*we_offs* is
73285 used to specify how many null pointers to add to the beginning of
73286 *pwordexp* ~~->~~*we_wordv*. In other words, *pwordexp* ~~->~~*we_wordv* shall point to
73287 *pwordexp* ~~->~~*we_offs* null pointers, followed by *pwordexp* ~~->~~*we_wordc* word
73288 pointers, followed by a null pointer.

73289 WRDE_NOCMD If the implementation supports the utilities defined in the Shell and
73290 Utilities volume of POSIX.1-2017, fail if command substitution, as
73291 specified in XCU Section 2.6.3 (on page 2357), is requested.

73292 WRDE_REUSE The *pwordexp* argument was passed to a previous successful call to
73293 *wordexp*( ), and has not been passed to *wordfree*( ). The result shall be the
73294 same as if the application had called *wordfree*( ) and then called *wordexp*( )
73295 without WRDE_REUSE.

73296 WRDE_SHOWERR Do not redirect *stderr* to **/dev/null**.

73297 WRDE_UNDEF Report error on an attempt to expand an undefined shell variable.

73298 The WRDE_APPEND flag can be used to append a new set of words to those generated by a
73299 previous call to *wordexp*( ). The following rules apply to applications when two or more calls to
73300 *wordexp*( ) are made with the same value of *pwordexp* and without intervening calls to *wordfree*( ):

73301 1. The first such call shall not set WRDE_APPEND. All subsequent calls shall set it.

73302 2. All of the calls shall set WRDE_DOOFFS, or all shall not set it.

73303 3. After the second and each subsequent call, *pwordexp* ~~->~~*we_wordv* shall point to a list
73304 containing the following:

73305 a. Zero or more null pointers, as specified by WRDE_DOOFFS and
73306 *pwordexp* ~~->~~*we_offs*

73307 b. Pointers to the words that were in the *pwordexp* ~~->~~*we_wordv* list before the call, in
73308 the same order as before

73309 c. Pointers to the new words generated by the latest call, in the specified order

73310 4. The count returned in *pwordexp* ~~->~~*we_wordc* shall be the total number of words from all of
73311 the calls.

73312 5. The application can change any of the fields after a call to *wordexp*( ), but if it does it shall
73313 reset them to the original value before a subsequent call, using the same *pwordexp* value,
73314 to *wordfree*( ) or *wordexp*( ) with the WRDE_APPEND or WRDE_REUSE flag.

73315 If the implementation supports the utilities defined in the Shell and Utilities volume of
73316 POSIX.1-2017, and *words* contains an unquoted character ‡<newline>,'`|`', '`&`', '`;`', '`<`', '`>`',
73317 '`(`', '`)`', '`{`', '`}`'—in an inappropriate context, *wordexp*( ) shall fail, and the number of
73318 expanded words shall be 0.

73319 Unless WRDE_SHOWERR is set in *flags*, *wordexp*( ) shall redirect *stderr* to **/dev/null** for any
73320 utilities executed as a result of command substitution while expanding *words*. If
73321 WRDE_SHOWERR is set, *wordexp*( ) may write messages to *stderr* if syntax errors are detected
73322 while expanding *words*, unless the *stderr* stream has wide orientation in which case the behavior
73323 is undefined. It is unspecified whether any write errors encountered while outputting such
73324 messages will affect the *stderr* error indicator or the value of *errno*.

73325 The application shall ensure that if WRDE_DOOFFS is set, then *pwordexp* ~~->~~*we_offs* has the same

value for each *wordexp*( ) call and *wordfree*( ) call using a given *pwordexp*.

The results are unspecified if WRDE_APPEND and WRDE_REUSE are both specified.

The following constants are defined as error return values:

WRDE_BADCHAR — One of the unquoted characters ‡<newline>,`'|'`, `'&'`, `';'`, `'<'`, `'>'`, `'('`, `')'`, `'{'`, `'}'` ‡appears in *words* in an inappropriate context.

WRDE_BADVAL — Reference to undefined shell variable when WRDE_UNDEF is set in *flags*.

WRDE_CMDSUB — Command substitution requested when WRDE_NOCMD was set in *flags*.

WRDE_NOSPACE — Attempt to allocate memory failed.

WRDE_SYNTAX — Shell syntax error, such as unbalanced parentheses or unterminated string.

RETURN VALUE

Upon successful completion, *wordexp*( ) shall return 0. Otherwise, a non-zero value, as described in **<wordexp.h>**, shall be returned to indicate an error. If *wordexp*( ) returns the value WRDE_NOSPACE, then *pwordexp* ~~->~~*we_wordc* and *pwordexp* ~~->~~*we_wordv* shall be updated to reflect any words that were successfully expanded. In other error cases, if the WRDE_APPEND flag was specified, *pwordexp->we_wordc* and *pwordexp->we_wordv* shall not be modified.

The *wordfree*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The *wordexp*( ) function is intended to be used by an application that wants to do all of the shell's expansions on a word or words obtained from a user. For example, if the application prompts for a pathname (or list of pathnames) and then uses *wordexp*( ) to process the input, the user could respond with anything that would be valid as input to the shell.

The WRDE_NOCMD flag is provided for applications that, for security or other reasons, want to prevent a user from executing shell commands. Disallowing unquoted shell special characters also prevents unwanted side-effects, such as executing a command or writing a file.

POSIX.1-2017 does not require the *wordexp*( ) function to be thread-safe if passed an expression referencing an environment variable while any other thread is concurrently modifying any environment variable; see *exec* (on page 783).

Even though the WRDE_SHOWERR flag allows the implementation to write messages to *stderr* during command substitution or syntax errors, this standard does not provide any way to detect write failures during the output of such messages.

Applications which use wide-character output functions with *stderr* should ensure that any calls to *wordexp*( ) do not write to *stderr*, by avoiding use of the WRDE_SHOWERR flag.

RATIONALE

This function was included as an alternative to *glob*( ). There had been continuing controversy over exactly what features should be included in *glob*( ). It is hoped that by providing *wordexp*( ) (which provides all of the shell word expansions, but which may be slow to execute) and *glob*( ) (which is faster, but which only performs pathname expansion, without tilde or parameter expansion) this will satisfy the majority of applications.

While *wordexp*( ) could be implemented entirely as a library routine, it is expected that most implementations run a shell in a subprocess to do the expansion.

Two different approaches have been proposed for how the required information might be presented to the shell and the results returned. They are presented here as examples.

One proposal is to extend the *echo* utility by adding a **−q** option. This option would cause *echo* to add a <backslash> before each <backslash> and <blank> that occurs within an argument. The *wordexp*( ) function could then invoke the shell as follows:

```
(void) strcpy(buffer, "echo -q");
(void) strcat(buffer, words);
if ((flags & WRDE_SHOWERR) == 0)
    (void) strcat(buffer, "2>/dev/null");
f = popen(buffer, "r");
```

The *wordexp*( ) function would read the resulting output, remove unquoted <backslash> characters, and break into words at unquoted <blank> characters. If the WRDE_NOCMD flag was set, *wordexp*( ) would have to scan *words* before starting the subshell to make sure that there would be no command substitution. In any case, it would have to scan *words* for unquoted special characters.

Another proposal is to add the following options to *sh*:

−w *wordlist*
: This option provides a wordlist expansion service to applications. The words in *wordlist* shall be expanded and the following written to standard output:

  1. The count of the number of words after expansion, in decimal, followed by a null byte
  2. The number of bytes needed to represent the expanded words (not including null separators), in decimal, followed by a null byte
  3. The expanded words, each terminated by a null byte

  If an error is encountered during word expansion, *sh* exits with a non-zero status after writing the former to report any words successfully expanded

−P Run in ``protected'' mode. If specified with the **−w** option, no command substitution shall be performed.

With these options, *wordexp*( ) could be implemented fairly simply by creating a subprocess using *fork*( ) and executing *sh* using the line:

```
execl(<shell path>, "sh", "-P", "-w", words, (char *)0);
```

after directing standard error to **/dev/null**.

It seemed objectionable for a library routine to write messages to standard error, unless explicitly requested, so *wordexp*( ) is required to redirect standard error to **/dev/null** to ensure that no messages are generated, even for commands executed for command substitution. The WRDE_SHOWERR flag can be specified to request that error messages be written.

The WRDE_REUSE flag allows the implementation to avoid the expense of freeing and reallocating memory, if that is possible. A minimal implementation can call *wordfree*( ) when WRDE_REUSE is set.

FUTURE DIRECTIONS

None.

73430 **NAME**

73431 wprintf ‡'print formatted wide-character output

73432 **SYNOPSIS**

73433 `#include <stdio.h>`

73434 `#include <wchar.h>`

73435 `int wprintf(const wchar_t *restrict format, ...);`

73436 **DESCRIPTION**

73437 Refer to *fwprintf( )*.

73438 **NAME**

73439 pwrite, write ‡'write on a file

73440 **SYNOPSIS**

73441 ```
#include <unistd.h>
```

73442 ```
ssize_t pwrite(int fildes, const void *buf, size_t nbyte,
```

73443 ```
    off_t offset);
```

73444 ```
ssize_t write(int fildes, const void *buf, size_t nbyte);
```

73445 **DESCRIPTION**

73446 The *write*( ) function shall attempt to write *nbyte* bytes from the buffer pointed to by *buf* to the
73447 file associated with the open file descriptor, *fildes*.

73448 Before any action described below is taken, and if *nbyte* is zero and the file is a regular file, the
73449 *write*( ) function may detect and return errors as described below. In the absence of errors, or if
73450 error detection is not performed, the *write*( ) function shall return zero and have no other results.
73451 If *nbyte* is zero and the file is not a regular file, the results are unspecified.

73452 On a regular file or other file capable of seeking, the actual writing of data shall proceed from
73453 the position in the file indicated by the file offset associated with *fildes*. Before successful return
73454 from *write*( ), the file offset shall be incremented by the number of bytes actually written. On a
73455 regular file, if the position of the last byte written is greater than or equal to the length of the file,
73456 the length of the file shall be set to this position plus one.

73457 On a file not capable of seeking, writing shall always take place starting at the current position.
73458 The value of a file offset associated with such a device is undefined.

73459 If the O_APPEND flag of the file status flags is set, the file offset shall be set to the end of the file
73460 prior to each write and no intervening file modification operation shall occur between changing
73461 the file offset and the write operation.

73462 XSI If a *write*( ) requests that more bytes be written than there is room for (for example, the file size
73463 limit of the process or the physical end of a medium), only as many bytes as there is room for
73464 shall be written. For example, suppose there is space for 20 bytes more in a file before reaching a
73465 limit. A write of 512 bytes will return 20. The next write of a non-zero number of bytes would
73466 give a failure return (except as noted below).

73467 XSI If the request would cause the file size to exceed the soft file size limit for the process and there
73468 is no room for any bytes to be written, the request shall fail and the implementation shall
73469 generate the SIGXFSZ signal for the thread.

73470 If *write*( ) is interrupted by a signal before it writes any data, it shall return –1 with *errno* set to
73471 [EINTR].

73472 If *write*( ) is interrupted by a signal after it successfully writes some data, it shall return the
73473 number of bytes written.

73474 If the value of *nbyte* is greater than {SSIZE_MAX}, the result is implementation-defined.

73475 After a *write*( ) to a regular file has successfully returned:

73476 Any successful *read*( ) from each byte position in the file that was modified by that write
73477 shall return the data specified by the *write*( ) for that position until such byte positions are
73478 again modified.

73479 Any subsequent successful *write*( ) to the same byte position in the file shall overwrite that
73480 file data.

Write requests to a pipe or FIFO shall be handled in the same way as a regular file with the following exceptions:

There is no file offset associated with a pipe, hence each write request shall append to the end of the pipe.

Write requests of {PIPE_BUF} bytes or less shall not be interleaved with data from other processes doing writes on the same pipe. Writes of greater than {PIPE_BUF} bytes may have data interleaved, on arbitrary boundaries, with writes by other processes, whether or not the O_NONBLOCK flag of the file status flags is set.

If the O_NONBLOCK flag is clear, a write request may cause the thread to block, but on normal completion it shall return *nbyte*.

If the O_NONBLOCK flag is set, *write*( ) requests shall be handled differently, in the following ways:

- The *write*( ) function shall not block the thread.
- A write request for {PIPE_BUF} or fewer bytes shall have the following effect: if there is sufficient space available in the pipe, *write*( ) shall transfer all the data and return the number of bytes requested. Otherwise, *write*( ) shall transfer no data and return −1 with *errno* set to [EAGAIN].
- A write request for more than {PIPE_BUF} bytes shall cause one of the following:
  - When at least one byte can be written, transfer what it can and return the number of bytes written. When all data previously written to the pipe is read, it shall transfer at least {PIPE_BUF} bytes.
  - When no data can be written, transfer no data, and return −1 with *errno* set to [EAGAIN].

When attempting to write to a file descriptor (other than a pipe or FIFO) that supports non-blocking writes and cannot accept the data immediately:

If the O_NONBLOCK flag is clear, *write*( ) shall block the calling thread until the data can be accepted.

If the O_NONBLOCK flag is set, *write*( ) shall not block the thread. If some data can be written without blocking the thread, *write*( ) shall write what it can and return the number of bytes written. Otherwise, it shall return −1 and set *errno* to [EAGAIN].

Upon successful completion, where *nbyte* is greater than 0, *write*( ) shall mark for update the last data modification and last file status change timestamps of the file, and if the file is a regular file, the S_ISUID and S_ISGID bits of the file mode may be cleared.

For regular files, no data transfer shall occur past the offset maximum established in the open file description associated with *fildes*.

If *fildes* refers to a socket, *write*( ) shall be equivalent to *send*( ) with no flags set.

SIO If the O_DSYNC bit has been set, write I/O operations on the file descriptor shall complete as defined by synchronized I/O data integrity completion.

If the O_SYNC bit has been set, write I/O operations on the file descriptor shall complete as defined by synchronized I/O file integrity completion.

SHM If *fildes* refers to a shared memory object, the result of the *write*( ) function is unspecified.

TYM If *fildes* refers to a typed memory object, the result of the *write*( ) function is unspecified.

OB XSR If *fildes* refers to a STREAM, the operation of *write*( ) shall be determined by the values of the minimum and maximum *nbyte* range (packet size) accepted by the STREAM. These values are determined by the topmost STREAM module. If *nbyte* falls within the packet size range, *nbyte* bytes shall be written. If *nbyte* does not fall within the range and the minimum packet size value is 0, *write*( ) shall break the buffer into maximum packet size segments prior to sending the data downstream (the last segment may contain less than the maximum packet size). If *nbyte* does not fall within the range and the minimum value is non-zero, *write*( ) shall fail with *errno* set to [ERANGE]. Writing a zero-length buffer (*nbyte* is 0) to a STREAMS device sends 0 bytes with 0 returned. However, writing a zero-length buffer to a STREAMS-based pipe or FIFO sends no message and 0 is returned. The process may issue I_SWROPT *ioctl*( ) to enable zero-length messages to be sent across the pipe or FIFO.

When writing to a STREAM, data messages are created with a priority band of 0. When writing to a STREAM that is not a pipe or FIFO:

> If O_NONBLOCK is clear, and the STREAM cannot accept data (the STREAM write queue is full due to internal flow control conditions), *write*( ) shall block until data can be accepted.
>
> If O_NONBLOCK is set and the STREAM cannot accept data, *write*( ) shall return –1 and set *errno* to [EAGAIN].
>
> If O_NONBLOCK is set and part of the buffer has been written while a condition in which the STREAM cannot accept additional data occurs, *write*( ) shall terminate and return the number of bytes written.

In addition, *write*( ) shall fail if the STREAM head has processed an asynchronous error before the call. In this case, the value of *errno* does not reflect the result of *write*( ), but reflects the prior error.

The *pwrite*( ) function shall be equivalent to *write*( ), except that it writes into a given position and does not change the file offset (regardless of whether O_APPEND is set). The first three arguments to *pwrite*( ) are the same as *write*( ) with the addition of a fourth argument *offset* for the desired position inside the file. An attempt to perform a *pwrite*( ) on a file that is incapable of seeking shall result in an error.

RETURN VALUE

Upon successful completion, these functions shall return the number of bytes actually written to the file associated with *fildes*. This number shall never be greater than *nbyte*. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

These functions shall fail if:

[EAGAIN] The file is neither a pipe, nor a FIFO, nor a socket, the O_NONBLOCK flag is set for the file descriptor, and the thread would be delayed in the *write*( ) operation.

[EBADF] The *fildes* argument is not a valid file descriptor open for writing.

[EFBIG] An attempt was made to write a file that exceeds the implementation-defined maximum file size XSI or the file size limit of the process, and there was no room for any bytes to be written.

[EFBIG] The file is a regular file, *nbyte* is greater than 0, and the starting position is greater than or equal to the offset maximum established in the open file description associated with *fildes*.

[EINTR] The write operation was terminated due to the receipt of a signal, and no data was transferred.

[EIO] The process is a member of a background process group attempting to write to its controlling terminal, TOSTOP is set, the calling thread is not blocking SIGTTOU, the process is not ignoring SIGTTOU, and the process group of the process is orphaned. This error may also be returned under implementation-defined conditions.

[ENOSPC] There was no free space remaining on the device containing the file.

OB XSR [ERANGE] The transfer request size was outside the range supported by the STREAMS file associated with *fildes*.

The *pwrite*( ) function shall fail if:

[EINVAL] The file is a regular file or block special file, and the *offset* argument is negative. The file offset shall remain unchanged.

[ESPIPE] The file is incapable of seeking.

The *write*( ) function shall fail if:

[EAGAIN] The file is a pipe or FIFO, the O_NONBLOCK flag is set for the file descriptor, and the thread would be delayed in the write operation.

[EAGAIN] or [EWOULDBLOCK]
The file is a socket, the O_NONBLOCK flag is set for the file descriptor, and the thread would be delayed in the write operation.

[ECONNRESET] A write was attempted on a socket that is not connected.

[EPIPE] An attempt is made to write to a pipe or FIFO that is not open for reading by any process, or that only has one end open. A SIGPIPE signal shall also be sent to the thread.

[EPIPE] A write was attempted on a socket that is shut down for writing, or is no longer connected. In the latter case, if the socket is of type SOCK_STREAM, a SIGPIPE signal shall also be sent to the thread.

These functions may fail if:

OB XSR [EINVAL] The STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.

[EIO] A physical I/O error has occurred.

[ENOBUFS] Insufficient resources were available in the system to perform the operation.

[ENXIO] A request was made of a nonexistent device, or the request was outside the capabilities of the device.

OB XSR [ENXIO] A hangup occurred on the STREAM being written to.

OB XSR A write to a STREAMS file may fail if an error message has been received at the STREAM head. In this case, *errno* is set to the value included in the error message.

The *write*( ) function may fail if:

[EACCES] A write was attempted on a socket and the calling process does not have appropriate privileges.

[ENETDOWN] A write was attempted on a socket and the local network interface used to reach the destination is down.

[ENETUNREACH] A write was attempted on a socket and no route to the network is present.

EXAMPLES

Writing from a Buffer

The following example writes data from the buffer pointed to by *buf* to the file associated with the file descriptor *fd*.

```
#include <sys/types.h>
#include <string.h>
...
char buf[20];
size_t nbytes;
ssize_t bytes_written;
int fd;
...
strcpy(buf, "This is a test\n");
nbytes = strlen(buf);

bytes_written = write(fd, buf, nbytes);
...
```

APPLICATION USAGE

None.

RATIONALE

See also the RATIONALE section in *read*( ).

An attempt to write to a pipe or FIFO has several major characteristics:

Atomic/non-atomic: A write is atomic if the whole amount written in one operation is not interleaved with data from any other process. This is useful when there are multiple writers sending data to a single reader. Applications need to know how large a write request can be expected to be performed atomically. This maximum is called {PIPE_BUF}. This volume of POSIX.1-2017 does not say whether write requests for more than {PIPE_BUF} bytes are atomic, but requires that writes of {PIPE_BUF} or fewer bytes shall be atomic.

Blocking/immediate: Blocking is only possible with O_NONBLOCK clear. If there is enough space for all the data requested to be written immediately, the implementation should do so. Otherwise, the calling thread may block; that is, pause until enough space is available for writing. The effective size of a pipe or FIFO (the maximum amount that can be written in one operation without blocking) may vary dynamically, depending on the implementation, so it is not possible to specify a fixed value for it.

Complete/partial/deferred: A write request:

```
int fildes;
size_t nbyte;
```

```
ssize_t ret;
char *buf;

ret = write(fildes, buf, nbyte);
```

may return:

Complete *ret*=*nbyte*

Partial *ret*<*nbyte*

This shall never happen if *nbyte*≤{PIPE_BUF}. If it does happen (with *nbyte*>{PIPE_BUF}), this volume of POSIX.1-2017 does not guarantee atomicity, even if *ret*≤{PIPE_BUF}, because atomicity is guaranteed according to the amount *requested*, not the amount *written*.

Deferred: *ret*=–1, *errno*=[EAGAIN]

This error indicates that a later request may succeed. It does not indicate that it *shall* succeed, even if *nbyte*≤{PIPE_BUF}, because if no process reads from the pipe or FIFO, the write never succeeds. An application could usefully count the number of times [EAGAIN] is caused by a particular value of *nbyte*>{PIPE_BUF} and perhaps do later writes with a smaller value, on the assumption that the effective size of the pipe may have decreased.

Partial and deferred writes are only possible with O_NONBLOCK set.

The relations of these properties are shown in the following tables:

Write to a Pipe or FIFO with O_NONBLOCK *clear*			
Immediately Writable:	**None**	**Some**	*nbyte*
nbyte≤{PIPE_BUF}	Atomic blocking *nbyte*	Atomic blocking *nbyte*	Atomic immediate *nbyte*
nbyte>{PIPE_BUF}	Blocking *nbyte*	Blocking *nbyte*	Blocking *nbyte*

If the O_NONBLOCK flag is clear, a write request shall block if the amount writable immediately is less than that requested. If the flag is set (by *fcntl*( )), a write request shall never block.

Write to a Pipe or FIFO with O_NONBLOCK *set*			
Immediately Writable:	**None**	**Some**	*nbyte*
nbyte≤{PIPE_BUF}	–1, [EAGAIN]	–1, [EAGAIN]	Atomic *nbyte*
nbyte>{PIPE_BUF}	–1, [EAGAIN]	<*nbyte* or –1, [EAGAIN]	≤*nbyte* or –1, [EAGAIN]

There is no exception regarding partial writes when O_NONBLOCK is set. With the exception of writing to an empty pipe, this volume of POSIX.1-2017 does not specify exactly when a partial write is performed since that would require specifying internal details of the implementation. Every application should be prepared to handle partial writes when O_NONBLOCK is set and the requested amount is greater than {PIPE_BUF}, just as every application should be prepared to handle partial writes on other kinds of file descriptors.

The intent of forcing writing at least one byte if any can be written is to assure that each write makes progress if there is any room in the pipe. If the pipe is empty, {PIPE_BUF} bytes must be written; if not, at least some progress must have been made.

Where this volume of POSIX.1-2017 requires –1 to be returned and *errno* set to [EAGAIN], most

historical implementations return zero (with the O_NDELAY flag set, which is the historical predecessor of O_NONBLOCK, but is not itself in this volume of POSIX.1-2017). The error indications in this volume of POSIX.1-2017 were chosen so that an application can distinguish these cases from end-of-file. While *write*( ) cannot receive an indication of end-of-file, *read*( ) can, and the two functions have similar return values. Also, some existing systems (for example, Eighth Edition) permit a write of zero bytes to mean that the reader should get an end-of-file indication; for those systems, a return value of zero from *write*( ) indicates a successful write of an end-of-file indication.

Implementations are allowed, but not required, to perform error checking for *write*( ) requests of zero bytes.

The concept of a {PIPE_MAX} limit (indicating the maximum number of bytes that can be written to a pipe in a single operation) was considered, but rejected, because this concept would unnecessarily limit application writing.

See also the discussion of O_NONBLOCK in *read*( ).

Writes can be serialized with respect to other reads and writes. If a *read*( ) of file data can be proven (by any means) to occur after a *write*( ) of the data, it must reflect that *write*( ), even if the calls are made by different processes. A similar requirement applies to multiple write operations to the same file position. This is needed to guarantee the propagation of data from *write*( ) calls to subsequent *read*( ) calls. This requirement is particularly significant for networked file systems, where some caching schemes violate these semantics.

Note that this is specified in terms of *read*( ) and *write*( ). The XSI extensions *readv*( ) and *writev*( ) also obey these semantics. A new ``high-performance'' write analog that did not follow these serialization requirements would also be permitted by this wording. This volume of POSIX.1-2017 is also silent about any effects of application-level caching (such as that done by *stdio*).

This volume of POSIX.1-2017 does not specify the value of the file offset after an error is returned; there are too many cases. For programming errors, such as [EBADF], the concept is meaningless since no file is involved. For errors that are detected immediately, such as [EAGAIN], clearly the pointer should not change. After an interrupt or hardware error, however, an updated value would be very useful and is the behavior of many implementations.

This volume of POSIX.1-2017 does not specify the behavior of concurrent writes to a regular file from multiple threads, except that each write is atomic (see Section 2.9.7, on page 522). Applications should use some form of concurrency control.

This volume of POSIX.1-2017 intentionally does not specify any *pwrite*( ) errors related to pipes, FIFOs, and sockets other than [ESPIPE].

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

The *pwrite*( ) function is added.

Issue 6

The DESCRIPTION states that the *write*( ) function does not block the thread. Previously this said ``process'' rather than ``thread''.

The DESCRIPTION and ERRORS sections are updated so that references to STREAMS are marked as part of the XSI STREAMS Option Group.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION now states that if *write*( ) is interrupted by a signal after it has successfully written some data, it returns the number of bytes written. In the POSIX.1-1988 standard, it was optional whether *write*( ) returned the number of bytes written, or whether it returned –1 with *errno* set to [EINTR]. This is a FIPS requirement.

- The following changes are made to support large files:

  - ‡ For regular files, no data transfer occurs past the offset maximum established in the open file description associated with the *fildes*.

  - ‡ A second [EFBIG] error condition is added.

- The [EIO] error condition is added.

- The [EPIPE] error condition is added for when a pipe has only one end open.

- The [ENXIO] optional error condition is added.

Text referring to sockets is added to the DESCRIPTION.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effect of reading zero bytes is clarified.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that *write*( ) results are unspecified for typed memory objects.

The following error conditions are added for operations on sockets: [EAGAIN], [EWOULDBLOCK], [ECONNRESET], [ENOTCONN], and [EPIPE].

The [EIO] error is made optional.

The [ENOBUFS] error is added for sockets.

The following error conditions are added for operations on sockets: [EACCES], [ENETDOWN], and [ENETUNREACH].

The *writev*( ) function is split out into a separate reference page.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/146 is applied, updating text in the ERRORS section from ``a SIGPIPE signal is generated to the calling process'' to ``a SIGPIPE signal shall also be sent to the thread''.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/147 is applied, making a correction to the RATIONALE.

Issue 7

The *pwrite*( ) function is moved from the XSI option to the Base.

Functionality relating to the XSI STREAMS option is marked obsolescent.

SD5-XSH-ERN-160 is applied, updating the DESCRIPTION to clarify the requirements for the *pwrite*( ) function, and to change the use of the phrase ``file pointer'' to ``file offset''.

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0742 [219], XSH/TC1-2008/0743 [215], XSH/TC1-2008/0744 [79], and XSH/TC1-2008/0745 [215] are applied.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0401 [676,710] and XSH/TC2-2008/0402 [966] are applied.

NAME

writev ‡'write a vector

SYNOPSIS

XSI
```
#include <sys/uio.h>

ssize_t writev(int fildes, const struct iovec *iov, int iovcnt);
```

DESCRIPTION

The *writev*( ) function shall be equivalent to *write*( ), except as described below. The *writev*( ) function shall gather output data from the *iovcnt* buffers specified by the members of the *iov* array: *iov*[0], *iov*[1], ..., *iov*[*iovcnt*–1]. The *iovcnt* argument is valid if greater than 0 and less than or equal to {IOV_MAX}, as defined in **<limits.h>**.

Each *iovec* entry specifies the base address and length of an area in memory from which data should be written. The *writev*( ) function shall always write a complete area before proceeding to the next.

If *fildes* refers to a regular file and all of the *iov_len* members in the array pointed to by *iov* are 0, *writev*( ) shall return 0 and have no other effect. For other file types, the behavior is unspecified.

If the sum of the *iov_len* values is greater than {SSIZE_MAX}, the operation shall fail and no data shall be transferred.

RETURN VALUE

Upon successful completion, *writev*( ) shall return the number of bytes actually written. Otherwise, it shall return a value of –1, the file-pointer shall remain unchanged, and *errno* shall be set to indicate an error.

ERRORS

Refer to *write*( ).

In addition, the *writev*( ) function shall fail if:

[EINVAL] The sum of the *iov_len* values in the *iov* array would overflow an **ssize_t**.

The *writev*( ) function may fail and set *errno* to:

[EINVAL] The *iovcnt* argument was less than or equal to 0, or greater than {IOV_MAX}.

EXAMPLES

Writing Data from an Array

The following example writes data from the buffers specified by members of the *iov* array to the file associated with the file descriptor *fd*.

```
#include <sys/types.h>
#include <sys/uio.h>
#include <unistd.h>
...
ssize_t bytes_written;
int fd;
char *buf0 = "short string\n";
char *buf1 = "This is a longer string\n";
char *buf2 = "This is the longest string in this example\n";
int iovcnt;
struct iovec iov[3];
```

```
        iov[0].iov_base = buf0;
        iov[0].iov_len = strlen(buf0);
        iov[1].iov_base = buf1;
        iov[1].iov_len = strlen(buf1);
        iov[2].iov_base = buf2;
        iov[2].iov_len = strlen(buf2);
        ...
        iovcnt = sizeof(iov) / sizeof(struct iovec);
        bytes_written = writev(fd, iov, iovcnt);
        ...
```

APPLICATION USAGE

None.

RATIONALE

Refer to *write( )*.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 6

Split out from the *write( )* reference page.

73847 **NAME**

73848 wscanf ‡'convert formatted wide-character input

73849 **SYNOPSIS**

73850 `#include <stdio.h>`

73851 `#include <wchar.h>`

73852 `int wscanf(const wchar_t *restrict format, ...);`

73853 **DESCRIPTION**

73854 Refer to *fwscanf( )*.

73855 **NAME**

73856 y0, y1, yn ‡Bessel functions of the second kind

73857 **SYNOPSIS**

73858 XSI
```
#include <math.h>

double y0(double x);
double y1(double x);
double yn(int n, double x);
```

73862 **DESCRIPTION**

73863 The *y0*(), *y1*(), and *yn*() functions shall compute Bessel functions of *x* of the second kind of
73864 orders 0, 1, and *n*, respectively.

73865 An application wishing to check for error situations should set *errno* to zero and call
73866 *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or
73867 *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-
73868 zero, an error has occurred.

73869 **RETURN VALUE**

73870 Upon successful completion, these functions shall return the relevant Bessel value of *x* of the
73871 second kind.

73872 MXX If *x* is NaN, NaN shall be returned.

73873 If the *x* argument to these functions is negative, –HUGE_VAL or NaN shall be returned, and a
73874 domain error may occur.

73875 If *x* is 0.0, –HUGE_VAL shall be returned and a pole error may occur.

73876 If the correct result would cause underflow, 0.0 shall be returned and a range error may occur.

73877 If the correct result would cause overflow, –HUGE_VAL or 0.0 shall be returned and a range
73878 error may occur.

73879 **ERRORS**

73880 These functions may fail if:

73881 Domain Error The value of *x* is negative.

73882 If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero,
73883 then *errno* shall be set to [EDOM]. If the integer expression (*math_errhandling*
73884 & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception
73885 shall be raised.

73886 Pole Error The value of *x* is zero.

73887 If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero,
73888 then *errno* shall be set to [ERANGE]. If the integer expression
73889 (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the divide-by-zero
73890 floating-point exception shall be raised.

73891 Range Error The correct result would cause overflow.

73892 If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero,
73893 then *errno* shall be set to [ERANGE]. If the integer expression
73894 (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the overflow
73895 floating-point exception shall be raised.

Range Error — The value of *x* is too large in magnitude, or the correct result would cause underflow.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (*math_errhandling* & MATH_ERRNO) and (*math_errhandling* & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD Section 4.20 (on page 117), **<math.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The normative text is updated to avoid use of the term ``must'' for application requirements.

The RETURN VALUE and ERRORS sections are reworked for alignment of the error handling with the ISO/IEC 9899: 1999 standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/148 is applied, updating the RETURN VALUE and ERRORS sections. The changes are made for consistency with the general rules stated in ``Treatment of Error Conditions for Mathematical Functions'' in the Base Definitions volume of POSIX.1-2017.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XSH/TC1-2008/0746 [68] is applied.

Open Group Standard

Vol. 3:

Shell and Utilities, Issue 7

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Chapter 1 Introduction

The Shell and Utilities volume of POSIX.1-2017 describes the commands and utilities offered to application programs by POSIX-conformant systems.

1.1 Relationship to Other Documents

1.1.1 System Interfaces

This subsection describes some of the features provided by the System Interfaces volume of POSIX.1-2017 that are assumed to be globally available on all systems conforming to this volume of POSIX.1-2017. This subsection does not attempt to detail all of the features defined in the System Interfaces volume of POSIX.1-2017 that are required by all of the utilities defined in this volume of POSIX.1-2017; the utility and function descriptions point out additional functionality required to provide the corresponding specific features needed by each.

The following subsections describe frequently used concepts. Many of these concepts are described in the Base Definitions volume of POSIX.1-2017. Utility and function description statements override these defaults when appropriate.

1.1.1.1 Process Attributes

The following process attributes, as described in the System Interfaces volume of POSIX.1-2017, are assumed to be supported for all processes in this volume of POSIX.1-2017:

Controlling Terminal	Real Group ID
Current Working Directory	Real User ID
Effective Group ID	Root Directory
Effective User ID	Saved Set-Group-ID
File Descriptors	Saved Set-User-ID
File Mode Creation Mask	Session Membership
Process Group ID	Supplementary Group IDs
Process ID	

A conforming implementation may include additional process attributes.

1.1.1.2 Concurrent Execution of Processes

The following functionality of the *fork*() function defined in the System Interfaces volume of POSIX.1-2017 shall be available on all systems conforming to this volume of POSIX.1-2017:

1. Independent processes shall be capable of executing independently without either process terminating.

2. A process shall be able to create a new process with all of the attributes referenced in Section 1.1.1.1 (on page 2327), determined according to the semantics of a call to the *fork*( ) function defined in the System Interfaces volume of POSIX.1-2017 followed by a call in the child process to one of the *exec* functions defined in the System Interfaces volume of POSIX.1-2017.

1.1.1.3 *File Access Permissions*

The file access control mechanism described by XBD Section 4.5 (on page 108) shall apply to all files on an implementation conforming to this volume of POSIX.1-2017.

1.1.1.4 *File Read, Write, and Creation*

If a file that does not exist is to be written, it shall be created as described below, unless the utility description states otherwise.

When a file that does not exist is created, the following features defined in the System Interfaces volume of POSIX.1-2017 shall apply unless the utility or function description states otherwise:

1. The user ID of the file shall be set to the effective user ID of the calling process.
2. The group ID of the file shall be set to the effective group ID of the calling process or the group ID of the directory in which the file is being created.
3. If the file is a regular file, the permission bits of the file shall be set to:

   S_IROTH | S_IWOTH | S_IRGRP | S_IWGRP | S_IRUSR | S_IWUSR

   (see the description of *File Modes* in XBD Chapter 13 (on page 219), **<sys/stat.h>**) except that the bits specified by the file mode creation mask of the process shall be cleared. If the file is a directory, the permission bits shall be set to:

   S_IRWXU | S_IRWXG | S_IRWXO

   except that the bits specified by the file mode creation mask of the process shall be cleared.
4. The last data access, last data modification, and last file status change timestamps of the file shall be updated as specified in XBD Section 4.9 (on page 109).
5. If the file is a directory, it shall be an empty directory; otherwise, the file shall have length zero.
6. If the file is a symbolic link, the effect shall be undefined unless the {POSIX2_SYMLINKS} variable is in effect for the directory in which the symbolic link would be created.
7. Unless otherwise specified, the file created shall be a regular file.

When an attempt is made to create a file that already exists, the utility shall take the action indicated in Table 1-1 (on page 2329) corresponding to the type of the file the utility is trying to create and the type of the existing file, unless the utility description states otherwise.

Table 1-1 Actions when Creating a File that Already Exists

Existing Type	New Type B	C	D	F	L	M	P	Q	R	S	T	Function Creating New
A *fattach*()-ed STREAM	F	F	F	F	F		‡	–	’	—	OF	—	U	N/A
B Block Special	F	F	F	F	F	U	U	U	OF	U	U	*mknod*()**
C Character Special	F	F	F	F	F	U	U	U	OF	U	U	*mknod*()**
D Directory	F	F	F	F	F		‡	’	‡	’	‡	’	F	*mkdir*()U
F FIFO Special File	F	F	F	F	F		‡	’	‡	’	‡	’	O	*mkfifo*()U
L Symbolic Link	F	F	F	F	F		‡	’	‡	’	L	‡	’	FU	’*symlink*()
M Shared Memory	F	F	F	F	F		‡	’	‡	’	‡	’		*shm_open*()U
P Semaphore	F	F	F	F	F		‡	’	‡	’	‡	’		*sem_open*()U
Q Message Queue	F	F	F	F	F		‡	’	‡	’	‡	’		*mq_open*()U
R Regular File	F	F	F	F	F		‡	’	‡	’	F	‡	’	RU	’*open*()
S Socket	F	F	F	F	F		‡	’	‡	’	‡	’		*bind*() ‡ ’U
T Typed Memory	F	F	F	F	F	U	U	U	U	U	U	*

The following codes are used in Table 1-1:

F Fail. The attempt to create the new file shall fail and the utility shall either continue with its operation or exit immediately with a non-zero exit status, depending on the description of the utility.

FL Follow link. Unless otherwise specified, the symbolic link shall be followed as specified for pathname resolution, and the operation performed shall be as if the target of the symbolic link (after all resolution) had been named. If the target of the symbolic link does not exist, it shall be as if that nonexistent target had been named directly.

O Open FIFO. When attempting to create a regular file, and the existing file is a FIFO special file:

1. If the FIFO is not already open for reading, the attempt shall block until the FIFO is opened for reading.
2. Once the FIFO is open for reading, the utility shall open the FIFO for writing and continue with its operation.

OF The named file shall be opened with the consequences defined for that file type.

RF Regular file. When attempting to create a regular file, and the existing file is a regular file:

1. The user ID, group ID, and permission bits of the file shall not be changed.
2. The file shall be truncated to zero length.
3. The last data modification and last file status change timestamps shall be marked for update.

‡ The effect is implementation-defined unless specified by the utility description.

U The effect is unspecified unless specified by the utility description.

* There is no portable way to create a file of this type.

** Not portable.

When a file is to be appended, the file shall be opened in a manner equivalent to using the O_APPEND flag, without the O_TRUNC flag, in the *open*() function defined in the System Interfaces volume of POSIX.1-2017.

When a file is to be read or written, the file shall be opened with an access mode corresponding to the operation to be performed. If file access permissions deny access, the requested operation shall fail.

1.1.1.5 *File Removal*

When a directory that is the root directory or current working directory of any process is removed, the effect is implementation-defined. If file access permissions deny access, the requested operation shall fail. Otherwise, when a file is removed:

1. Its directory entry shall be removed from the file system.
2. The link count of the file shall be decremented.
3. If the file is an empty directory (see XBD Section 3.144, on page 56):
    a. If no process has the directory open, the space occupied by the directory shall be freed and the directory shall no longer be accessible.
    b. If one or more processes have the directory open, the directory contents shall be preserved until all references to the file have been closed.
4. If the file is a directory that is not empty, the last file status change timestamp shall be marked for update.
5. If the file is not a directory:
    a. If the link count becomes zero:
        i. If no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible.
        ii. If one or more processes have the file open, the file contents shall be preserved until all references to the file have been closed.
    b. If the link count is not reduced to zero, the last file status change timestamp shall be marked for update.
6. The last data modification and last file status change timestamps of the containing directory shall be marked for update.

1.1.1.6 *File Time Values*

All files shall have the three time values described by XBD Section 4.9 (on page 109).

1.1.1.7 *File Contents*

When a reference is made to the contents of a file, *pathname*, this means the equivalent of all of the data placed in the space pointed to by *buf* when performing the *read*( ) function calls in the following operations defined in the System Interfaces volume of POSIX.1-2017:

```
while (read (fildes, buf, nbytes) > 0)
    ;
```

If the file is indicated by a pathname *pathname*, the file descriptor shall be determined by the equivalent of the following operation defined in the System Interfaces volume of POSIX.1-2017:

```
fildes = open (pathname, O_RDONLY);
```

The value of *nbytes* in the above sequence is unspecified; if the file is of a type where the data

returned by *read*() would vary with different values, the value shall be one that results in the most data being returned.

If the *read*() function calls would return an error, it is unspecified whether the contents of the file are considered to include any data from offsets in the file beyond where the error would be returned.

1.1.1.8 *Pathname Resolution*

The pathname resolution algorithm, described by XBD Section 4.13 (on page 111), shall be used by implementations conforming to this volume of POSIX.1-2017; see also XBD Section 4.6 (on page 109).

1.1.1.9 *Changing the Current Working Directory*

When the current working directory (see XBD Section 3.122, on page 53) is to be changed, unless the utility or function description states otherwise, the operation shall succeed unless a call to the *chdir*() function defined in the System Interfaces volume of POSIX.1-2017 would fail when invoked with the new working directory pathname as its argument.

1.1.1.10 *Establish the Locale*

The functionality of the *setlocale*() function defined in the System Interfaces volume of POSIX.1-2017 shall be available on all systems conforming to this volume of POSIX.1-2017; that is, utilities that require the capability of establishing an international operating environment shall be permitted to set the specified category of the international environment.

1.1.1.11 *Actions Equivalent to Functions*

Some utility descriptions specify that a utility performs actions equivalent to a function defined in the System Interfaces volume of POSIX.1-2017. Such specifications require only that the external effects be equivalent, not that any effect within the utility and visible only to the utility be equivalent.

1.1.2 Concepts Derived from the ISO C Standard

Some of the standard utilities perform complex data manipulation using their own procedure and arithmetic languages, as defined in their EXTENDED DESCRIPTION or OPERANDS sections. Unless otherwise noted, the arithmetic and semantic concepts (precision, type conversion, control flow, and so on) shall be equivalent to those defined in the ISO C standard, as described in the following sections. Note that there is no requirement that the standard utilities be implemented in any particular programming language.

1.1.2.1 *Arithmetic Precision and Operations*

Integer variables and constants, including the values of operands and option-arguments, used by the standard utilities listed in this volume of POSIX.1-2017 shall be implemented as equivalent to the ISO C standard **signed long** data type; floating point shall be implemented as equivalent to the ISO C standard **double** type. Conversions between types shall be as described in the ISO C standard. All variables shall be initialized to zero if they are not otherwise assigned by the input to the application.

Arithmetic operators and control flow keywords shall be implemented as equivalent to those in the cited ISO C standard section, as listed in Table 1-2.

Table 1-2 Selected ISO C Standard Operators and Control Flow Keywords

Operation	ISO C Standard Equivalent Reference
( )	Section 6.5.1, Primary Expressions
postfix ++ postfix --	Section 6.5.2, Postfix Operators
unary + unary - prefix ++ prefix -- ~ ! *sizeof*( )	Section 6.5.3, Unary Operators
* / %	Section 6.5.5, Multiplicative Operators
+ -	Section 6.5.6, Additive Operators
<< >>	Section 6.5.7, Bitwise Shift Operators
<, <= >, >=	Section 6.5.8, Relational Operators
= = !=	Section 6.5.9, Equality Operators
&	Section 6.5.10, Bitwise AND Operator
^	Section 6.5.11, Bitwise Exclusive OR Operator
|	Section 6.5.12, Bitwise Inclusive OR Operator
&&	Section 6.5.13, Logical AND Operator
| |	Section 6.5.14, Logical OR Operator
expr?*expr*:*expr*	Section 6.5.15, Conditional Operator
=, *=, /=, %=, +=, -= <<=, >>=, &=, ^=, |=	Section 6.5.16, Assignment Operators
if ( ) **if** ( ) ... **else** **switch** ( )	Section 6.8.4, Selection Statements
while ( ) **do** ... **while** ( ) **for** ( )	Section 6.8.5, Iteration Statements
goto **continue** **break** **return**	Section 6.8.6, Jump Statements

The evaluation of arithmetic expressions shall be equivalent to that described in Section 6.5, Expressions, of the ISO C standard.

1.1.2.2 *Mathematical Functions*

Any mathematical functions with the same names as those in the following sections of the ISO C standard:

Section 7.12, Mathematics, `<math.h>`

Section 7.20.2, Pseudo-Random Sequence Generation Functions

shall be implemented to return the results equivalent to those returned from a call to the corresponding function described in the ISO C standard.

1.2 Utility Limits

This section lists magnitude limitations imposed by a specific implementation. The braces notation, {LIMIT}, is used in this volume of POSIX.1-2017 to indicate these values, but the braces are not part of the name.

Table 1-3 Utility Limit Minimum Values

Name	Description	Value
{POSIX2_BC_BASE_MAX}	The maximum *obase* value allowed by the *bc* utility.	99
{POSIX2_BC_DIM_MAX}	The maximum number of elements permitted in an array by the *bc* utility.	2 048
{POSIX2_BC_SCALE_MAX}	The maximum *scale* value allowed by the *bc* utility.	99
{POSIX2_BC_STRING_MAX}	The maximum length of a string constant accepted by the *bc* utility.	1 000
{POSIX2_COLL_WEIGHTS_MAX}	The maximum number of weights that can be assigned to an entry of the *LC_COLLATE* **order** keyword in the locale definition file; see the **border_start** keyword in XBD Section 7.3.2 (on page 147).	2
{POSIX2_EXPR_NEST_MAX}	The maximum number of expressions that can be nested within parentheses by the *expr* utility.	32
{POSIX2_LINE_MAX}	Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>.	2 048
{POSIX_RE_DUP_MAX}	Maximum number of repeated occurrences of a BRE or ERE interval expression; see XBD Section 9.3.6 (on page 186) and Section 9.4.6 (on page 190).	255

The values specified in Table 1-3 represent the lowest values conforming implementations shall provide and, consequently, the largest values on which an application can rely without further

enquiries, as described below. These values shall be accessible to applications via the *getconf* utility (see *getconf*, on page 2831).

Implementations may provide more liberal, or less restrictive, values than shown in Table 1-3 (on page 2333). These possibly more liberal values are accessible using the symbols in Table 1-4.

The *sysconf*( ) function defined in the System Interfaces volume of POSIX.1-2017 or the *getconf* utility return the value of each symbol on each specific implementation. The value so retrieved is the largest, or most liberal, value that is available throughout the session lifetime, as determined at session creation. The literal names shown in the table apply only to the *getconf* utility; the high-level language binding describes the exact form of each name to be used by the interfaces in that binding.

All numeric limits defined by the System Interfaces volume of POSIX.1-2017, such as {PATH_MAX}, shall also apply to this volume of POSIX.1-2017. All the utilities defined by this volume of POSIX.1-2017 are implicitly limited by these values, unless otherwise noted in the utility descriptions.

It is not guaranteed that the application can actually reach the specified limit of an implementation in any given case, or at all, as a lack of virtual memory or other resources may prevent this. The limit value indicates only that the implementation does not specifically impose any arbitrary, more restrictive limit.

Table 1-4 Symbolic Utility Limits

Name	Description	Minimum Value
{BC_BASE_MAX}	The maximum *obase* value allowed by the *bc* utility.	{POSIX2_BC_BASE_MAX}
{BC_DIM_MAX}	The maximum number of elements permitted in an array by the *bc* utility.	{POSIX2_BC_DIM_MAX}
{BC_SCALE_MAX}	The maximum *scale* value allowed by the *bc* utility.	{POSIX2_BC_SCALE_MAX}
{BC_STRING_MAX}	The maximum length of a string constant accepted by the *bc* utility.	{POSIX2_BC_STRING_MAX}
{COLL_WEIGHTS_MAX}	The maximum number of weights that can be assigned to an entry of the *LC_COLLATE* **order** keyword in the locale definition file; see the **order_start** keyword in XBD Section 7.3.2 (on page 147).	{POSIX2_COLL_WEIGHTS_MAX}
{EXPR_NEST_MAX}	The maximum number of expressions that can be nested within parentheses by the *expr* utility.	{POSIX2_EXPR_NEST_MAX}

Name	Description	Minimum Value
{LINE_MAX}	Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>.	{POSIX2_LINE_MAX}
{RE_DUP_MAX}	Maximum number of repeated occurrences of a BRE or ERE interval expression; see XBD Section 9.3.6 (on page 186) and Section 9.4.6 (on page 190).	{POSIX_RE_DUP_MAX}

The following value may be a constant within an implementation or may vary from one pathname to another.

{POSIX2_SYMLINKS}
When referring to a directory, the system supports the creation of symbolic links within that directory; for non-directory files, the meaning of {POSIX2_SYMLINKS} is undefined.

1.3 Grammar Conventions

Portions of this volume of POSIX.1-2017 are expressed in terms of a special grammar notation. It is used to portray the complex syntax of certain program input. The grammar is based on the syntax used by the *yacc* utility. However, it does not represent fully functional *yacc* input, suitable for program use; the lexical processing and all semantic requirements are described only in textual form. The grammar is not based on source used in any traditional implementation and has not been tested with the semantic code that would normally be required to accompany it. Furthermore, there is no implication that the partial *yacc* code presented represents the most efficient, or only, means of supporting the complex syntax within the utility. Implementations may use other programming languages or algorithms, as long as the syntax supported is the same as that represented by the grammar.

The following typographical conventions are used in the grammar; they have no significance except to aid in reading.

The identifiers for the reserved words of the language are shown with a leading capital letter. (These are terminals in the grammar; for example, **While**, **Case**.)

The identifiers for terminals in the grammar are all named with uppercase letters and underscores; for example, **NEWLINE**, **ASSIGN_OP**, **NAME**.

The identifiers for non-terminals are all lowercase.

1.4 Utility Description Defaults

This section describes all of the subsections used within the utility descriptions, including:

Intended usage of the section

Global defaults that affect all the standard utilities

The meanings of notations used in this volume of POSIX.1-2017 that are specific to individual utility sections

NAME

This section gives the name or names of the utility and briefly states its purpose.

SYNOPSIS

The SYNOPSIS section summarizes the syntax of the calling sequence for the utility, including options, option-arguments, and operands. Standards for utility naming are described in XBD Section 12.2 (on page 216); for describing the utility's arguments in XBD Section 12.1 (on page 213).

DESCRIPTION

The DESCRIPTION section describes the actions of the utility. If the utility has a very complex set of subcommands or its own procedural language, an EXTENDED DESCRIPTION section is also provided. Most explanations of optional functionality are omitted here, as they are usually explained in the OPTIONS section.

As stated in Section 1.1.1.11 (on page 2331), some functions are described in terms of equivalent functionality. When specific functions are cited, the implementation shall provide equivalent functionality including side-effects associated with successful execution of the function. The treatment of errors and intermediate results from the individual functions cited is generally not specified by this volume of POSIX.1-2017. See the utility's EXIT STATUS and CONSEQUENCES OF ERRORS sections for all actions associated with errors encountered by the utility.

OPTIONS

The OPTIONS section describes the utility options and option-arguments, and how they modify the actions of the utility. Standard utilities that have options either fully comply with XBD Section 12.2 (on page 216) or describe all deviations. Apparent disagreements between functionality descriptions in the OPTIONS and DESCRIPTION (or EXTENDED DESCRIPTION) sections are always resolved in favor of the OPTIONS section.

Each OPTIONS section that uses the phrase ``The ... utility shall conform to the Utility Syntax Guidelines ...'' refers only to the use of the utility as specified by this volume of POSIX.1-2017; implementation extensions should also conform to the guidelines, but may allow exceptions for historical practice.

Unless otherwise stated in the utility description, when given an option unrecognized by the implementation, or when a required option-argument is not provided, standard utilities shall issue a diagnostic message to standard error and exit with a non-zero exit status.

All utilities in this volume of POSIX.1-2017 shall be capable of processing arguments using eight-bit transparency.

Default Behavior: When this section is listed as ``None.'', it means that the implementation need not support any options. Standard utilities that do not accept options, but that do accept operands, shall recognize `"--"` as a first argument to be discarded.

74329 The requirement for recognizing `"--"` is because conforming applications need a way
74330 to shield their operands from any arbitrary options that the implementation may
74331 provide as an extension. For example, if the standard utility *foo* is listed as taking no
74332 options, and the application needed to give it a pathname with a leading <hyphen-
74333 minus>, it could safely do it as:

74334 ```
foo -- -myfile
```

74335 and avoid any problems with −**m** used as an extension.

74336 **OPERANDS**

74337 The OPERANDS section describes the utility operands, and how they affect the actions
74338 of the utility. Apparent disagreements between functionality descriptions in the
74339 OPERANDS and DESCRIPTION (or EXTENDED DESCRIPTION) sections shall be
74340 resolved in favor of the OPERANDS section.

74341 If an operand naming a file can be specified as `'-'`, which means to use the standard
74342 input instead of a named file, this is explicitly stated in this section. Unless otherwise
74343 stated, the use of multiple instances of `'-'` to mean standard input in a single
74344 command produces unspecified results.

74345 Unless otherwise stated, the standard utilities that accept operands shall process those
74346 operands in the order specified in the command line.

74347 **Default Behavior:** When this section is listed as ``None.'', it means that the
74348 implementation need not support any operands.

74349 **STDIN**

74350 The STDIN section describes the standard input of the utility. This section is frequently
74351 merely a reference to the following section, as many utilities treat standard input and
74352 input files in the same manner. Unless otherwise stated, all restrictions described in the
74353 INPUT FILES section shall apply to this section as well.

74354 Use of a terminal for standard input can cause any of the standard utilities that read
74355 standard input to stop when used in the background. For this reason, applications
74356 should not use interactive features in scripts to be placed in the background.

74357 The specified standard input format of the standard utilities shall not depend on the
74358 existence or value of the environment variables defined in this volume of POSIX.1-2017,
74359 except as provided by this volume of POSIX.1-2017.

74360 **Default Behavior:** When this section is listed as ``Not used.'', it means that the standard
74361 input shall not be read when the utility is used as described by this volume of
74362 POSIX.1-2017.

74363 **INPUT FILES**

74364 The INPUT FILES section describes the files, other than the standard input, used as
74365 input by the utility. It includes files named as operands and option-arguments as well
74366 as other files that are referred to, such as start-up and initialization files, databases, and
74367 so on. Commonly-used files are generally described in one place and cross-referenced
74368 by other utilities.

74369 All utilities in this volume of POSIX.1-2017 shall be capable of processing input files
74370 using eight-bit transparency.

74371 When a standard utility reads a seekable input file and terminates without an error
74372 before it reaches end-of-file, the utility shall ensure that the file offset in the open file
74373 description is properly positioned just past the last byte processed by the utility. For
74374 files that are not seekable, the state of the file offset in the open file description for that

  
```

file is unspecified. A conforming application shall not assume that the following three commands are equivalent:

```
tail −n +2 file
(sed −n 1q; cat) < file
cat file | (sed −n 1q; cat)
```

The second command is equivalent to the first only when the file is seekable. The third command leaves the file offset in the open file description in an unspecified state. Other utilities, such as *head*, *read*, and *sh*, have similar properties.

Some of the standard utilities, such as filters, process input files a line or a block at a time and have no restrictions on the maximum input file size. Some utilities may have size limitations that are not as obvious as file space or memory limitations. Such limitations should reflect resource limitations of some sort, not arbitrary limits set by implementors. Implementations shall document those utilities that are limited by constraints other than file system space, available memory, and other limits specifically cited by this volume of POSIX.1-2017, and identify what the constraint is and indicate a way of estimating when the constraint would be reached. Similarly, some utilities descend the directory tree (recursively). Implementations shall also document any limits that they may have in descending the directory tree that are beyond limits cited by this volume of POSIX.1-2017.

When an input file is described as a ``text file'', the utility produces undefined results if given input that is not from a text file, unless otherwise stated. Some utilities (for example, *make*, *read*, *sh*) allow for continued input lines using an escaped <newline> convention; unless otherwise stated, the utility need not be able to accumulate more than {LINE_MAX} bytes from a set of multiple, continued input lines. Thus, for a conforming application the total of all the continued lines in a set cannot exceed {LINE_MAX}. If a utility using the escaped <newline> convention detects an end-of-file condition immediately after an escaped <newline>, the results are unspecified.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ). See XBD Chapter 5 (on page 121) for a description of this notation. The format description is intended to be sufficiently rigorous to allow other applications to generate these input files. However, since <blank>s can legitimately be included in some of the fields described by the standard utilities, particularly in locales other than the POSIX locale, this intent is not always realized.

Default Behavior: When this section is listed as ``None.'', it means that no input files are required to be supplied when the utility is used as described by this volume of POSIX.1-2017.

ENVIRONMENT VARIABLES

The ENVIRONMENT VARIABLES section lists what variables affect the utility's execution.

The entire manner in which environment variables described in this volume of POSIX.1-2017 affect the behavior of each utility is described in the ENVIRONMENT VARIABLES section for that utility, in conjunction with the global effects of the *LANG*, *LC_ALL*, and *NLSPATH* environment variables described in XBD Chapter 8 (on page 173). The existence or value of environment variables described in this volume of POSIX.1-2017 shall not otherwise affect the specified behavior of the standard utilities. Any effects of the existence or value of environment variables not described by this volume of POSIX.1-2017 upon the standard utilities are unspecified.

XSI

For those standard utilities that use environment variables as a means for selecting a

utility to execute (such as *CC* in *make*), the string provided to the utility is subjected to the path search described for *PATH* in XBD Chapter 8 (on page 173).

All utilities in this volume of POSIX.1-2017 shall be capable of processing environment variable names and values using eight-bit transparency.

Default Behavior: When this section is listed as ``None.'', it means that the behavior of the utility is not directly affected by environment variables described by this volume of POSIX.1-2017 when the utility is used as described by this volume of POSIX.1-2017.

ASYNCHRONOUS EVENTS

The ASYNCHRONOUS EVENTS section lists how the utility reacts to such events as signals and what signals are caught.

Default Behavior: When this section is listed as ``Default.'', or it refers to ``the standard action for all other signals; see Section 1.4 (on page 2336)'' it means that the action taken as a result of the signal shall be one of the following:

1. The action shall be that inherited from the parent according to the rules of inheritance of signal actions defined in the System Interfaces volume of POSIX.1-2017.
2. When no action has been taken to change the default, the default action shall be that specified by the System Interfaces volume of POSIX.1-2017.
3. The result of the utility's execution is as if default actions had been taken.

A utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

STDOUT

The STDOUT section completely describes the standard output of the utility. This section is frequently merely a reference to the following section, OUTPUT FILES, because many utilities treat standard output and output files in the same manner.

Use of a terminal for standard output may cause any of the standard utilities that write standard output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ). See XBD Chapter 5 (on page 121) for a description of this notation.

The specified standard output of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of POSIX.1-2017, except as provided by this volume of POSIX.1-2017.

Some of the standard utilities describe their output using the verb *display*, defined in XBD Section 3.133 (on page 54). Output described in the STDOUT sections of such utilities may be produced using means other than standard output. When standard output is directed to a terminal, the output described shall be written directly to the terminal. Otherwise, the results are undefined.

Default Behavior: When this section is listed as ``Not used.'', it means that the standard output shall not be written when the utility is used as described by this volume of POSIX.1-2017.

STDERR

The STDERR section describes the standard error output of the utility. Only those messages that are purposely sent by the utility are described.

Use of a terminal for standard error may cause any of the standard utilities that write standard error output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

The format of diagnostic messages for most utilities is unspecified, but the language and cultural conventions of diagnostic and informative messages whose format is unspecified by this volume of POSIX.1-2017 should be affected by the setting of *LC_MESSAGES* and *NLSPATH*.

XSI

The specified standard error output of standard utilities shall not depend on the existence or value of the environment variables defined in this volume of POSIX.1-2017, except as provided by this volume of POSIX.1-2017.

Default Behavior: When this section is listed as ``The standard error shall be used only for diagnostic messages.'', it means that, unless otherwise stated, the diagnostic messages shall be sent to the standard error only when the exit status indicates that an error occurred and the utility is used as described by this volume of POSIX.1-2017.

When this section is listed as ``Not used.'', it means that the standard error shall not be used when the utility is used as described in this volume of POSIX.1-2017.

OUTPUT FILES

The OUTPUT FILES section completely describes the files created or modified by the utility. Temporary or system files that are created for internal usage by this utility or other parts of the implementation (for example, spool, log, and audit files) are not described in this, or any, section. The utilities creating such files and the names of such files are unspecified. If applications are written to use temporary or intermediate files, they should use the *TMPDIR* environment variable, if it is set and represents an accessible directory, to select the location of temporary files.

Implementations shall ensure that temporary files, when used by the standard utilities, are named so that different utilities or multiple instances of the same utility can operate simultaneously without regard to their working directories, or any other process characteristic other than process ID. There are two exceptions to this rule:

1. Resources for temporary files other than the name space (for example, disk space, available directory entries, or number of processes allowed) are not guaranteed.
2. Certain standard utilities generate output files that are intended as input for other utilities (for example, *lex* generates **lex.yy.c**), and these cannot have unique names. These cases are explicitly identified in the descriptions of the respective utilities.

Any temporary file created by the implementation shall be removed by the implementation upon a utility's successful exit, exit because of errors, or before termination by any of the SIGHUP, SIGINT, or SIGTERM signals, unless specified otherwise by the utility description.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ); see XBD Chapter 5 (on page 121) for a description of this notation.

Default Behavior: When this section is listed as ``None.'', it means that no files are created or modified as a consequence of direct action on the part of the utility when the utility is used as described by this volume of POSIX.1-2017. However, the utility may

74515 create or modify system files, such as log files, that are outside the utility's normal
74516 execution environment.

74517 **EXTENDED DESCRIPTION**

74518 The EXTENDED DESCRIPTION section provides a place for describing the actions of
74519 very complicated utilities, such as text editors or language processors, which typically
74520 have elaborate command languages.

74521 **Default Behavior:** When this section is listed as ``None.'', no further description is
74522 necessary.

74523 **EXIT STATUS**

74524 The EXIT STATUS section describes the values the utility shall return to the calling
74525 program, or shell, and the conditions that cause these values to be returned. Usually,
74526 utilities return zero for successful completion and values greater than zero for various
74527 error conditions. If specific numeric values are listed in this section, the system shall
74528 use those values for the errors described. In some cases, status values are listed more
74529 loosely, such as >0. A strictly conforming application shall not rely on any specific
74530 value in the range shown and shall be prepared to receive any value in the range.

74531 For example, a utility may list zero as a successful return, 1 as a failure for a specific
74532 reason, and >1 as ``an error occurred''. In this case, unspecified conditions may cause a
74533 2 or 3, or other value, to be returned. A conforming application should be written so
74534 that it tests for successful exit status values (zero in this case), rather than relying upon
74535 the single specific error value listed in this volume of POSIX.1-2017. In that way, it has
74536 maximum portability, even on implementations with extensions.

74537 Unspecified error conditions may be represented by specific values not listed in this
74538 volume of POSIX.1-2017.

74539 **CONSEQUENCES OF ERRORS**

74540 The CONSEQUENCES OF ERRORS section describes the effects on the environment,
74541 file systems, process state, and so on, when error conditions occur. It does not describe
74542 error messages produced or exit status values used.

74543 The many reasons for failure of a utility are generally not specified by the utility
74544 descriptions. Utilities may terminate prematurely if they encounter: invalid usage of
74545 options, arguments, or environment variables; invalid usage of the complex syntaxes
74546 expressed in EXTENDED DESCRIPTION sections; resource exhaustion; difficulties
74547 accessing, creating, reading, or writing files; or difficulties associated with the
74548 privileges of the process.

74549 The following shall apply to each utility, unless otherwise stated:

74550 If the requested action cannot be performed on an operand representing a file,
74551 directory, user, process, and so on, the utility shall issue a diagnostic message to
74552 standard error and continue processing the next operand in sequence, but the
74553 final exit status shall be returned as non-zero.

74554 For a utility that recursively traverses a file hierarchy (such as *find* or *chown* **–R**), if
74555 the requested action cannot be performed on a file or directory encountered in the
74556 hierarchy, the utility shall issue a diagnostic message to standard error and
74557 continue processing the remaining files in the hierarchy, but the final exit status
74558 shall be returned as non-zero.

74559 If the requested action characterized by an option or option-argument cannot be
74560 performed, the utility shall issue a diagnostic message to standard error and the
74561 exit status returned shall be non-zero.

74562 When an unrecoverable error condition is encountered, the utility shall exit with a
74563 non-zero exit status.

74564 A diagnostic message shall be written to standard error whenever an error
74565 condition occurs.

74566 When a utility encounters an error condition several actions are possible, depending on
74567 the severity of the error and the state of the utility. Included in the possible actions of
74568 various utilities are: deletion of temporary or intermediate work files; deletion of
74569 incomplete files; validity checking of the file system or directory.

74570 **Default Behavior:** When this section is listed as ``Default.'', it means that any changes
74571 to the environment, file systems, process state, and so on are unspecified.

74572 **APPLICATION USAGE**

74573 This section is informative.

74574 The APPLICATION USAGE section gives advice to the application programmer or
74575 user about the way the utility should be used.

74576 **EXAMPLES**

74577 This section is informative.

74578 The EXAMPLES section gives one or more examples of usage, where appropriate. In
74579 the event of conflict between an example and a normative part of the specification, the
74580 normative material is to be taken as correct.

74581 In all examples, quoting has been used, showing how sample commands (utility names
74582 combined with arguments) could be passed correctly to a shell (see *sh*) or as a string to
74583 the *system*( ) function defined in the System Interfaces volume of POSIX.1-2017. Such
74584 quoting would not be used if the utility is invoked using one of the *exec* functions
74585 defined in the System Interfaces volume of POSIX.1-2017.

74586 **RATIONALE**

74587 This section is informative.

74588 This section contains historical information concerning the contents of this volume of
74589 POSIX.1-2017 and why features were included or discarded by the standard
74590 developers.

74591 **FUTURE DIRECTIONS**

74592 This section is informative.

74593 The FUTURE DIRECTIONS section should be used as a guide to current thinking; there
74594 is not necessarily a commitment to implement all of these future directions in their
74595 entirety.

74596 **SEE ALSO**

74597 This section is informative.

74598 The SEE ALSO section lists related entries.

74599 **CHANGE HISTORY**

74600 This section is informative.

74601 This section shows the derivation of the entry and any significant changes that have
74602 been made to it.

74603 Certain of the standard utilities describe how they can invoke other utilities or applications, such
74604 as by passing a command string to the command interpreter. The external influences (STDIN,
74605 ENVIRONMENT VARIABLES, and so on) and external effects (STDOUT, CONSEQUENCES OF

ERRORS, and so on) of such invoked utilities are not described in the section concerning the standard utility that invokes them.

1.5 Considerations for Utilities in Support of Files of Arbitrary Size

The following utilities support files of any size up to the maximum that can be created by the implementation. This support includes correct writing of file size-related values (such as file sizes and offsets, line numbers, and block counts) and correct interpretation of command line arguments that contain such values.

basename	Return non-directory portion of pathname.
cat	Concatenate and print files.
cd	Change working directory.
chgrp	Change file group ownership.
chmod	Change file modes.
chown	Change file ownership.
cksum	Write file checksums and sizes.
cmp	Compare two files.
cp	Copy files.
dd	Convert and copy a file.
df	Report free disk space.
dirname	Return directory portion of pathname.
du	Estimate file space usage.
find	Find files.
ln	Link files.
ls	List directory contents.
mkdir	Make directories.
mv	Move files.
pathchk	Check pathnames.
pwd	Return working directory name.
rm	Remove directory entries.
rmdir	Remove directories.
sh	Shell, the standard command language interpreter.
sum	Print checksum and block or byte count of a file.
test	Evaluate expression.
touch	Change file access and modification times.
ulimit	Set or report file size limit.

Exceptions to the requirement that utilities support files of any size up to the maximum are as follows:

1. Uses of files as command scripts, or for configuration or control, are exempt. For example, it is not required that *sh* be able to read an arbitrarily large **.profile**.
2. Shell input and output redirection are exempt. For example, it is not required that the redirections *sum* < *file* or *echo foo* > *file* succeed for an arbitrarily large existing file.

1.6 Built-In Utilities

Any of the standard utilities may be implemented as regular built-in utilities within the command language interpreter. This is usually done to increase the performance of frequently used utilities or to achieve functionality that would be more difficult in a separate environment. The utilities named in Table 1-5 are frequently provided in built-in form. All of the utilities named in the table have special properties in terms of command search order within the shell, as described in Section 2.9.1.1 (on page 2367).

Table 1-5 Regular Built-In Utilities

alias	*false*	*hash*	*pwd*	*ulimit*
bg	*fc*	*jobs*	*read*	*umask*
cd	*fg*	*kill*	*true*	*unalias*
command	*getopts*	*newgrp*	*type*	*wait*

However, all of the standard utilities, including the regular built-ins in the table, but not the special built-ins described in Section 2.14 (on page 2384), shall be implemented in a manner so that they can be accessed via the *exec* family of functions as defined in the System Interfaces volume of POSIX.1-2017 and can be invoked directly by those standard utilities that require it (*env*, *find*, *nice*, *nohup*, *time*, *xargs*).

74663 Chapter 2

74664 # Shell Command Language

74665 This chapter contains the definition of the Shell Command Language.

74666 ## 2.1 Shell Introduction

74667 The shell is a command language interpreter. This chapter describes the syntax of that command
74668 language as it is used by the *sh* utility and the *system*( ) and *popen*( ) functions defined in the
74669 System Interfaces volume of POSIX.1-2017.

74670 The shell operates according to the following general overview of operations. The specific
74671 details are included in the cited sections of this chapter.

74672 1. The shell reads its input from a file (see *sh*), from the **−c** option or from the *system*( ) and
74673 *popen*( ) functions defined in the System Interfaces volume of POSIX.1-2017. If the first
74674 line of a file of shell commands starts with the characters `"#!"`, the results are
74675 unspecified.

74676 2. The shell breaks the input into tokens: words and operators; see Section 2.3.

74677 3. The shell parses the input into simple commands (see Section 2.9.1) and compound
74678 commands (see Section 2.9.4).

74679 4. The shell performs various expansions (separately) on different parts of each command,
74680 resulting in a list of pathnames and fields to be treated as a command and arguments; see
74681 Section 2.6.

74682 5. The shell performs redirection (see Section 2.7) and removes redirection operators and
74683 their operands from the parameter list.

74684 6. The shell executes a function (see Section 2.9.5), built-in (see Section 2.14), executable file,
74685 or script, giving the names of the arguments as positional parameters numbered 1 to *n*,
74686 and the name of the command (or in the case of a function within a script, the name of the
74687 script) as the positional parameter numbered 0 (see Section 2.9.1.1).

74688 7. The shell optionally waits for the command to complete and collects the exit status (see
74689 Section 2.8.2).

2.2 Quoting

Quoting is used to remove the special meaning of certain characters or words to the shell. Quoting can be used to preserve the literal meaning of the special characters in the next paragraph, prevent reserved words from being recognized as such, and prevent parameter expansion and command substitution within here-document processing (see Section 2.7.4).

The application shall quote the following characters if they are to represent themselves:

```
|  &  ;  <  >  (  )  $  `  \  "  '  <space>  <tab>  <newline>
```

and the following may need to be quoted under certain circumstances. That is, these characters may be special depending on conditions described elsewhere in this volume of POSIX.1-2017:

```
*  ?  [  #  ~  =  %
```

The various quoting mechanisms are the escape character, single-quotes, and double-quotes. The here-document represents another form of quoting; see Section 2.7.4.

2.2.1 Escape Character (Backslash)

A <backslash> that is not quoted shall preserve the literal value of the following character, with the exception of a <newline>. If a <newline> follows the <backslash>, the shell shall interpret this as line continuation. The <backslash> and <newline> shall be removed before splitting the input into tokens. Since the escaped <newline> is removed entirely from the input and is not replaced by any white space, it cannot serve as a token separator.

2.2.2 Single-Quotes

Enclosing characters in single-quotes (`''`) shall preserve the literal value of each character within the single-quotes. A single-quote cannot occur within single-quotes.

2.2.3 Double-Quotes

Enclosing characters in double-quotes (`""`) shall preserve the literal value of all characters within the double-quotes, with the exception of the characters backquote, <dollar-sign>, and <backslash>, as follows:

`$` The <dollar-sign> shall retain its special meaning introducing parameter expansion (see Section 2.6.2), a form of command substitution (see Section 2.6.3), and arithmetic expansion (see Section 2.6.4).

The input characters within the quoted string that are also enclosed between `"$("` and the matching `')'` shall not be affected by the double-quotes, but rather shall define that command whose output replaces the `"$(...)"` when the word is expanded. The tokenizing rules in Section 2.3, not including the alias substitutions in Section 2.3.1, shall be applied recursively to find the matching `')'`.

Within the string of characters from an enclosed `"${"` to the matching `'}'`, an even number of unescaped double-quotes or single-quotes, if any, shall occur. A preceding <backslash> character shall be used to escape a literal `'{'` or `'}'`. The rule in Section 2.6.2 shall be used to determine the matching `'}'`.

74727 ` The backquote shall retain its special meaning introducing the other form of command
74728 substitution (see Section 2.6.3). The portion of the quoted string from the initial backquote
74729 and the characters up to the next backquote that is not preceded by a <backslash>, having
74730 escape characters removed, defines that command whose output replaces "`...`" when
74731 the word is expanded. Either of the following cases produces undefined results:

74732 A single-quoted or double-quoted string that begins, but does not end, within the
74733 "`...`" sequence

74734 A "`...`" sequence that begins, but does not end, within the same double-quoted
74735 string

74736 \ The <backslash> shall retain its special meaning as an escape character (see Section 2.2.1)
74737 only when followed by one of the following characters when considered special:

74738 `$ ` " \ <newline>`

74739 The application shall ensure that a double-quote is preceded by a <backslash> to be included
74740 within double-quotes. The parameter '@' has special meaning inside double-quotes and is
74741 described in Section 2.5.2.

74742 2.3 Token Recognition

74743 The shell shall read its input in terms of lines. (For details about how the shell reads its input, see
74744 the description of *sh*.) The input lines can be of unlimited length. These lines shall be parsed
74745 using two major modes: ordinary token recognition and processing of here-documents.

74746 When an **io_here** token has been recognized by the grammar (see Section 2.10), one or more of
74747 the subsequent lines immediately following the next **NEWLINE** token form the body of one or
74748 more here-documents and shall be parsed according to the rules of Section 2.7.4.

74749 When it is not processing an **io_here**, the shell shall break its input into tokens by applying the
74750 first applicable rule below to the next character in its input. The token shall be from the current
74751 position in the input until a token is delimited according to one of the rules below; the characters
74752 forming the token are exactly those in the input, including any quoting characters. If it is
74753 indicated that a token is delimited, and no characters have been included in a token, processing
74754 shall continue until an actual token is delimited.

74755 1. If the end of input is recognized, the current token (if any) shall be delimited.

74756 2. If the previous character was used as part of an operator and the current character is not
74757 quoted and can be used with the previous characters to form an operator, it shall be used
74758 as part of that (operator) token.

74759 3. If the previous character was used as part of an operator and the current character cannot
74760 be used with the previous characters to form an operator, the operator containing the
74761 previous character shall be delimited.

74762 4. If the current character is <backslash>, single-quote, or double-quote and it is not quoted,
74763 it shall affect quoting for subsequent characters up to the end of the quoted text. The rules
74764 for quoting are as described in Section 2.2. During token recognition no substitutions
74765 shall be actually performed, and the result token shall contain exactly the characters that
74766 appear in the input (except for <newline> joining), unmodified, including any embedded
74767 or enclosing quotes or substitution operators, between the <quotation-mark> and the end
74768 of the quoted text. The token shall not be delimited by the end of the quoted field.

5. If the current character is an unquoted '$' or '`', the shell shall identify the start of any candidates for parameter expansion (Section 2.6.2), command substitution (Section 2.6.3), or arithmetic expansion (Section 2.6.4) from their introductory unquoted character sequences: '$' or "${", "$(" or '`', and "$((", respectively. The shell shall read sufficient input to determine the end of the unit to be expanded (as explained in the cited sections). While processing the characters, if instances of expansions or quoting are found nested within the substitution, the shell shall recursively process them in the manner specified for the construct that is found. The characters found from the beginning of the substitution to its end, allowing for any recursion necessary to recognize embedded constructs, shall be included unmodified in the result token, including any embedded or enclosing substitution operators or quotes. The token shall not be delimited by the end of the substitution.

6. If the current character is not quoted and can be used as the first character of a new operator, the current token (if any) shall be delimited. The current character shall be used as the beginning of the next (operator) token.

7. If the current character is an unquoted <blank>, any token containing the previous character is delimited and the current character shall be discarded.

8. If the previous character was part of a word, the current character shall be appended to that word.

9. If the current character is a '#', it and all subsequent characters up to, but excluding, the next <newline> shall be discarded as a comment. The <newline> that ends the line is not considered part of the comment.

10. The current character is used as the start of a new word.

Once a token is delimited, it is categorized as required by the grammar in Section 2.10.

2.3.1 Alias Substitution

After a token has been delimited, but before applying the grammatical rules in Section 2.10, a resulting word that is identified to be the command name word of a simple command shall be examined to determine whether it is an unquoted, valid alias name. However, reserved words in correct grammatical context shall not be candidates for alias substitution. A valid alias name (see XBD Section 3.10) shall be one that has been defined by the *alias* utility and not subsequently undefined using *unalias*. Implementations also may provide predefined valid aliases that are in effect when the shell is invoked. To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word shall be replaced by the value of the alias; otherwise, it shall not be replaced.

If the value of the alias replacing the word ends in a <blank>, the shell shall check the next command word for alias substitution; this process shall continue until a word is found that is not a valid alias or an alias value does not end in a <blank>.

When used as specified by this volume of POSIX.1-2017, alias definitions shall not be inherited by separate invocations of the shell or by the utility execution environments invoked by the shell; see Section 2.12.

2.4 Reserved Words

Reserved words are words that have special meaning to the shell; see Section 2.9. The following words shall be recognized as reserved words:

!	**do**	**esac**	**in**
{	**done**	**fi**	**then**
}	**elif**	**for**	**until**
case	**else**	**if**	**while**

This recognition shall only occur when none of the characters is quoted and when the word is used as:

The first word of a command

The first word following one of the reserved words other than **case**, **for**, or **in**

The third word in a **case** command (only **in** is valid in this case)

The third word in a **for** command (only **in** and **do** are valid in this case)

See the grammar in Section 2.10.

The following words may be recognized as reserved words on some implementations (when none of the characters are quoted), causing unspecified results:

[[	**]]**	**function**	**select**

Words that are the concatenation of a name and a <colon> (`':'`) are reserved; their use produces unspecified results.

2.5 Parameters and Variables

A parameter can be denoted by a name, a number, or one of the special characters listed in Section 2.5.2. A variable is a parameter denoted by a name.

A parameter is set if it has an assigned value (null is a valid value). Once a variable is set, it can only be unset by using the *unset* special built-in command.

2.5.1 Positional Parameters

A positional parameter is a parameter denoted by the decimal value represented by one or more digits, other than the single digit 0. The digits denoting the positional parameters shall always be interpreted as a decimal value, even if there is a leading zero. When a positional parameter with more than one digit is specified, the application shall enclose the digits in braces (see Section 2.6.2). Positional parameters are initially assigned when the shell is invoked (see *sh*), temporarily replaced when a shell function is invoked (see Section 2.9.5), and can be reassigned with the *set* special built-in command.

2.5.2 Special Parameters

Listed below are the special parameters and the values to which they shall expand. Only the values of the special parameters are listed; see Section 2.6 for a detailed summary of all the stages involved in expanding words.

`@` Expands to the positional parameters, starting from one, initially producing one field for each positional parameter that is set. When the expansion occurs in a context where field splitting will be performed, any empty fields may be discarded and each of the non-empty fields shall be further split as described in Section 2.6.5. When the expansion occurs within double-quotes, the behavior is unspecified unless one of the following is true:

> Field splitting as described in Section 2.6.5 would be performed if the expansion were not within double-quotes (regardless of whether field splitting would have any effect; for example, if *IFS* is null).
>
> The double-quotes are within the *word* of a ${*parameter*:–*word*} or a ${*parameter*:+*word*} expansion (with or without the <colon>; see Section 2.6.2) which would have been subject to field splitting if *parameter* had been expanded instead of *word*.

If one of these conditions is true, the initial fields shall be retained as separate fields, except that if the parameter being expanded was embedded within a word, the first field shall be joined with the beginning part of the original word and the last field shall be joined with the end part of the original word. In all other contexts the results of the expansion are unspecified. If there are no positional parameters, the expansion of `'@'` shall generate zero fields, even when `'@'` is within double-quotes; however, if the expansion is embedded within a word which contains one or more other parts that expand to a quoted null string, these null string(s) shall still produce an empty field, except that if the other parts are all within the same double-quotes as the `'@'`, it is unspecified whether the result is zero fields or one empty field.

`*` Expands to the positional parameters, starting from one, initially producing one field for each positional parameter that is set. When the expansion occurs in a context where field splitting will be performed, any empty fields may be discarded and each of the non-empty fields shall be further split as described in Section 2.6.5. When the expansion occurs in a context where field splitting will not be performed, the initial fields shall be joined to form a single field with the value of each parameter separated by the first character of the *IFS* variable if *IFS* contains at least one character, or separated by a <space> if *IFS* is unset, or with no separation if *IFS* is set to a null string.

`#` Expands to the decimal number of positional parameters. The command name (parameter 0) shall not be counted in the number given by `'#'` because it is a special parameter, not a positional parameter.

`?` Expands to the decimal exit status of the most recent pipeline (see Section 2.9.2).

`–` (Hyphen.) Expands to the current option flags (the single-letter option names concatenated into a string) as specified on invocation, by the *set* special built-in command, or implicitly by the shell.

`$` Expands to the decimal process ID of the invoked shell. In a subshell (see Section 2.12), `'$'` shall expand to the same value as that of the current shell.

`!` Expands to the decimal process ID of the most recent background command (see Section 2.9.3) executed from the current shell. (For example, background commands executed from subshells do not affect the value of `"$!"` in the current shell environment.) For a pipeline, the process ID is that of the last command in the pipeline.

74887 0 (Zero.) Expands to the name of the shell or shell script. See *sh* for a detailed description of
74888 how this name is derived.

74889 See the description of the *IFS* variable in Section 2.5.3.

74890 2.5.3 Shell Variables

74891 Variables shall be initialized from the environment (as defined by XBD Chapter 8 and the *exec*
74892 function in the System Interfaces volume of POSIX.1-2017) and can be given new values with
74893 variable assignment commands. If a variable is initialized from the environment, it shall be
74894 marked for export immediately; see the *export* special built-in. New variables can be defined and
74895 initialized with variable assignments, with the *read* or *getopts* utilities, with the *name* parameter
74896 in a **for** loop, with the ${*name*=*word*} expansion, or with other mechanisms provided as
74897 implementation extensions.

74898 The following variables shall affect the execution of the shell:

74899 UP *ENV* The processing of the *ENV* shell variable shall be supported if the system
74900 supports the User Portability Utilities option.

74901 This variable, when and only when an interactive shell is invoked, shall be
74902 subjected to parameter expansion (see Section 2.6.2) by the shell and the
74903 resulting value shall be used as a pathname of a file containing shell
74904 commands to execute in the current environment. The file need not be
74905 executable. If the expanded value of *ENV* is not an absolute pathname, the
74906 results are unspecified. *ENV* shall be ignored if the user's real and effective
74907 user IDs or real and effective group IDs are different.

74908 *HOME* The pathname of the user's home directory. The contents of *HOME* are used in
74909 tilde expansion (see Section 2.6.1).

74910 *IFS* A string treated as a list of characters that is used for field splitting, expansion
74911 of the `'*'` special parameter, and to split lines into fields with the *read* utility.
74912 If the value of *IFS* includes any bytes that do not form part of a valid character,
74913 the results of field splitting, expansion of `'*'`, and use of the *read* utility are
74914 unspecified.

74915 If *IFS* is not set, it shall behave as normal for an unset variable, except that
74916 field splitting by the shell and line splitting by the *read* utility shall be
74917 performed as if the value of *IFS* is <space><tab><newline>; see Section 2.6.5.

74918 The shell shall set *IFS* to <space><tab><newline> when it is invoked.

74919 *LANG* Provide a default value for the internationalization variables that are unset or
74920 null. (See XBD Section 8.2 for the precedence of internationalization variables
74921 used to determine the values of locale categories.)

74922 *LC_ALL* The value of this variable overrides the *LC_** variables and *LANG*, as
74923 described in XBD Chapter 8.

74924 *LC_COLLATE* Determine the behavior of range expressions, equivalence classes, and multi-
74925 character collating elements within pattern matching.

74926 *LC_CTYPE* Determine the interpretation of sequences of bytes of text data as characters
74927 (for example, single-byte as opposed to multi-byte characters), which
74928 characters are defined as letters (character class **alpha**) and <blank> characters
74929 (character class **blank**), and the behavior of character classes within pattern
74930 matching. Changing the value of *LC_CTYPE* after the shell has started shall

not affect the lexical processing of shell commands in the current shell execution environment or its subshells. Invoking a shell script or performing *exec sh* subjects the new shell to the changes in *LC_CTYPE*.

LC_MESSAGES Determine the language in which messages should be written.

LINENO Set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets *LINENO*, the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of *LINENO* is unspecified. This volume of POSIX.1-2017 specifies the effects of the variable only for systems supporting the User Portability Utilities option.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH A string formatted as described in XBD Chapter 8, used to effect command interpretation; see Section 2.9.1.1.

PPID Set by the shell to the decimal value of its parent process ID during initialization of the shell. In a subshell (see Section 2.12), *PPID* shall be set to the same value as that of the parent of the current shell. For example, *echo* $*PPID* and (*echo* $*PPID*) would produce the same value.

PS1 Each time an interactive shell is ready to read a command, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value shall be `"$ "`. For users who have specific additional implementation-defined privileges, the default may be another, implementation-defined value. The shell shall replace each instance of the character `'!'` in *PS1* with the history file number of the next command to be typed. Escaping the `'!'` with another `'!'` (that is, `"!!"`) shall place the literal character `'!'` in the prompt. This volume of POSIX.1-2017 specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PS2 Each time the user enters a <newline> prior to completing a command line in an interactive shell, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is `"> "`. This volume of POSIX.1-2017 specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PS4 When an execution trace (*set* **–x**) is being performed in an interactive shell, before each line in the execution trace, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is `"+ "`. This volume of POSIX.1-2017 specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PWD Set by the shell and by the *cd* utility. In the shell the value shall be initialized from the environment as follows. If a value for *PWD* is passed to the shell in the environment when it is executed, the value is an absolute pathname of the current working directory that is no longer than {PATH_MAX} bytes including the terminating null byte, and the value does not contain any components that are dot or dot-dot, then the shell shall set *PWD* to the value from the environment. Otherwise, if a value for *PWD* is passed to the shell in the environment when it is executed, the value is an absolute pathname of the current working directory, and the value does not contain any components

that are dot or dot-dot, then it is unspecified whether the shell sets *PWD* to the value from the environment or sets *PWD* to the pathname that would be output by *pwd* **–P**. Otherwise, the *sh* utility sets *PWD* to the pathname that would be output by *pwd* **–P**. In cases where *PWD* is set to the value from the environment, the value can contain components that refer to files of type symbolic link. In cases where *PWD* is set to the pathname that would be output by *pwd* **–P**, if there is insufficient permission on the current working directory, or on any parent of that directory, to determine what that pathname would be, the value of *PWD* is unspecified. Assignments to this variable may be ignored. If an application sets or unsets the value of *PWD*, the behaviors of the *cd* and *pwd* utilities are unspecified.

2.6 Word Expansions

This section describes the various expansions that are performed on words. Not all expansions are performed on every word, as explained in the following sections.

Tilde expansions, parameter expansions, command substitutions, arithmetic expansions, and quote removals that occur within a single word expand to a single field. It is only field splitting or pathname expansion that can create multiple fields from a single word. The single exception to this rule is the expansion of the special parameter `'@'` within double-quotes, as described in Section 2.5.2.

The order of word expansion shall be as follows:

1. Tilde expansion (see Section 2.6.1), parameter expansion (see Section 2.6.2), command substitution (see Section 2.6.3), and arithmetic expansion (see Section 2.6.4) shall be performed, beginning to end. See item 5 in Section 2.3.
2. Field splitting (see Section 2.6.5) shall be performed on the portions of the fields generated by step 1, unless *IFS* is null.
3. Pathname expansion (see Section 2.6.6) shall be performed, unless *set* **–f** is in effect.
4. Quote removal (see Section 2.6.7) shall always be performed last.

The expansions described in this section shall occur in the same shell environment as that in which the command is executed.

If the complete expansion appropriate for a word results in an empty field, that empty field shall be deleted from the list of fields that form the completely expanded command, unless the original word contained single-quote or double-quote characters.

The `'$'` character is used to introduce parameter expansion, command substitution, or arithmetic evaluation. If an unquoted `'$'` is followed by a character that is not one of the following:

A numeric character

The name of one of the special parameters (see Section 2.5.2)

A valid first character of a variable name

A <left-curly-bracket> (`'{'`)

A <left-parenthesis>

the result is unspecified.

2.6.1 Tilde Expansion

A ``tilde-prefix'' consists of an unquoted <tilde> character at the beginning of a word, followed by all of the characters preceding the first unquoted <slash> in the word, or all the characters in the word if there is no <slash>. In an assignment (see XBD Section 4.23), multiple tilde-prefixes can be used: at the beginning of the word (that is, following the <equals-sign> of the assignment), following any unquoted <colon>, or both. A tilde-prefix in an assignment is terminated by the first unquoted <colon> or <slash>. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the <tilde> are treated as a possible login name from the user database. A portable login name cannot contain characters outside the set given in the description of the *LOGNAME* environment variable in XBD Section 8.3. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix is replaced by the value of the variable *HOME*. If *HOME* is unset, the results are unspecified. Otherwise, the tilde-prefix shall be replaced by a pathname of the initial working directory associated with the login name obtained using the *getpwnam*() function as defined in the System Interfaces volume of POSIX.1-2017. If the system does not recognize the login name, the results are undefined.

The pathname resulting from tilde expansion shall be treated as if quoted to prevent it being altered by field splitting and pathname expansion.

2.6.2 Parameter Expansion

The format for parameter expansion is as follows:

`${`*`expression`*`}`

where *expression* consists of all characters until the matching `'}'`. Any `'}'` escaped by a <backslash> or within a quoted string, and characters in embedded arithmetic expansions, command substitutions, and variable expansions, shall not be examined in determining the matching `'}'`.

The simplest form for parameter expansion is:

`${`*`parameter`*`}`

The value, if any, of *parameter* shall be substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when *parameter* is a name and is followed by a character that could be interpreted as part of the name. The matching closing brace shall be determined by counting brace levels, skipping over enclosed quoted strings, and command substitutions.

If the parameter is not enclosed in braces, and is a name, the expansion shall use the longest valid name (see XBD Section 3.235), whether or not the variable represented by that name exists. Otherwise, the parameter is a single-character symbol, and behavior is unspecified if that character is neither a digit nor one of the special parameters (see Section 2.5.2).

If a parameter expansion occurs inside double-quotes:

- Pathname expansion shall not be performed on the results of the expansion.
- Field splitting shall not be performed on the results of the expansion.

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*, as described below), *word* shall be subjected to tilde expansion, parameter expansion, command substitution, and arithmetic expansion. If *word* is not needed, it shall not be expanded. The `'}'` character that

delimits the following parameter expansion modifications shall be determined as described previously in this section and in Section 2.2.3.

${*parameter*:–[*word*]} **Use Default Values**. If *parameter* is unset or null, the expansion of *word* (or an empty string if *word* is omitted) shall be substituted; otherwise, the value of *parameter* shall be substituted.

${*parameter*:=[*word*]} **Assign Default Values**. If *parameter* is unset or null, the expansion of *word* (or an empty string if *word* is omitted) shall be assigned to *parameter*. In all cases, the final value of *parameter* shall be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.

${*parameter*:?[*word*]} **Indicate Error if Null or Unset**. If *parameter* is unset or null, the expansion of *word* (or a message indicating it is unset if *word* is omitted) shall be written to standard error and the shell exits with a non-zero exit status. Otherwise, the value of *parameter* shall be substituted. An interactive shell need not exit.

${*parameter*:+[*word*]} **Use Alternative Value**. If *parameter* is unset or null, null shall be substituted; otherwise, the expansion of *word* (or an empty string if *word* is omitted) shall be substituted.

In the parameter expansions shown previously, use of the <colon> in the format shall result in a test for a parameter that is unset or null; omission of the <colon> shall result in a test for a parameter that is only unset. If parameter is `'#'` and the colon is omitted, the application shall ensure that *word* is specified (this is necessary to avoid ambiguity with the string length expansion). The following table summarizes the effect of the <colon>:

	parameter **Set and Not Null**	*parameter* **Set But Null**	*parameter* **Unset**
${*parameter***:–***word***}**	substitute *parameter*	substitute *word*	substitute *word*
${*parameter***–***word***}**	substitute *parameter*	substitute null	substitute *word*
${*parameter***:=***word***}**	substitute *parameter*	assign *word*	assign *word*
${*parameter***=***word***}**	substitute *parameter*	substitute null	assign *word*
${*parameter***:?***word***}**	substitute *parameter*	error, exit	error, exit
${*parameter***?***word***}**	substitute *parameter*	substitute null	error, exit
${*parameter***:+***word***}**	substitute *word*	substitute null	substitute null
${*parameter***+***word***}**	substitute *word*	substitute *word*	substitute null

In all cases shown with ``substitute'', the expression is replaced with the value shown. In all cases shown with ``assign'', *parameter* is assigned that value, which also replaces the expression.

${#*parameter*} **String Length**. The length in characters of the value of *parameter* shall be substituted. If *parameter* is `'*'` or `'@'`, the result of the expansion is unspecified. If *parameter* is unset and *set* –**u** is in effect, the expansion shall fail.

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see Section 2.13), rather than regular expression notation, shall be used to evaluate the patterns. If *parameter* is `'#'`, `'*'`, or `'@'`, the result of the expansion is unspecified. If *parameter* is unset and *set* –**u** is in effect, the expansion shall fail. Enclosing the full parameter expansion string in double-quotes shall not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces shall have this effect. In each variety, if *word* is omitted, the empty pattern shall be used.

75109 ${*parameter*%[*word*]} **Remove Smallest Suffix Pattern**. The *word* shall be expanded to produce
75110 a pattern. The parameter expansion shall then result in *parameter*, with the
75111 smallest portion of the suffix matched by the *pattern* deleted. If present,
75112 *word* shall not begin with an unquoted `'%'`.

75113 ${*parameter*%%[*word*]} **Remove Largest Suffix Pattern**. The *word* shall be expanded to produce a
75114 pattern. The parameter expansion shall then result in *parameter*, with the
75115 largest portion of the suffix matched by the *pattern* deleted.

75116 ${*parameter*#[*word*]} **Remove Smallest Prefix Pattern**. The *word* shall be expanded to produce
75117 a pattern. The parameter expansion shall then result in *parameter*, with the
75118 smallest portion of the prefix matched by the *pattern* deleted. If present,
75119 *word* shall not begin with an unquoted `'#'`.

75120 ${*parameter*##[*word*]} **Remove Largest Prefix Pattern**. The *word* shall be expanded to produce a
75121 pattern. The parameter expansion shall then result in *parameter*, with the
75122 largest portion of the prefix matched by the *pattern* deleted.

75123 **Examples**

75124 ${*parameter*}
75125 In this example, the effects of omitting braces are demonstrated.

```
75126 a=1
75127 set 2
75128 echo ${a}b-$ab-${1}0-${10}-$10
75129 1b--20--20
```

75130 ${*parameter*–*word*}
75131 This example demonstrates the difference between unset and set to the empty string, as well
75132 as the rules for finding the delimiting close brace.

```
75133     foo=asdf
75134     echo ${foo-bar}xyz}
75135     asdfxyz}
75136     foo=
75137     echo ${foo-bar}xyz}
75138     xyz}
75139     unset foo
75140     echo ${foo-bar}xyz}
75141     barxyz}
```

75142 ${*parameter*:–*word*}
75143 In this example, *ls* is executed only if *x* is null or unset. (The $(*ls*) command substitution
75144 notation is explained in Section 2.6.3.)

```
75145 ${x:-$(ls)}
```

75146 ${*parameter*:=*word*}

```
75147 unset X
75148 echo ${X:=abc}
75149 abc
```

75150 ${*parameter*:?*word*}

```
75151 unset posix
75152 echo ${posix:?}
75153 sh: posix: parameter null or not set
```

75154 ${*parameter*:+*word*}

```
set a b c
echo ${3:+posix}
```

posix

75158 ${#*parameter*}

```
HOME=/usr/posix
echo ${#HOME}
```

10

75162 ${*parameter*%*word*}

```
x=file.c
echo ${x%.c}.o
```

file.o

75166 ${*parameter*%%*word*}

```
x=posix/src/std
echo ${x%%/*}
```

posix

75170 ${*parameter*#*word*}

```
x=$HOME/src/cmd
echo ${x#$HOME}
```

/src/cmd

75174 ${*parameter*##*word*}

```
x=/one/two/three
echo ${x##*/}
```

three

75178 The double-quoting of patterns is different depending on where the double-quotes are placed:

75179 `"${x#*}"` The <asterisk> is a pattern character.

75180 `${x#"*"}` The literal <asterisk> is quoted and not special.

75181 2.6.3 Command Substitution

75182 Command substitution allows the output of a command to be substituted in place of the
75183 command name itself. Command substitution shall occur when the command is enclosed as
75184 follows:

75185 `$(`*command*`)`

75186 or (backquoted version):

75187 `` `command` ``

75188 The shell shall expand the command substitution by executing *command* in a subshell
75189 environment (see Section 2.12) and replacing the command substitution (the text of *command*
75190 plus the enclosing `"$()"` or backquotes) with the standard output of the command, removing
75191 sequences of one or more <newline> characters at the end of the substitution. Embedded
75192 <newline> characters before the end of the output shall not be removed; however, they may be
75193 treated as field delimiters and eliminated during field splitting, depending on the value of *IFS*
75194 and quoting that is in effect. If the output contains any null bytes, the behavior is unspecified.

75195 Within the backquoted style of command substitution, <backslash> shall retain its literal
75196 meaning, except when followed by: `'$'`, `'`'`, or <backslash>. The search for the matching

backquote shall be satisfied by the first unquoted non-escaped backquote; during this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the $(*command*) form, or a quoted string, undefined results occur. A single-quoted or double-quoted string that begins, but does not end, within the "`...`" sequence produces undefined results.

With the $(*command*) form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except a script consisting solely of redirections which produces unspecified results.

The results of command substitution shall not be processed for further tilde expansion, parameter expansion, command substitution, or arithmetic expansion. If a command substitution occurs inside double-quotes, field splitting and pathname expansion shall not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application shall precede the inner backquotes with <backslash> characters; for example:

```
\`command\`
```

The syntax of the shell command language has an ambiguity for expansions beginning with "$((", which can introduce an arithmetic expansion or a command substitution that starts with a subshell. Arithmetic expansion has precedence; that is, the shell shall first determine whether it can parse the expansion as an arithmetic expansion and shall only parse the expansion as a command substitution if it determines that it cannot parse the expansion as an arithmetic expansion. The shell need not evaluate nested expansions when performing this determination. If it encounters the end of input without already having determined that it cannot parse the expansion as an arithmetic expansion, the shell shall treat the expansion as an incomplete arithmetic expansion and report a syntax error. A conforming application shall ensure that it separates the "$(" and '(' into two tokens (that is, separate them with white space) in a command substitution that starts with a subshell. For example, a command substitution containing a single subshell could be written as:

```
$( (command) )
```

2.6.4 Arithmetic Expansion

Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion shall be as follows:

```
$((expression))
```

The expression shall be treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell shall expand all tokens in the expression for parameter expansion, command substitution, and quote removal.

Next, the shell shall treat this as an arithmetic expression and substitute the value of the expression. The arithmetic expression shall be processed according to the rules given in Section 1.1.2.1, with the following exceptions:

- Only signed long integer arithmetic is required.
- Only the decimal-constant, octal-constant, and hexadecimal-constant constants specified in the ISO C standard, Section 6.4.4.1 are required to be recognized as constants.
- The *sizeof*() operator and the prefix and postfix "++" and "--" operators are not required.

Selection, iteration, and jump statements are not supported.

All changes to variables in an arithmetic expression shall be in effect after the arithmetic expansion, as in the parameter expansion "`${x=value}`".

If the shell variable *x* contains a value that forms a valid integer constant, optionally including a leading <plus-sign> or <hyphen-minus>, then the arithmetic expansions "`$((x))`" and "`$(($x))`" shall return the same value.

As an extension, the shell may recognize arithmetic expressions beyond those listed. The shell may use a signed integer type with a rank larger than the rank of **signed long**. The shell may use a real-floating type instead of **signed long** as long as it does not affect the results in cases where there is no overflow. If the expression is invalid, or the contents of a shell variable used in the expression are not recognized by the shell, the expansion fails and the shell shall write a diagnostic message to standard error indicating the failure.

Examples

A simple example using arithmetic expansion:

```
# repeat a command 100 times
x=100
while [ $x -gt 0 ]
do
    command
    x=$(($x-1))
done
```

2.6.5 Field Splitting

After parameter expansion (Section 2.6.2), command substitution (Section 2.6.3), and arithmetic expansion (Section 2.6.4), the shell shall scan the results of expansions and substitutions that did not occur in double-quotes for field splitting and multiple fields can result.

The shell shall treat each character of the *IFS* as a delimiter and use the delimiters as field terminators to split the results of parameter expansion, command substitution, and arithmetic expansion into fields.

1. If the value of *IFS* is a <space>, <tab>, and <newline>, or if it is unset, any sequence of <space>, <tab>, or <newline> characters at the beginning or end of the input shall be ignored and any sequence of those characters within the input shall delimit a field. For example, the input:

   `<newline><space><tab>foo<tab><tab>bar<space>`

   yields two fields, **foo** and **bar**.

2. If the value of *IFS* is null, no field splitting shall be performed.

3. Otherwise, the following rules shall be applied in sequence. The term ``*IFS* white space'' is used to mean any sequence (zero or more instances) of white-space characters that are in the *IFS* value (for example, if *IFS* contains <space>/<comma>/<tab>, any sequence of <space> and <tab> characters is considered *IFS* white space).

a. *IFS* white space shall be ignored at the beginning and end of the input.

b. Each occurrence in the input of an *IFS* character that is not *IFS* white space, along with any adjacent *IFS* white space, shall delimit a field, as described previously.

c. Non-zero-length *IFS* white space shall delimit a field.

2.6.6 Pathname Expansion

After field splitting, if *set* **−f** is not in effect, each field in the resulting command line shall be expanded using the algorithm described in Section 2.13, qualified by the rules in Section 2.13.3.

2.6.7 Quote Removal

The quote characters (<backslash>, single-quote, and double-quote) that were present in the original word shall be removed unless they have themselves been quoted.

2.7 Redirection

Redirection is used to open and close files for the current shell execution environment (see Section 2.12) or for any command. Redirection operators can be used with numbers representing file descriptors (see XBD Section 3.166) as described below.

The overall format used for redirection is:

```
[n]redir-op word
```

The number *n* is an optional decimal number designating the file descriptor number; the application shall ensure it is delimited from any preceding text and immediately precede the redirection operator *redir-op*. If *n* is quoted, the number shall not be recognized as part of the redirection expression. For example:

```
echo \2>a
```

writes the character 2 into file **a**. If any part of *redir-op* is quoted, no redirection expression is recognized. For example:

```
echo 2\>a
```

writes the characters 2>*a* to standard output. The optional number, redirection operator, and *word* shall not appear in the arguments provided to the command to be executed (if any).

Open files are represented by decimal numbers starting with zero. The largest possible value is implementation-defined; however, all implementations shall support at least 0 to 9, inclusive, for use by the application. These numbers are called ``file descriptors''. The values 0, 1, and 2 have special meaning and conventional uses and are implied by certain redirection operations; they are referred to as *standard input*, *standard output*, and *standard error*, respectively. Programs usually take their input from standard input, and write output on standard output. Error messages are usually written on standard error. The redirection operators can be preceded by one or more digits (with no intervening <blank> characters allowed) to designate the file descriptor number.

If the redirection operator is `"<<"` or `"<<−"`, the word that follows the redirection operator shall be subjected to quote removal; it is unspecified whether any of the other expansions occur. For the other redirection operators, the word that follows the redirection operator shall be subjected

to tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal. Pathname expansion shall not be performed on the word by a non-interactive shell; an interactive shell may perform it, but shall do so only when the expansion would result in one word.

If more than one redirection operator is specified with a command, the order of evaluation is from beginning to end.

A failure to open or create a file shall cause a redirection to fail.

2.7.1 Redirecting Input

Input redirection shall cause the file whose name results from the expansion of *word* to be opened for reading on the designated file descriptor, or standard input if the file descriptor is not specified.

The general format for redirecting input is:

`[`*n*`]<`*word*

where the optional *n* represents the file descriptor number. If the number is omitted, the redirection shall refer to standard input (file descriptor 0).

2.7.2 Redirecting Output

The two general formats for redirecting output are:

`[`*n*`]>`*word*
`[`*n*`]>|`*word*

where the optional *n* represents the file descriptor number. If the number is omitted, the redirection shall refer to standard output (file descriptor 1).

Output redirection using the `'>'` format shall fail if the *noclobber* option is set (see the description of *set* **−C**) and the file named by the expansion of *word* exists and is a regular file. Otherwise, redirection using the `'>'` or `">|"` formats shall cause the file whose name results from the expansion of *word* to be created and opened for output on the designated file descriptor, or standard output if none is specified. If the file does not exist, it shall be created; otherwise, it shall be truncated to be an empty file after being opened.

2.7.3 Appending Redirected Output

Appended output redirection shall cause the file whose name results from the expansion of word to be opened for output on the designated file descriptor. The file is opened as if the *open*( ) function as defined in the System Interfaces volume of POSIX.1-2017 was called with the O_APPEND flag. If the file does not exist, it shall be created.

The general format for appending redirected output is as follows:

`[`*n*`]>>`*word*

where the optional *n* represents the file descriptor number. If the number is omitted, the redirection refers to standard output (file descriptor 1).

2.7.4 Here-Document

The redirection operators "<<" and "<<−" both allow redirection of subsequent lines read by the shell to the input of a command. The redirected lines are known as a ``here-document''.

The here-document shall be treated as a single word that begins after the next <newline> and continues until there is a line containing only the delimiter and a <newline>, with no <blank> characters in between. Then the next here-document starts, if there is one. The format is as follows:

```
[n]<<word
    here-document
delimiter
```

where the optional *n* represents the file descriptor number. If the number is omitted, the here-document refers to standard input (file descriptor 0). It is unspecified whether the file descriptor is opened as a regular file, a special file, or a pipe. Portable applications cannot rely on the file descriptor being seekable (see XSH *lseek*( )).

If any part of *word* is quoted, the delimiter shall be formed by performing quote removal on *word*, and the here-document lines shall not be expanded. Otherwise, the delimiter shall be the *word* itself.

If no part of *word* is quoted, all lines of the here-document shall be expanded for parameter expansion, command substitution, and arithmetic expansion. In this case, the <backslash> in the input behaves as the <backslash> inside double-quotes (see Section 2.2.3). However, the double-quote character ('"') shall not be treated specially within a here-document, except when the double-quote appears within "$()", "``", or "${}".

If the redirection operator is "<<−", all leading <tab> characters shall be stripped from input lines and the line containing the trailing delimiter. If more than one "<<" or "<<−" operator is specified on a line, the here-document associated with the first operator shall be supplied first by the application and shall be read first by the shell.

When a here-document is read from a terminal device and the shell is interactive, it shall write the contents of the variable *PS2*, processed as described in Section 2.5.3, to standard error before reading each line of input until the delimiter has been recognized.

Examples

An example of a here-document follows:

```
cat <<eof1; cat <<eof2
Hi,
eof1
Helene.
eof2
```

2.7.5 Duplicating an Input File Descriptor

The redirection operator:

`[`*n*`]<&`*word*

shall duplicate one input file descriptor from another, or shall close one. If *word* evaluates to one or more digits, the file descriptor denoted by *n*, or standard input if *n* is not specified, shall be made to be a copy of the file descriptor denoted by *word*; if the digits in *word* do not represent a file descriptor already open for input, a redirection error shall result; see Section 2.8.1. If *word* evaluates to `'-'`, file descriptor *n*, or standard input if *n* is not specified, shall be closed. Attempts to close a file descriptor that is not open shall not constitute an error. If *word* evaluates to something else, the behavior is unspecified.

2.7.6 Duplicating an Output File Descriptor

The redirection operator:

`[`*n*`]>&`*word*

shall duplicate one output file descriptor from another, or shall close one. If *word* evaluates to one or more digits, the file descriptor denoted by *n*, or standard output if *n* is not specified, shall be made to be a copy of the file descriptor denoted by *word*; if the digits in *word* do not represent a file descriptor already open for output, a redirection error shall result; see Section 2.8.1. If *word* evaluates to `'-'`, file descriptor *n*, or standard output if *n* is not specified, is closed. Attempts to close a file descriptor that is not open shall not constitute an error. If *word* evaluates to something else, the behavior is unspecified.

2.7.7 Open File Descriptors for Reading and Writing

The redirection operator:

`[`*n*`]<>`*word*

shall cause the file whose name is the expansion of *word* to be opened for both reading and writing on the file descriptor denoted by *n*, or standard input if *n* is not specified. If the file does not exist, it shall be created.

2.8 Exit Status and Errors

2.8.1 Consequences of Shell Errors

Certain errors shall cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

Error	Non-Interactive Shell	Interactive Shell	Shell Diagnostic Message Required
Shell language syntax error	shall exit	shall not exit	yes
Special built-in utility error	shall exit	shall not exit	no[1]
Other utility (not a special built-in) error	shall not exit	shall not exit	no[2]
Redirection error with special built-in utilities	shall exit	shall not exit	yes
Redirection error with compound commands	may exit[3]	shall not exit	yes
Redirection error with function execution	may exit[3]	shall not exit	yes
Redirection error with other utilities (not special built-ins)	shall not exit	shall not exit	yes
Variable assignment error	shall exit	shall not exit	yes
Expansion error	shall exit	shall not exit	yes
Command not found	may exit	shall not exit	yes

Notes:

1. Although special built-ins are part of the shell, a diagnostic message written by a special built-in is not considered to be a shell diagnostic message, and can be redirected like any other utility.
2. The shell is not required to write a diagnostic message, but the utility itself shall write a diagnostic message if required to do so.
3. A future version of this standard may require the shell to not exit in this condition.

An expansion error is one that occurs when the shell expansions define in Section 2.6 are carried out (for example, `"${x!y}"`, because `'!'` is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as ``shall exit'' or ``may exit'' occur in a subshell environment, the shell shall (respectively, may) exit from the subshell environment with a non-zero status and continue in the environment from which that subshell environment was invoked.

In all of the cases shown in the table where an interactive shell is required not to exit, the shell shall not perform any further processing of the command in which the error occurred.

2.8.2 Exit Status for Commands

Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status shall be 127. If the command name is found, but it is not an executable utility, the exit status shall be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status shall be between 1 and 125 inclusive.

Internally, for purposes of deciding whether a command exits with a non-zero exit status, the

shell shall recognize the entire status value retrieved for the command by the equivalent of the *wait*() function WEXITSTATUS macro (as defined in the System Interfaces volume of POSIX.1-2017). When reporting the exit status with the special parameter '?', the shell shall report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal shall be reported as greater than 128.

2.9 Shell Commands

This section describes the basic structure of shell commands. The following command descriptions each describe a format of the command that is only used to aid the reader in recognizing the command type, and does not formally represent the syntax. In particular, the representations include spacing between tokens in some places where <blank>s would not be necessary (when one of the tokens is an operator). Each description discusses the semantics of the command; for a formal definition of the command language, consult Section 2.10.

A *command* is one of the following:

- Simple command (see Section 2.9.1)
- Pipeline (see Section 2.9.2)
- List compound-list (see Section 2.9.3)
- Compound command (see Section 2.9.4)
- Function definition (see Section 2.9.5)

Unless otherwise stated, the exit status of a command shall be that of the last simple command executed by the command. There shall be no limit on the size of any shell command other than that imposed by the underlying system (memory constraints, {ARG_MAX}, and so on).

2.9.1 Simple Commands

A ``simple command'' is a sequence of optional variable assignments and redirections, in any sequence, optionally followed by words and redirections, terminated by a control operator.

When a given simple command is required to be executed (that is, when any conditional construct such as an AND-OR list or a **case** statement has not bypassed the simple command), the following expansions, assignments, and redirections shall all be performed from the beginning of the command text to the end:

1. The words that are recognized as variable assignments or redirections according to Section 2.10.2 are saved for processing in steps 3 and 4.
2. The words that are not variable assignments or redirections shall be expanded. If any fields remain following their expansion, the first field shall be considered the command name and remaining fields are the arguments for the command.
3. Redirections shall be performed as described in Section 2.7.
4. Each variable assignment shall be expanded for tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal prior to assigning the value.

In the preceding list, the order of steps 3 and 4 may be reversed if no command name results from step 2 or if the command name matches the name of a special built-in utility; see Section 2.14.

Variable assignments shall be performed as follows:

If no command name results, variable assignments shall affect the current execution environment.

If the command name is not a special built-in utility or function, the variable assignments shall be exported for the execution environment of the command and shall not affect the current execution environment except as a side-effect of the expansions performed in step 4. In this case it is unspecified:

- ‡ Whether or not the assignments are visible for subsequent expansions in step 4
- ‡ Whether variable assignments made as side-effects of these expansions are visible for subsequent expansions in step 4, or in the current shell execution environment, or both

If the command name is a standard utility implemented as a function (see XBD Section 4.22), the effect of variable assignments shall be as if the utility was not implemented as a function.

If the command name is a special built-in utility, variable assignments shall affect the current execution environment. Unless the *set* **−a** option is on (see *set*), it is unspecified:

- ‡ Whether or not the variables gain the *export* attribute during the execution of the special built-in utility
- ‡ Whether or not *export* attributes gained as a result of the variable assignments persist after the completion of the special built-in utility

If the command name is a function that is not a standard utility implemented as a function, variable assignments shall affect the current execution environment during the execution of the function. It is unspecified:

- ‡ Whether or not the variable assignments persist after the completion of the function
- ‡ Whether or not the variables gain the *export* attribute during the execution of the function
- ‡ Whether or not *export* attributes gained as a result of the variable assignments persist after the completion of the function (if variable assignments persist after the completion of the function)

If any of the variable assignments attempt to assign a value to a variable for which the *readonly* attribute is set in the current shell environment (regardless of whether the assignment is made in that environment), a variable assignment error shall occur. See Section 2.8.1 for the consequences of these errors.

If there is no command name, any redirections shall be performed in a subshell environment; it is unspecified whether this subshell environment is the same one as that used for a command substitution within the command. (To affect the current execution environment, see the *exec* special built-in.) If any of the redirections performed in the current shell execution environment fail, the command shall immediately fail with an exit status greater than zero, and the shell shall write an error message indicating the failure. See Section 2.8.1 for the consequences of these failures on interactive and non-interactive shells.

If there is a command name, execution shall continue as described in Section 2.9.1.1. If there is no command name, but the command contained a command substitution, the command shall complete with the exit status of the last command substitution performed. Otherwise, the command shall complete with a zero exit status.

75545 *2.9.1.1 Command Search and Execution*

75546 If a simple command results in a command name and an optional list of arguments, the
75547 following actions shall be performed:

75548 1. If the command name does not contain any <slash> characters, the first successful step in
75549 the following sequence shall occur:

75550 a. If the command name matches the name of a special built-in utility, that special
75551 built-in utility shall be invoked.

75552 b. If the command name matches the name of a utility listed in the following table,
75553 the results are unspecified.

alloc	*comparguments*	*comptry*	*history*	*pushd*
autoload	*compcall*	*compvalues*	*hist*	*readarray*
bind	*compctl*	*declare*	*let*	*repeat*
bindkey	*compdescribe*	*dirs*	*local*	*savehistory*
builtin	*compfiles*	*disable*	*login*	*source*
bye	*compgen*	*disown*	*logout*	*shopt*
caller	*compgroups*	*dosh*	*map*	*stop*
cap	*complete*	*echotc*	*mapfile*	*suspend*
chdir	*compquote*	*echoti*	*popd*	*typeset*
clone	*comptags*	*help*	*print*	*whence*

75564 c. If the command name matches the name of a function known to this shell, the
75565 function shall be invoked as described in Section 2.9.5. If the implementation has
75566 provided a standard utility in the form of a function, it shall not be recognized at
75567 this point. It shall be invoked in conjunction with the path search in step 1e.

75568 XSI d. If the command name matches the name of the *type* or *ulimit* utility, or of a utility
75569 listed in the following table, that utility shall be invoked.

alias	*false*	*hash*	*pwd*	*unalias*
bg	*fc*	*jobs*	*read*	*wait*
cd	*fg*	*kill*	*true*	
command	*getopts*	*newgrp*	*umask*	

75574 e. Otherwise, the command shall be searched for using the *PATH* environment
75575 variable as described in XBD Chapter 8:

75576 i. If the search is successful:

75577 a. If the system has implemented the utility as a regular built-in or as a
75578 shell function, it shall be invoked at this point in the path search.

75579 b. Otherwise, the shell executes the utility in a separate utility
75580 environment (see Section 2.12) with actions equivalent to calling the
75581 *execl*( ) function as defined in the System Interfaces volume of
75582 POSIX.1-2017 with the *path* argument set to the pathname resulting
75583 from the search, *arg*0 set to the command name, and the remaining
75584 *execl*( ) arguments set to the command arguments (if any) and the
75585 null terminator.

75586 If the *execl*( ) function fails due to an error equivalent to the
75587 [ENOEXEC] error defined in the System Interfaces volume of
75588 POSIX.1-2017, the shell shall execute a command equivalent to
75589 having a shell invoked with the pathname resulting from the search
75590 as its first operand, with any remaining arguments passed to the new

shell, except that the value of "$0" in the new shell may be set to the command name. If the executable file is not a text file, the shell may bypass this command execution. In this case, it shall write an error message, and shall return an exit status of 126.

It is unspecified whether environment variables that were passed to the shell when it was invoked, but were not used to initialize shell variables (see Section 2.5.3) because they had invalid names, are included in the environment passed to *execl*( ) and (if *execl*( ) fails as described above) to the new shell.

Once a utility has been searched for and found (either as a result of this specific search or as part of an unspecified shell start-up activity), an implementation may remember its location and need not search for the utility again unless the *PATH* variable has been the subject of an assignment. If the remembered location fails for a subsequent invocation, the shell shall repeat the search to find the new location for the utility, if any.

ii. If the search is unsuccessful, the command shall fail with an exit status of 127 and the shell shall write an error message.

2. If the command name contains at least one <slash>, the shell shall execute the utility in a separate utility environment with actions equivalent to calling the *execl*( ) function defined in the System Interfaces volume of POSIX.1-2017 with the *path* and *arg*0 arguments set to the command name, and the remaining *execl*( ) arguments set to the command arguments (if any) and the null terminator.

   If the *execl*( ) function fails due to an error equivalent to the [ENOEXEC] error, the shell shall execute a command equivalent to having a shell invoked with the command name as its first operand, with any remaining arguments passed to the new shell. If the executable file is not a text file, the shell may bypass this command execution. In this case, it shall write an error message and shall return an exit status of 126.

   It is unspecified whether environment variables that were passed to the shell when it was invoked, but were not used to initialize shell variables (see Section 2.5.3) because they had invalid names, are included in the environment passed to *execl*( ) and (if *execl*( ) fails as described above) to the new shell.

If the utility would be executed with file descriptor 0, 1, or 2 closed, implementations may execute the utility with the file descriptor open to an unspecified file. If a standard utility or a conforming application is executed with file descriptor 0 not open for reading or with file descriptor 1 or 2 not open for writing, the environment in which the utility or application is executed shall be deemed non-conforming, and consequently the utility or application might not behave as described in this standard.

2.9.2 Pipelines

A *pipeline* is a sequence of one or more commands separated by the control operator '|'. For each command but the last, the shell shall connect the standard output of the command to the standard input of the next command as if by creating a pipe and passing the write end of the pipe as the standard output of the command and the read end of the pipe as the standard input of the next command.

The format for a pipeline is:

[!] *command1* **[** | *command2* **...]**

If the pipeline begins with the reserved word **!** and *command1* is a subshell command, the application shall ensure that the **(** operator at the beginning of *command1* is separated from the **!** by one or more <blank> characters. The behavior of the reserved word **!** immediately followed by the **(** operator is unspecified.

The standard output of *command1* shall be connected to the standard input of *command2*. The standard input, standard output, or both of a command shall be considered to be assigned by the pipeline before any redirection specified by redirection operators that are part of the command (see Section 2.7).

If the pipeline is not in the background (see Section 2.9.3.1), the shell shall wait for the last command specified in the pipeline to complete, and may also wait for all commands to complete.

Exit Status

If the pipeline does not begin with the **!** reserved word, the exit status shall be the exit status of the last command specified in the pipeline. Otherwise, the exit status shall be the logical NOT of the exit status of the last command. That is, if the last command returns zero, the exit status shall be 1; if the last command returns greater than zero, the exit status shall be zero.

2.9.3 Lists

An *AND-OR list* is a sequence of one or more pipelines separated by the operators `"&&"` and `"||"`.

A *list* is a sequence of one or more AND-OR lists separated by the operators `';'` and `'&'`.

The operators `"&&"` and `"||"` shall have equal precedence and shall be evaluated with left associativity. For example, both of the following commands write solely **bar** to standard output:

```
false && echo foo || echo bar
true || echo foo && echo bar
```

A `';'` separator or a `';'` or <newline> terminator shall cause the preceding AND-OR list to be executed sequentially; an `'&'` separator or terminator shall cause asynchronous execution of the preceding AND-OR list.

The term ``compound-list'' is derived from the grammar in Section 2.10; it is equivalent to a sequence of *lists*, separated by <newline> characters, that can be preceded or followed by an arbitrary number of <newline> characters.

Examples

The following is an example that illustrates <newline> characters in compound-lists:

```
while
    # a couple of <newline>s

    # a list
    date && who || ls; cat file
    # a couple of <newline>s

    # another list
    wc file > output & true

do
    # 2 lists
```

```
        ls
        cat file
done
```

2.9.3.1 Asynchronous Lists

If a command is terminated by the control operator <ampersand> ('&'), the shell shall execute the command asynchronously in a subshell. This means that the shell shall not wait for the command to finish before executing the next command.

The format for running a command in the background is:

command1 & [*command2* & ...]

If job control is disabled (see *set*, –**m**), the standard input for an asynchronous list, before any explicit redirections are performed, shall be considered to be assigned to a file that has the same properties as **/dev/null**. This shall not happen if job control is enabled. In all cases, explicit redirection of standard input shall override this activity.

When an element of an asynchronous list (the portion of the list ended by an <ampersand>, such as *command1*, above) is started by the shell, the process ID of the last command in the asynchronous list element shall become known in the current shell execution environment; see Section 2.12. This process ID shall remain known until:

1. The command terminates and the application waits for the process ID.
2. Another asynchronous list is invoked before "$!" (corresponding to the previous asynchronous list) is expanded in the current execution environment.

The implementation need not retain more than the {CHILD_MAX} most recent entries in its list of known process IDs in the current shell execution environment.

Exit Status

The exit status of an asynchronous list shall be zero.

2.9.3.2 Sequential Lists

Commands that are separated by a <semicolon> (';') shall be executed sequentially.

The format for executing commands sequentially shall be:

command1 [; *command2*] ...

Each command shall be expanded and executed in the order specified.

Exit Status

The exit status of a sequential list shall be the exit status of the last command in the list.

2.9.3.3 AND Lists

The control operator "&&" denotes an AND list. The format shall be:

command1 [&& *command2*] ...

First *command1* shall be executed. If its exit status is zero, *command2* shall be executed, and so on, until a command has a non-zero exit status or there are no more commands left to execute. The

75713 commands are expanded only if they are executed.

75714 **Exit Status**

75715 The exit status of an AND list shall be the exit status of the last command that is executed in the
75716 list.

75717 *2.9.3.4 OR Lists*

75718 The control operator "||" denotes an OR List. The format shall be:

75719 *command1* **[** || *command2***]** **...**

75720 First, *command1* shall be executed. If its exit status is non-zero, *command2* shall be executed, and
75721 so on, until a command has a zero exit status or there are no more commands left to execute.

75722 **Exit Status**

75723 The exit status of an OR list shall be the exit status of the last command that is executed in the
75724 list.

75725 ## 2.9.4 Compound Commands

75726 The shell has several programming constructs that are ``compound commands'', which provide
75727 control flow for commands. Each of these compound commands has a reserved word or control
75728 operator at the beginning, and a corresponding terminator reserved word or operator at the end.
75729 In addition, each can be followed by redirections on the same line as the terminator. Each
75730 redirection shall apply to all the commands within the compound command that do not
75731 explicitly override that redirection.

75732 *2.9.4.1 Grouping Commands*

75733 The format for grouping commands is as follows:

75734 (*compound-list*) Execute *compound-list* in a subshell environment; see Section 2.12.
75735 Variable assignments and built-in commands that affect the environment
75736 shall not remain in effect after the list finishes.

75737 If a character sequence beginning with "((" would be parsed by the shell
75738 as an arithmetic expansion if preceded by a '$', shells which implement
75739 an extension whereby "((*expression*))" is evaluated as an arithmetic
75740 expression may treat the "((" as introducing as an arithmetic evaluation
75741 instead of a grouping command. A conforming application shall ensure
75742 that it separates the two leading '(' characters with white space to
75743 prevent the shell from performing an arithmetic evaluation.

75744 { *compound-list* ; } Execute *compound-list* in the current process environment. The semicolon
75745 shown here is an example of a control operator delimiting the } reserved
75746 word. Other delimiters are possible, as shown in Section 2.10; a
75747 <newline> is frequently used.

75748 **Exit Status**

75749 The exit status of a grouping command shall be the exit status of *compound-list*.

75750 *2.9.4.2 The for Loop*

75751 The **for** loop shall execute a sequence of commands for each member in a list of *items*. The **for**
75752 loop requires that the reserved words **do** and **done** be used to delimit the sequence of
75753 commands.

75754 The format for the **for** loop is as follows:

```
75755 for name [ in [word ... ]]
75756 do
75757     compound-list
75758 done
```

75759 First, the list of words following **in** shall be expanded to generate a list of items. Then, the
75760 variable *name* shall be set to each item, in turn, and the *compound-list* executed each time. If no
75761 items result from the expansion, the *compound-list* shall not be executed. Omitting:

75762 `in word ...`

75763 shall be equivalent to:

75764 `in "$@"`

75765 **Exit Status**

75766 The exit status of a **for** command shall be the exit status of the last command that executes. If
75767 there are no items, the exit status shall be zero.

75768 *2.9.4.3 Case Conditional Construct*

75769 The conditional construct **case** shall execute the *compound-list* corresponding to the first one of
75770 several *patterns* (see Section 2.13) that is matched by the string resulting from the tilde
75771 expansion, parameter expansion, command substitution, arithmetic expansion, and quote
75772 removal of the given word. The reserved word **in** shall denote the beginning of the patterns to
75773 be matched. Multiple patterns with the same *compound-list* shall be delimited by the `'|'`
75774 symbol. The control operator `')'` terminates a list of patterns corresponding to a given action.
75775 The *compound-list* for each list of patterns, with the possible exception of the last, shall be
75776 terminated with `";;"`. The **case** construct terminates with the reserved word **esac** (**case**
75777 reversed).

75778 The format for the **case** construct is as follows:

```
75779 case word in
75780     [(] pattern1 ) compound-list ;;
75781     [[(] pattern[ | pattern] ... ) compound-list ;;] ...
75782     [[(] pattern[ | pattern] ... ) compound-list]
75783 esac
```

75784 The `";;"` is optional for the last *compound-list*.

75785 In order from the beginning to the end of the **case** statement, each *pattern* that labels a *compound-*
75786 *list* shall be subjected to tilde expansion, parameter expansion, command substitution, and
75787 arithmetic expansion, and the result of these expansions shall be compared against the
75788 expansion of *word*, according to the rules described in Section 2.13 (which also describes the

effect of quoting parts of the pattern). After the first match, no more patterns shall be expanded, and the *compound-list* shall be executed. The order of expansion and comparison of multiple *pattern*s that label a *compound-list* statement is unspecified.

Exit Status

The exit status of **case** shall be zero if no patterns are matched. Otherwise, the exit status shall be the exit status of the last command executed in the *compound-list*.

2.9.4.4 *The if Conditional Construct*

The **if** command shall execute a *compound-list* and use its exit status to determine whether to execute another *compound-list*.

The format for the **if** construct is as follows:

```
if compound-list
then
    compound-list
[elif compound-list
then
    compound-list] ...
[else
    compound-list]
fi
```

The **if** *compound-list* shall be executed; if its exit status is zero, the **then** *compound-list* shall be executed and the command shall complete. Otherwise, each **elif** *compound-list* shall be executed, in turn, and if its exit status is zero, the **then** *compound-list* shall be executed and the command shall complete. Otherwise, the **else** *compound-list* shall be executed.

Exit Status

The exit status of the **if** command shall be the exit status of the **then** or **else** *compound-list* that was executed, or zero, if none was executed.

2.9.4.5 *The while Loop*

The **while** loop shall continuously execute one *compound-list* as long as another *compound-list* has a zero exit status.

The format of the **while** loop is as follows:

```
while compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a non-zero exit status, the **while** command shall complete. Otherwise, the *compound-list-2* shall be executed, and the process shall repeat.

Exit Status

The exit status of the **while** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.4.6 *The until Loop*

The **until** loop shall continuously execute one *compound-list* as long as another *compound-list* has a non-zero exit status.

The format of the **until** loop is as follows:

```
until compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a zero exit status, the **until** command completes. Otherwise, the *compound-list-2* shall be executed, and the process repeats.

Exit Status

The exit status of the **until** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.5 Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a ``function definition command''.

The format of a function definition command is as follows:

```
fname ( ) compound-command [io-redirect ...]
```

The function is named *fname*; the application shall ensure that it is a name (see XBD Section 3.235) and that it is not the name of a special built-in utility. An implementation may allow other characters in a function name as an extension. The implementation shall maintain separate name spaces for functions and variables.

The argument *compound-command* represents a compound command, as described in Section 2.9.4.

When the function is declared, none of the expansions in Section 2.6 shall be performed on the text in *compound-command* or *io-redirect*; all expansions shall be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* shall be performed during the execution of the function itself, not the function definition. See Section 2.8.1 for the consequences of failures of these operations on interactive and non-interactive shells.

When a function is executed, it shall have the syntax-error properties described for special built-in utilities in the first item in the enumerated list at the beginning of Section 2.14.

The *compound-command* shall be executed whenever the function name is specified as the name of a simple command (see Section 2.9.1.1). The operands to the command temporarily shall become the positional parameters during the execution of the *compound-command*; the special parameter `'#'` also shall be changed to reflect the number of operands. The special parameter 0 shall be unchanged. When the function completes, the values of the positional parameters and

the special parameter '#' shall be restored to the values they had before the function was executed. If the special built-in *return* (see *return*) is executed in the *compound-command*, the function completes and execution shall resume with the next command after the function call.

Exit Status

The exit status of a function definition shall be zero if the function was declared successfully; otherwise, it shall be greater than zero. The exit status of a function invocation shall be the exit status of the last command executed by the function.

2.10 Shell Grammar

The following grammar defines the Shell Command Language. This formal syntax shall take precedence over the preceding text syntax description.

2.10.1 Shell Grammar Lexical Conventions

The input language to the shell must be first recognized at the character level. The resulting tokens shall be classified by their immediate context according to the following rules (applied in order). These rules shall be used to determine what a ``token'' is that is subject to parsing at the token level. The rules for token recognition in Section 2.3 shall apply.

1. If the token is an operator, the token identifier for that operator shall result.
2. If the string consists solely of digits and the delimiter character is one of '<' or '>', the token identifier **IO_NUMBER** shall be returned.
3. Otherwise, the token identifier **TOKEN** results.

Further distinction on **TOKEN** is context-dependent. It may be that the same **TOKEN** yields **WORD**, a **NAME**, an **ASSIGNMENT_WORD**, or one of the reserved words below, dependent upon the context. Some of the productions in the grammar below are annotated with a rule number from the following list. When a **TOKEN** is seen where one of those annotated productions could be used to reduce the symbol, the applicable rule shall be applied to convert the token identifier type of the **TOKEN** to a token identifier acceptable at that point in the grammar. The reduction shall then proceed based upon the token identifier type yielded by the rule applied. When more than one rule applies, the highest numbered rule shall apply (which in turn may refer to another rule). (Note that except in rule 7, the presence of an '=' in the token has no effect.)

The **WORD** tokens shall have the word expansion rules applied to them immediately before the associated command is executed, not at the time the command is parsed.

2.10.2 Shell Grammar Rules

1. [Command Name]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, the token **WORD** shall be returned. Also, if the parser is in any state where only a reserved word could be the next correct token, proceed as above.

   Note: Because at this point <quotation-mark> characters are retained in the token, quoted strings cannot be recognized as reserved words. This rule also implies that reserved words are not recognized except in certain positions in the input, such as after a

<newline> or <semicolon>; the grammar presumes that if the reserved word is intended, it is properly delimited by the user, and does not attempt to reflect that requirement directly. Also note that line joining is done before tokenization, as described in Section 2.2.1, so escaped <newline> characters are already removed at this point.

Rule 1 is not directly referenced in the grammar, but is referred to by other rules, or applies globally.

2. [Redirection to or from filename]

   The expansions specified in Section 2.7 shall occur. As specified there, exactly one field can result (or the result is unspecified), and there are additional requirements on pathname expansion.

3. [Redirection from here-document]

   Quote removal shall be applied to the word to determine the delimiter that is used to find the end of the here-document that begins after the next <newline>.

4. [Case statement termination]

   When the **TOKEN** is exactly the reserved word **esac**, the token identifier for **esac** shall result. Otherwise, the token **WORD** shall be returned.

5. [**NAME** in **for**]

   When the **TOKEN** meets the requirements for a name (see XBD Section 3.235), the token identifier **NAME** shall result. Otherwise, the token **WORD** shall be returned.

6. [Third word of **for** and **case**]

   a. [**case** only]

      When the **TOKEN** is exactly the reserved word **in**, the token identifier for **in** shall result. Otherwise, the token **WORD** shall be returned.

   b. [**for** only]

      When the **TOKEN** is exactly the reserved word **in** or **do**, the token identifier for **in** or **do** shall result, respectively. Otherwise, the token **WORD** shall be returned.

   (For a. and b.: As indicated in the grammar, a *linebreak* precedes the tokens **in** and **do**. If <newline> characters are present at the indicated location, it is the token after them that is treated in this fashion.)

7. [Assignment preceding command name]

   a. [When the first word]

      If the **TOKEN** does not contain the character `'='`, rule 1 is applied. Otherwise, 7b shall be applied.

   b. [Not the first word]

      If the **TOKEN** contains an unquoted (as determined while applying rule 4 from Section 2.3) <equals-sign> character that is not part of an embedded parameter expansion, command substitution, or arithmetic expansion construct (as determined while applying rule 5 from Section 2.3):

      If the **TOKEN** begins with `'='`, then rule 1 shall be applied.

      If all the characters in the **TOKEN** preceding the first such <equals-sign> form a valid name (see XBD Section 3.235, on page 71), the token **ASSIGNMENT_WORD** shall be returned.

‡ Otherwise, it is unspecified whether rule 1 is applied or **ASSIGNMENT_WORD** is returned.

Otherwise, rule 1 shall be applied.

Assignment to the name within a returned **ASSIGNMENT_WORD** token shall occur as specified in Section 2.9.1.

8. [**NAME** in function]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, when the **TOKEN** meets the requirements for a name, the token identifier **NAME** shall result. Otherwise, rule 7 applies.

9. [Body of function]

   Word expansion and assignment shall never occur, even when required by the rules above, when this rule is being parsed. Each **TOKEN** that might either be expanded or have assignment applied to it shall instead be returned as a single **WORD** consisting only of characters that are exactly the token described in Section 2.3.

```

2.11 Signals and Error Handling

If job control is disabled (see the description of *set* −**m**) when the shell executes an asynchronous list, the commands in the list shall inherit from the shell a signal action of ignored (SIG_IGN) for the SIGINT and SIGQUIT signals. In all other cases, commands executed by the shell shall inherit the same signal actions as those inherited by the shell from its parent unless a signal action is modified by the *trap* special built-in (see *trap*)

When a signal for which a trap has been set is received while the shell is waiting for the completion of a utility executing a foreground command, the trap associated with that signal shall not be executed until after the foreground command has completed. When the shell is waiting, by means of the *wait* utility, for asynchronous commands to complete, the reception of a signal for which a trap has been set shall cause the *wait* utility to return immediately with an exit status >128, immediately after which the trap associated with that signal shall be taken.

If multiple signals are pending for the shell for which there are associated trap actions, the order of execution of trap actions is unspecified.

2.12 Shell Execution Environment

A shell execution environment consists of the following:

Open files inherited upon invocation of the shell, plus open files controlled by *exec*

Working directory as set by *cd*

File creation mask set by *umask*

XSI File size limit as set by *ulimit*

Current traps set by *trap*

Shell parameters that are set by variable assignment (see the *set* special built-in) or from the System Interfaces volume of POSIX.1-2017 environment inherited by the shell when it begins (see the *export* special built-in)

Shell functions; see Section 2.9.5

Options turned on at invocation or by *set*

Process IDs of the last commands in asynchronous lists known to this shell environment; see Section 2.9.3.1

Shell aliases; see Section 2.3.1

Utilities other than the special built-ins (see Section 2.14) shall be invoked in a separate environment that consists of the following. The initial value of these objects shall be the same as that for the parent shell, except as noted below.

Open files inherited on invocation of the shell, open files controlled by the *exec* special built-in plus any modifications, and additions specified by any redirections to the utility

Current working directory

File creation mask

If the utility is a shell script, traps caught by the shell shall be set to the default values and traps ignored by the shell shall be set to be ignored by the utility; if the utility is not a shell script, the trap actions (default or ignore) shall be mapped into the appropriate signal handling actions for the utility

Variables with the *export* attribute, along with those explicitly exported for the duration of the command, shall be passed to the utility environment variables

The environment of the shell process shall not be changed by the utility unless explicitly specified by the utility description (for example, *cd* and *umask*).

A subshell environment shall be created as a duplicate of the shell environment, except that signal traps that are not being ignored shall be set to the default action. Changes made to the subshell environment shall not affect the shell environment. Command substitution, commands that are grouped with parentheses, and asynchronous lists shall be executed in a subshell environment. Additionally, each command of a multi-command pipeline is in a subshell environment; as an extension, however, any or all commands in a pipeline may be executed in the current environment. All other commands shall be executed in the current shell environment.

2.13 Pattern Matching Notation

The pattern matching notation described in this section is used to specify patterns for matching strings in the shell. Historically, pattern matching notation is related to, but slightly different from, the regular expression notation described in XBD Chapter 9. For this reason, the description of the rules for this pattern matching notation are based on the description of regular expression notation, modified to account for the differences.

2.13.1 Patterns Matching a Single Character

The following patterns matching a single character shall match a single character: ordinary characters, special pattern characters, and pattern bracket expressions. The pattern bracket expression also shall match a single collating element. A <backslash> character shall escape the following character. The escaping <backslash> shall be discarded. If a pattern ends with an unescaped <backslash>, it is unspecified whether the pattern does not match anything or the pattern is treated as invalid.

An ordinary character is a pattern that shall match itself. It can be any character in the supported character set except for NUL, those special shell characters in Section 2.2 that require quoting, and the following three special pattern characters. Matching shall be based on the bit pattern used for encoding the character, not on the graphic representation of the character. If any character (ordinary, shell special, or pattern special) is quoted, that pattern shall match the character itself. The shell special characters always require quoting.

When unquoted and outside a bracket expression, the following three characters shall have special meaning in the specification of patterns:

76224 ? A <question-mark> is a pattern that shall match any character.

76225 * An <asterisk> is a pattern that shall match multiple characters, as described in Section
76226 2.13.2.

76227 [If an open bracket introduces a bracket expression as in XBD Section 9.3.5, except that the
76228 <exclamation-mark> character (`'!'`) shall replace the <circumflex> character (`'^'`) in its
76229 role in a non-matching list in the regular expression notation, it shall introduce a pattern
76230 bracket expression. A bracket expression starting with an unquoted <circumflex> character
76231 produces unspecified results. Otherwise, `'['` shall match the character itself.

76232 When pattern matching is used where shell quote removal is not performed (such as in the
76233 argument to the *find –name* primary when *find* is being called using one of the *exec* functions as
76234 defined in the System Interfaces volume of POSIX.1-2017, or in the *pattern* argument to the
76235 *fnmatch*() function), special characters can be escaped to remove their special meaning by
76236 preceding them with a <backslash> character. This escaping <backslash> is discarded. The
76237 sequence `"\\"` represents one literal <backslash>. All of the requirements and effects of quoting
76238 on ordinary, shell special, and special pattern characters shall apply to escaping in this context.

76239 ### 2.13.2 Patterns Matching Multiple Characters

76240 The following rules are used to construct patterns matching multiple characters from patterns
76241 matching a single character:

76242 1. The <asterisk> (`'*'`) is a pattern that shall match any string, including the null string.

76243 2. The concatenation of patterns matching a single character is a valid pattern that shall
76244 match the concatenation of the single characters or collating elements matched by each of
76245 the concatenated patterns.

76246 3. The concatenation of one or more patterns matching a single character with one or more
76247 <asterisk> characters is a valid pattern. In such patterns, each <asterisk> shall match a
76248 string of zero or more characters, matching the greatest possible number of characters
76249 that still allows the remainder of the pattern to match the string.

76250 ### 2.13.3 Patterns Used for Filename Expansion

76251 The rules described so far in Section 2.13.1 and Section 2.13.2 are qualified by the following rules
76252 that apply when pattern matching notation is used for filename expansion:

76253 1. The <slash> character in a pathname shall be explicitly matched by using one or more
76254 <slash> characters in the pattern; it shall neither be matched by the <asterisk> or
76255 <question-mark> special characters nor by a bracket expression. <slash> characters in the
76256 pattern shall be identified before bracket expressions; thus, a <slash> cannot be included
76257 in a pattern bracket expression used for filename expansion. If a <slash> character is
76258 found following an unescaped <left-square-bracket> character before a corresponding
76259 <right-square-bracket> is found, the open bracket shall be treated as an ordinary
76260 character. For example, the pattern `"a[b/c]d"` does not match such pathnames as **abd**
76261 or **a/d**. It only matches a pathname of literally **a[b/c]d**.

76262 2. If a filename begins with a <period> (`'.'`), the <period> shall be explicitly matched by
76263 using a <period> as the first character of the pattern or immediately following a <slash>
76264 character. The leading <period> shall not be matched by:

The <asterisk> or <question-mark> special characters

A bracket expression containing a non-matching list, such as `"[!a]"`, a range expression, such as `"[%–0]"`, or a character class expression, such as `"[[:punct:]]"`

It is unspecified whether an explicit <period> in a bracket expression matching list, such as `"[.abc]"`, can match a leading <period> in a filename.

3. Specified patterns shall be matched against existing filenames and pathnames, as appropriate. Each component that contains a pattern character shall require read permission in the directory containing that component. Any component, except the last, that does not contain a pattern character shall require search permission. For example, given the pattern:

   `/foo/bar/x*/bam`

   search permission is needed for directories **/** and **foo**, search and read permissions are needed for directory **bar**, and search permission is needed for each **x*** directory. If the pattern matches any existing filenames or pathnames, the pattern shall be replaced with those filenames and pathnames, sorted according to the collating sequence in effect in the current locale. If this collating sequence does not have a total ordering of all characters (see XBD Section 7.3.2, on page 147), any filenames or pathnames that collate equally should be further compared byte-by-byte using the collating sequence for the POSIX locale.

   Note: A future version of this standard may require the byte-by-byte further comparison described above.

   If the pattern contains an open bracket (`'['`) that does not introduce a bracket expression as in XBD Section 9.3.5, it is unspecified whether other unquoted pattern matching characters within the same slash-delimited component of the pattern retain their special meanings or are treated as ordinary characters. For example, the pattern `"a*[/b*"` may match all filenames beginning with `'b'` in the directory `"a*["` or it may match all filenames beginning with `'b'` in all directories with names beginning with `'a'` and ending with `'['`.

   If the pattern does not match any existing filenames or pathnames, the pattern string shall be left unchanged.

2.14 Special Built-In Utilities

The following ``special built-in'' utilities shall be supported in the shell command language. The output of each command, if any, shall be written to standard output, subject to the normal redirection and piping possible with all commands.

The term ``built-in'' implies that the shell can execute the utility directly and does not need to search for it. An implementation may choose to make any utility a built-in; however, the special built-in utilities described here differ from regular built-in utilities in two respects:

1. An error in a special built-in utility may cause a shell executing that utility to abort, while an error in a regular built-in utility shall not cause a shell executing that utility to abort. (See Section 2.8.1 for the consequences of errors on interactive and non-interactive shells.) If a special built-in utility encountering an error does not abort the shell, its exit value shall be non-zero.

76308 2. As described in Section 2.9.1, variable assignments preceding the invocation of a special
76309 built-in utility remain in effect after the built-in completes; this shall not be the case with a
76310 regular built-in or other utility.

76311 The special built-in utilities in this section need not be provided in a manner accessible via the
76312 *exec* family of functions defined in the System Interfaces volume of POSIX.1-2017.

76313 Some of the special built-ins are described as conforming to XBD Section 12.2. For those that are
76314 not, the requirement in Section 1.4 that `"--"` be recognized as a first argument to be discarded
76315 does not apply and a conforming application shall not use that argument.

76316 **NAME**

76317 break — exit from for, while, or until loop

76318 **SYNOPSIS**

76319 `break [n]`

76320 **DESCRIPTION**

76321 If *n* is specified, the *break* utility shall exit from the *n*th enclosing **for**, **while**, or **until** loop. If *n* is
76322 not specified, *break* shall behave as if *n* was specified as 1. Execution shall continue with the
76323 command immediately following the exited loop. The value of *n* is a positive decimal integer. If
76324 *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be exited. If
76325 there is no enclosing loop, the behavior is unspecified.

76326 A loop shall enclose a *break* or *continue* command if the loop lexically encloses the command. A
76327 loop lexically encloses a *break* or *continue* command if the command is:

76328 Executing in the same execution environment (see Section 2.12) as the compound-list of the
76329 loop's do-group (see Section 2.10.2), and

76330 Contained in a compound-list associated with the loop (either in the compound-list of the
76331 loop's do-group or, if the loop is a **while** or **until** loop, in the compound-list following the
76332 **while** or **until** reserved word), and

76333 Not in the body of a function whose function definition command (see Section 2.9.5) is
76334 contained in a compound-list associated with the loop.

76335 If *n* is greater than the number of lexically enclosing loops and there is a non-lexically enclosing
76336 loop in progress in the same execution environment as the *break* or *continue* command, it is
76337 unspecified whether that loop encloses the command.

76338 **OPTIONS**

76339 None.

76340 **OPERANDS**

76341 See the DESCRIPTION.

76342 **STDIN**

76343 Not used.

76344 **INPUT FILES**

76345 None.

76346 **ENVIRONMENT VARIABLES**

76347 None.

76348 **ASYNCHRONOUS EVENTS**

76349 Default.

76350 **STDOUT**

76351 Not used.

76352 **STDERR**

76353 The standard error shall be used only for diagnostic messages.

76354 **OUTPUT FILES**

76355 None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

0 Successful completion.

>0 The *n* value was not an unsigned decimal integer greater than or equal to 1.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

```
for i in *
do
    if test -d "$i"
    then break
    fi
done
```

The results of running the following example are unspecified: there are two loops in progress when the *break* command is executed, and they are in the same execution environment, but neither loop is lexically enclosing the *break* command. (There are no loops lexically enclosing the *continue* commands, either.)

```
foo() {
    for j in 1 2; do
        echo 'break 2' >/tmp/do_break
        echo "  sourcing /tmp/do_break ($j)..."
        # the behavior of the break from running the following command
        # results in unspecified behavior:
        . /tmp/do_break

        do_continue() { continue 2; }
        echo "  running do_continue ($j)..."
        # the behavior of the continue in the following function call
        # results in unspecified behavior (if execution reaches this
        # point):
        do_continue

        trap 'continue 2' USR1
        echo "  sending SIGUSR1 to self ($j)..."
        # the behavior of the continue in the trap invoked from the
        # following signal results in unspecified behavior (if
        # execution reaches this point):
        kill -s USR1 $$
        sleep 1
    done
}
for i in 1 2; do
    echo "running foo ($i)..."
    foo
done
```

RATIONALE

In early proposals, consideration was given to expanding the syntax of *break* and *continue* to refer to a label associated with the appropriate loop as a preferable alternative to the *n* method. However, this volume of POSIX.1-2017 does reserve the name space of command names ending with a <colon>. It is anticipated that a future implementation could take advantage of this and provide something like:

```
outofloop: for i in a b c d e
do
    for j in 0 1 2 3 4 5 6 7 8 9
    do
        if test -r "${i}${j}"
        then break outofloop
        fi
    done
done
```

and that this might be standardized after implementation experience is achieved.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0046 [842] is applied.

76429 **NAME**

76430 colon ‡’null utility

76431 **SYNOPSIS**

76432 `: [`*`argument`*`...]`

76433 **DESCRIPTION**

76434 This utility shall only expand command *argument*s. It is used when a command is needed, as in
76435 the **then** condition of an **if** command, but nothing is to be done by the command.

76436 **OPTIONS**

76437 None.

76438 **OPERANDS**

76439 See the DESCRIPTION.

76440 **STDIN**

76441 Not used.

76442 **INPUT FILES**

76443 None.

76444 **ENVIRONMENT VARIABLES**

76445 None.

76446 **ASYNCHRONOUS EVENTS**

76447 Default.

76448 **STDOUT**

76449 Not used.

76450 **STDERR**

76451 The standard error shall be used only for diagnostic messages.

76452 **OUTPUT FILES**

76453 None.

76454 **EXTENDED DESCRIPTION**

76455 None.

76456 **EXIT STATUS**

76457 Zero.

76458 **CONSEQUENCES OF ERRORS**

76459 Default.

76460 **APPLICATION USAGE**

76461 None.

76462 **EXAMPLES**

76463 `: ${X=abc}`
76464 `if  false`
76465 `then  :`
76466 `else  echo $X`
76467 `fi`
76468 **`abc`**

76469 As with any of the special built-ins, the null utility can also have variable assignments and
76470 redirections associated with it, such as:

76471 `x=y : > z`

which sets variable *x* to the value *y* (so that it persists after the null utility completes) and creates or truncates file **z**.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

76487 **NAME**

76488 continue ‡’continue for,while, or until loop

76489 **SYNOPSIS**

76490 `continue [`*n*`]`

76491 **DESCRIPTION**

76492 If *n* is specified, the *continue* utility shall return to the top of the *n*th enclosing **for**, **while**, or **until**
76493 loop. If *n* is not specified, *continue* shall behave as if *n* was specified as 1. Returning to the top of
76494 the loop involves repeating the condition list of a **while** or **until** loop or performing the next
76495 assignment of a **for** loop, and re-executing the loop if appropriate.

76496 The value of *n* is a positive decimal integer. If *n* is greater than the number of enclosing loops,
76497 the outermost enclosing loop shall be used. If there is no enclosing loop, the behavior is
76498 unspecified.

76499 The meaning of ``enclosing'' shall be as specified in the description of the *break* utility.

76500 **OPTIONS**

76501 None.

76502 **OPERANDS**

76503 See the DESCRIPTION.

76504 **STDIN**

76505 Not used.

76506 **INPUT FILES**

76507 None.

76508 **ENVIRONMENT VARIABLES**

76509 None.

76510 **ASYNCHRONOUS EVENTS**

76511 Default.

76512 **STDOUT**

76513 Not used.

76514 **STDERR**

76515 The standard error shall be used only for diagnostic messages.

76516 **OUTPUT FILES**

76517 None.

76518 **EXTENDED DESCRIPTION**

76519 None.

76520 **EXIT STATUS**

76521 0 Successful completion.

76522 >0 The *n* value was not an unsigned decimal integer greater than or equal to 1.

76523 **CONSEQUENCES OF ERRORS**

76524 Default.

APPLICATION USAGE

None.

EXAMPLES

```
for i in *
do
    if test -d "$i"
    then continue
    fi
    printf '"%s" is not a directory.\n' "$i"
done
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

The example is changed to use the *printf* utility rather than *echo*.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0046 [842] is applied.

NAME

dot — execute commands in the current environment

SYNOPSIS

```
. file
```

DESCRIPTION

The shell shall execute commands from the *file* in the current environment.

If *file* does not contain a <slash>, the shell shall use the search path specified by *PATH* to find the directory containing *file*. Unlike normal command search, however, the file searched for by the *dot* utility need not be executable. If no readable file is found, a non-interactive shell shall abort; an interactive shell shall write a diagnostic message to standard error, but this condition shall not be considered a syntax error.

OPTIONS

None.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

See the DESCRIPTION.

ENVIRONMENT VARIABLES

See the DESCRIPTION.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If no readable file was found or if the commands in the file could not be parsed, and the shell is interactive (and therefore does not abort; see Section 2.8.1), the exit status shall be non-zero. Otherwise, return the value of the last command executed, or a zero exit status if no command is executed.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

```
cat foobar
foo=hello bar=world
. ./foobar
echo $foo $bar
hello world
```

RATIONALE

Some older implementations searched the current directory for the *file*, even if the value of *PATH* disallowed it. This behavior was omitted from this volume of POSIX.1-2017 due to concerns about introducing the susceptibility to trojan horses that the user might be trying to avoid by leaving **dot** out of *PATH*.

The KornShell version of *dot* takes optional arguments that are set to the positional parameters. This is a valid extension that allows a *dot* script to behave identically to a function.

FUTURE DIRECTIONS

None.

Section 2.14, *return*

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-164 is applied.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0038 [114] and XCU/TC1-2008/0039 [214] are applied.

NAME

eval — construct command by concatenating arguments

SYNOPSIS

```
eval [argument...]
```

DESCRIPTION

The *eval* utility shall construct a command by concatenating *argument*s together, separating each with a <space> character. The constructed command shall be read and executed by the shell.

OPTIONS

None.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If there are no *argument*s, or only null *argument*s, *eval* shall return a zero exit status; otherwise, it shall return the exit status of the command defined by the string of concatenated *argument*s separated by <space> characters, or a non-zero exit status if the concatenation could not be parsed as a command and the shell is interactive (and therefore did not abort).

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *eval* is not required to recognize the `"--"` end of options delimiter, in cases where the argument(s) to *eval* might begin with `'-'` it is recommended that the first argument is prefixed by a string that will not alter the commands to be executed, such as a <space> character:

```
eval " $commands"
```

or:

```
eval " $(some_command)"
```

EXAMPLES

```
foo=10 x=foo
y='$'$x
echo $y
$foo
eval y='$'$x
echo $y
10
```

RATIONALE

This standard allows, but does not require, *eval* to recognize `"--"`. Although this means applications cannot use `"--"` to protect against options supported as an extension (or errors reported for unsupported options), the nature of the *eval* utility is such that other means can be used to provide this protection (see APPLICATION USAGE above).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0040 [114], XCU/TC1-2008/0041 [163], and XCU/TC1-2008/0042 [163] are applied.

NAME

exec ‡'execute commands and open, close, or copy file descriptors

SYNOPSIS

```
exec [command [argument...]]
```

DESCRIPTION

The *exec* utility shall open, close, and/or copy file descriptors as specified by any redirections as part of the command.

If *exec* is specified without *command* or *argument*s, and any file descriptors with numbers greater than 2 are opened with associated redirection statements, it is unspecified whether those file descriptors remain open when the shell invokes another utility. Scripts concerned that child shells could misuse open file descriptors can always close them explicitly, as shown in one of the following examples.

If *exec* is specified with *command*, it shall replace the shell with *command* without creating a new process. If *argument*s are specified, they shall be arguments to *command*. Redirection affects the current shell execution environment.

OPTIONS

None.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *command* is specified, *exec* shall not return to the shell; rather, the exit status of the process shall be the exit status of the program implementing *command*, which overlaid the shell. If *command* is not found, the exit status shall be 127. If *command* is found, but it is not an executable utility, the exit status shall be 126. If a redirection error occurs (see Section 2.8.1), the shell shall exit with a value in the range 1–125. Otherwise, *exec* shall return a zero exit status.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

Open *readfile* as file descriptor 3 for reading:

```
exec 3< readfile
```

Open *writefile* as file descriptor 4 for writing:

```
exec 4> writefile
```

Make file descriptor 5 a copy of file descriptor 0:

```
exec 5<&0
```

Close file descriptor 3:

```
exec 3<&-
```

Cat the file **maggie** by replacing the current shell with the *cat* utility:

```
exec cat maggie
```

RATIONALE

Most historical implementations were not conformant in that:

```
foo=bar exec cmd
```

did not pass **foo** to **cmd**.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

exit ‡'cause the shell to exit

SYNOPSIS

```
exit [n]
```

DESCRIPTION

The *exit* utility shall cause the shell to exit from its current execution environment with the exit status specified by the unsigned decimal integer *n*. If the current execution environment is a subshell environment, the shell shall exit from the subshell environment with the specified exit status and continue in the environment from which that subshell environment was invoked; otherwise, the shell utility shall terminate with the specified exit status. If *n* is specified, but its value is not between 0 and 255 inclusively, the exit status is undefined.

A *trap* on **EXIT** shall be executed before the shell terminates, except when the *exit* utility is invoked in that *trap* itself, in which case the shell shall exit immediately.

OPTIONS

None.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The exit status shall be *n*, if specified, except that the behavior is unspecified if *n* is not an unsigned decimal integer or is greater than 255. Otherwise, the value shall be the exit value of the last command executed, or zero if no command was executed. When *exit* is executed in a *trap* action, the last command is considered to be the command that executed immediately preceding the *trap* action.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

Exit with a *true* value:

```
exit 0
```

Exit with a *false* value:

```
exit 1
```

Propagate error handling from within a subshell:

```
(
    command1 || exit 1
    command2 || exit 1
    exec command3
) > outputfile || exit 1
echo "outputfile created successfully"
```

RATIONALE

As explained in other sections, certain exit status values have been reserved for special uses and should be used by applications only for those purposes:

126 A file to be executed was found, but it was not an executable utility.

127 A utility to be executed was not found.

>128 A command was interrupted by a signal.

The behavior of *exit* when given an invalid argument or unknown option is unspecified, because of differing practices in the various historical implementations. A value larger than 255 might be truncated by the shell, and be unavailable even to a parent process that uses *waitid*() to get the full exit value. It is recommended that implementations that detect any usage error should cause a non-zero exit status (or, if the shell is interactive and the error does not cause the shell to abort, store a non-zero value in `"$?"`), but even this was not done historically in all shells.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0047 [717], XCU/TC2-2008/0048 [960], XCU/TC2-2008/0049 [717], and XCU/TC2-2008/0050 [960] are applied.

NAME

export ‡'set the export attribute for variables

SYNOPSIS

```
export name[=word]...
export -p
```

DESCRIPTION

The shell shall give the *export* attribute to the variables corresponding to the specified *name*s, which shall cause them to be in the environment of subsequently executed commands. If the name of a variable is followed by =*word*, then the value of that variable shall be set to *word*.

The *export* special built-in shall support XBD Section 12.2.

When **-p** is specified, *export* shall write to the standard output the names and values of all exported variables, in the following format:

```
"export %s=%s\n", <name>, <value>
```

if *name* is set, and:

```
"export %s\n", <name>
```

if *name* is unset.

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results, except:

1. Read-only variables with values cannot be reset.
2. Variables that were unset at the time they were output need not be reset to the unset state if a value is assigned to the variable between the time the state was saved and the time at which the saved output is reinput to the shell.

When no arguments are given, the results are unspecified.

OPTIONS

See the DESCRIPTION.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the DESCRIPTION.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

0 All *name* operands were successfully exported.

>0 At least one *name* could not be exported, or the **−p** option was specified and an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that, unless *X* was previously marked readonly, the value of `"$?"` after:

```
export X=$(false)
```

will be 0 (because *export* successfully set *X* to the empty string) and that execution continues, even if *set* **−e** is in effect. In order to detect command substitution failures, a user must separate the assignment from the export, as in:

```
X=$(false)
export X
```

EXAMPLES

Export *PWD* and *HOME* variables:

```
export PWD HOME
```

Set and export the *PATH* variable:

```
export PATH=/local/bin:$PATH
```

Save and restore all exported variables:

```
export −p > temp-file
unset a lot of variables
... processing
. temp-file
```

RATIONALE

Some historical shells use the no-argument case as the functional equivalent of what is required here with **−p**. This feature was left unspecified because it is not historical practice in all shells, and some scripts may rely on the now-unspecified results on their implementations. Attempts to specify the **−p** output as the default case were unsuccessful in achieving consensus. The **−p** option was added to allow portable access to the values that can be saved and then later restored using; for example, a *dot* script.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the format when a variable is unset.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/6 is applied, adding the following text to the end of the first paragraph of the DESCRIPTION: ``If the name of a variable is followed by =*word*, then the value of that variable shall be set to *word*.''. The reason for this change is that the SYNOPSIS for *export* includes:

```
export name[=word]...
```

but the meaning of the optional ``=*word*'' is never explained in the text.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0043 [352] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0051 [654] and XCU/TC2-2008/0052 [960] are applied.

NAME

readonly — set the readonly attribute for variables

SYNOPSIS

```
readonly name[=word]...
readonly -p
```

DESCRIPTION

The variables whose *name*s are specified shall be given the *readonly* attribute. The values of variables with the *readonly* attribute cannot be changed by subsequent assignment, nor can those variables be unset by the *unset* utility. If the name of a variable is followed by =*word*, then the value of that variable shall be set to *word*.

The *readonly* special built-in shall support XBD Section 12.2.

When **−p** is specified, *readonly* writes to the standard output the names and values of all read-only variables, in the following format:

```
"readonly %s=%s\n", <name>, <value>
```

if *name* is set, and

```
"readonly %s\n", <name>
```

if *name* is unset.

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same value and *readonly* attribute-setting results in a shell execution environment in which:

1. Variables with values at the time they were output do not have the *readonly* attribute set.
2. Variables that were unset at the time they were output do not have a value at the time at which the saved output is reinput to the shell.

When no arguments are given, the results are unspecified.

OPTIONS

See the DESCRIPTION.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the DESCRIPTION.

76965 **STDERR**

76966 The standard error shall be used only for diagnostic messages.

76967 **OUTPUT FILES**

76968 None.

76969 **EXTENDED DESCRIPTION**

76970 None.

76971 **EXIT STATUS**

76972 0 All *name* operands were successfully marked readonly.

76973 >0 At least one *name* could not be marked readonly, or the **−p** option was specified and an error
76974 occurred.

76975 **CONSEQUENCES OF ERRORS**

76976 Default.

76977 **APPLICATION USAGE**

76978 None.

76979 **EXAMPLES**

76980
```
readonly HOME PWD
```

76981 **RATIONALE**

76982 Some historical shells preserve the *readonly* attribute across separate invocations. This volume of
76983 POSIX.1-2017 allows this behavior, but does not require it.

76984 The **−p** option allows portable access to the values that can be saved and then later restored
76985 using, for example, a *dot* script. Also see the RATIONALE for *export* for a description of the no-
76986 argument and **−p** output cases and a related example.

76987 Read-only functions were considered, but they were omitted as not being historical practice or
76988 particularly useful. Furthermore, functions must not be read-only across invocations to preclude
76989 ``spoofing'' (spoofing is the term for the practice of creating a program that acts like a well-
76990 known utility with the intent of subverting the real intent of the user) of administrative or
76991 security-relevant (or security-conscious) shell scripts.

76992 **FUTURE DIRECTIONS**

76993 None.

76994 **SEE ALSO**

76995 Section 2.14

76996 XBD Section 12.2

76997 **CHANGE HISTORY**

76998 **Issue 6**

76999 IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the format when a variable is unset.

77000 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
77001 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
77002 behavior is intended.

77003 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/7 is applied, adding the following text to
77004 the end of the first paragraph of the DESCRIPTION: ``If the name of a variable is followed by
77005 *=word*, then the value of that variable shall be set to *word*.''. The reason for this change is that the
77006 SYNOPSIS for *readonly* includes:

77007 `readonly name[=word]...`

77008 but the meaning of the optional ``=*word*'' is never explained in the text.

77009 **Issue 7**

77010 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0052 [960] is applied.

77011 **NAME**

77012 return — return from a function or dot script

77013 **SYNOPSIS**

77014 `return [`*n*`]`

77015 **DESCRIPTION**

77016 The *return* utility shall cause the shell to stop executing the current function or *dot* script. If the
77017 shell is not currently executing a function or *dot* script, the results are unspecified.

77018 **OPTIONS**

77019 None.

77029 Default.

77030 **STDOUT**

77031 Not used.

77032 **STDERR**

77033 The standard error shall be used only for diagnostic messages.

77034 **OUTPUT FILES**

77035 None.

77036 **EXTENDED DESCRIPTION**

77037 None.

77038 **EXIT STATUS**

77039 The value of the special parameter `'?'` shall be set to *n*, an unsigned decimal integer, or to the
77040 exit status of the last command executed if *n* is not specified. If *n* is not an unsigned decimal
77041 integer, or is greater than 255, the results are unspecified. When *return* is executed in a *trap*
77042 action, the last command is considered to be the command that executed immediately preceding
77043 the *trap* action.

77044 **CONSEQUENCES OF ERRORS**

77045 Default.

77046 **APPLICATION USAGE**

77047 None.

77048 **EXAMPLES**

77049 None.

77050 **RATIONALE**

77051 The behavior of *return* when not in a function or *dot* script differs between the System V shell
77052 and the KornShell. In the System V shell this is an error, whereas in the KornShell, the effect is
77053 the same as *exit*.

The results of returning a number greater than 255 are undefined because of differing practices in the various historical implementations. Some shells AND out all but the low-order 8 bits; others allow larger values, but not of unlimited size.

See the discussion of appropriate exit status values under *exit*.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0044 [214] and XCU/TC1-2008/0045 [214] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0052 [960] is applied.

77071 **NAME**

77072 set ‡'set or unset options and positional parameters

77073 **SYNOPSIS**

77074 `set [−abCefhmnuvx] [−o option] [argument...]`

77075 `set [+abCefhmnuvx] [+o option] [argument...]`

77076 `set −− [argument...]`

77077 `set −o`

77078 `set +o`

77079 **DESCRIPTION**

77080 If no *option*s or *argument*s are specified, *set* shall write the names and values of all shell variables
77081 in the collation sequence of the current locale. Each *name* shall start on a separate line, using the
77082 format:

77083 `"%s=%s\n", <name>, <value>`

77084 The *value* string shall be written with appropriate quoting; see the description of shell quoting in
77085 Section 2.2. The output shall be suitable for reinput to the shell, setting or resetting, as far as
77086 possible, the variables that are currently set; read-only variables cannot be reset.

77087 When options are specified, they shall set or unset attributes of the shell, as described below.
77088 When *argument*s are specified, they cause positional parameters to be set or unset, as described
77089 below. Setting or unsetting attributes and positional parameters are not necessarily related
77090 actions, but they can be combined in a single invocation of *set*.

77091 The *set* special built-in shall support XBD Section 12.2 except that options can be specified with
77092 either a leading <hyphen-minus> (meaning enable the option) or <plus-sign> (meaning disable
77093 it) unless otherwise specified.

77094 Implementations shall support the options in the following list in both their <hyphen-minus>
77095 and <plus-sign> forms. These options can also be specified as options to *sh*.

77096 **−a** When this option is on, the *export* attribute shall be set for each variable to which an
77097 assignment is performed; see XBD Section 4.23. If the assignment precedes a utility name in
77098 a command, the *export* attribute shall not persist in the current execution environment after
77099 the utility completes, with the exception that preceding one of the special built-in utilities
77100 causes the *export* attribute to persist after the built-in has completed. If the assignment does
77101 not precede a utility name in the command, or if the assignment is a result of the operation
77102 of the *getopts* or *read* utilities, the *export* attribute shall persist until the variable is unset.

77103 **−b** This option shall be supported if the implementation supports the User Portability Utilities
77104 option. It shall cause the shell to notify the user asynchronously of background job
77105 completions. The following message is written to standard error:

77106 `"[%d]%c %s%s\n", <job-number>, <current>, <status>, <job-name>`

77107 where the fields shall be as follows:

77108 <*current*> The character `'+'` identifies the job that would be used as a default for
77109 the *fg* or *bg* utilities; this job can also be specified using the *job_id* `"%+"` or
77110 `"%%"`. The character `'−'` identifies the job that would become the default
77111 if the current default job were to exit; this job can also be specified using
77112 the *job_id* `"%−"`. For other jobs, this field is a <space>. At most one job
77113 can be identified with `'+'` and at most one job can be identified with `'−'`.
77114 If there is any suspended job, then the current job shall be a suspended

77115 job. If there are at least two suspended jobs, then the previous job also
77116 shall be a suspended job.

77117 <*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*,
77118 and *kill* utilities. Using these utilities, the job can be identified by prefixing
77119 the job number with `'%'`.

77120 <*status*> Unspecified.

77121 <*job-name*> Unspecified.

77122 When the shell notifies the user a job has been completed, it may remove the job's process
77123 ID from the list of those known in the current shell execution environment; see Section
77124 2.9.3.1. Asynchronous notification shall not be enabled by default.

77125 **−C** (Uppercase C.) Prevent existing files from being overwritten by the shell's `'>'` redirection
77126 operator (see Section 2.7.2); the `">|"` redirection operator shall override this *noclobber*
77127 option for an individual file.

77128 **−e** When this option is on, when any command fails (for any of the reasons listed in Section
77129 2.8.1 or by returning an exit status greater than zero), the shell immediately shall exit, as if
77130 by executing the *exit* special built-in utility with no arguments, with the following
77131 exceptions:

77132 1. The failure of any individual command in a multi-command pipeline shall not cause
77133 the shell to exit. Only the failure of the pipeline itself shall be considered.

77134 2. The **−e** setting shall be ignored when executing the compound list following the
77135 **while**, **until**, **if**, or **elif** reserved word, a pipeline beginning with the **!** reserved word,
77136 or any command of an AND-OR list other than the last.

77137 3. If the exit status of a compound command other than a subshell command was the
77138 result of a failure while **−e** was being ignored, then **−e** shall not apply to this
77139 command.

77140 This requirement applies to the shell environment and each subshell environment
77141 separately. For example, in:

77142 ```
set -e; (false; echo one) | cat; echo two
```

77143 the *false* command causes the subshell to exit without executing `echo one`; however, `echo`
77144 `two` is executed because the exit status of the pipeline `(false; echo one) | cat` is
77145 zero.

77146 **−f** The shell shall disable pathname expansion.

77147 **−h** Locate and remember utilities invoked by functions as those functions are defined (the
77148 utilities are normally located when the function is executed).

77149 **−m** This option shall be supported if the implementation supports the User Portability Utilities
77150 option. All jobs shall be run in their own process groups. Immediately before the shell issues
77151 a prompt after completion of the background job, a message reporting the exit status of the
77152 background job shall be written to standard error. If a foreground job stops, the shell shall
77153 write a message to standard error to that effect, formatted as described by the *jobs* utility. In
77154 addition, if a job changes status other than exiting (for example, if it stops for input or
77155 output or is stopped by a SIGSTOP signal), the shell shall write a similar message
77156 immediately prior to writing the next prompt. This option is enabled by default for
77157 interactive shells.

  
```

77158 77159 **−n** The shell shall read commands but does not execute them; this can be used to check for shell script syntax errors. An interactive shell may ignore this option.

77160 **−o** Write the current settings of the options to standard output in an unspecified format.

77161 77162 **+o** Write the current option settings to standard output in a format that is suitable for reinput to the shell as commands that achieve the same options settings.

77163 **−o** *option*

77164 77165 77166 This option is supported if the system supports the User Portability Utilities option. It shall set various options, many of which shall be equivalent to the single option letters. The following values of *option* shall be supported:

77167 *allexport* Equivalent to **−a**.

77168 *errexit* Equivalent to **−e**.

77169 77170 77171 *ignoreeof* Prevent an interactive shell from exiting on end-of-file. This setting prevents accidental logouts when <control>-D is entered. A user shall explicitly *exit* to leave the interactive shell.

77172 77173 *monitor* Equivalent to **−m**. This option is supported if the system supports the User Portability Utilities option.

77174 *noclobber* Equivalent to **−C** (uppercase C).

77175 *noglob* Equivalent to **−f**.

77176 *noexec* Equivalent to **−n**.

77177 77178 *nolog* Prevent the entry of function definitions into the command history; see Command History List.

77179 *notify* Equivalent to **−b**.

77180 *nounset* Equivalent to **−u**.

77181 *verbose* Equivalent to **−v**.

77182 77183 77184 *vi* Allow shell command line editing using the built-in *vi* editor. Enabling *vi* mode shall disable any other command line editing mode provided as an implementation extension.

77185 It need not be possible to set *vi* mode on for certain block-mode terminals.

77186 *xtrace* Equivalent to **−x**.

77187 77188 77189 **−u** When the shell tries to expand an unset parameter other than the `'@'` and `'*'` special parameters, it shall write a message to standard error and the expansion shall fail with the consequences specified in Section 2.8.1.

77190 **−v** The shell shall write its input to standard error as it is read.

77191 77192 77193 **−x** The shell shall write to standard error a trace for each command after it expands the command and before it executes it. It is unspecified whether the command that turns tracing off is traced.

77194 77195 The default for all these options shall be off (unset) unless stated otherwise in the description of the option or unless the shell was invoked with them on; see *sh*.

77196 77197 77198 The remaining arguments shall be assigned in order to the positional parameters. The special parameter `'#'` shall be set to reflect the number of positional parameters. All positional parameters shall be unset before any new values are assigned.

77199 If the first argument is `'−'`, the results are unspecified.

77200 The special argument `"−−"` immediately following the *set* command name can be used to
77201 delimit the arguments if the first argument begins with `'+'` or `'−'`, or to prevent inadvertent
77202 listing of all shell variables when there are no arguments. The command *set* −− without *argument*
77203 shall unset all positional parameters and set the special parameter `'#'` to zero.

77204 **OPTIONS**

77205 See the DESCRIPTION.

77206 **OPERANDS**

77207 See the DESCRIPTION.

77208 **STDIN**

77209 Not used.

77210 **INPUT FILES**

77211 None.

77212 **ENVIRONMENT VARIABLES**

77213 None.

77214 **ASYNCHRONOUS EVENTS**

77215 Default.

77216 **STDOUT**

77217 See the DESCRIPTION.

77218 **STDERR**

77219 The standard error shall be used only for diagnostic messages.

77220 **OUTPUT FILES**

77221 None.

77222 **EXTENDED DESCRIPTION**

77223 None.

77224 **EXIT STATUS**

77225 0 Successful completion.

77226 >0 An invalid option was specified, or an error occurred.

77227 **CONSEQUENCES OF ERRORS**

77228 Default.

77229 **APPLICATION USAGE**

77230 Application writers should avoid relying on *set* −**e** within functions. For example, in the
77231 following script:

```
77232 set −e
77233 start() {
77234     some_server
77235     echo some_server started successfully
77236 }
77237 start || echo >&2 some_server failed
```

77238 the −**e** setting is ignored within the function body (because the function is a command in an
77239 AND-OR list other than the last). Therefore, if `some_server` fails, the function carries on to
77240 echo `"some_server started successfully"`, and the exit status of the function is zero
77241 (which means `"some_server failed"` is not output).

EXAMPLES

Write out all variables and their values:

```
set
```

Set $1, $2, and $3 and set "$#" to 3:

```
set c a b
```

Turn on the −**x** and −**v** options:

```
set -xv
```

Unset all positional parameters:

```
set --
```

Set $1 to the value of *x*, even if it begins with '−' or '+':

```
set -- "$x"
```

Set the positional parameters to the expansion of *x*, even if *x* expands with a leading '−' or '+':

```
set -- $x
```

RATIONALE

The *set* −− form is listed specifically in the SYNOPSIS even though this usage is implied by the Utility Syntax Guidelines. The explanation of this feature removes any ambiguity about whether the *set* −− form might be misinterpreted as being equivalent to *set* without any options or arguments. The functionality of this form has been adopted from the KornShell. In System V, *set* −− only unsets parameters if there is at least one argument; the only way to unset all parameters is to use *shift*. Using the KornShell version should not affect System V scripts because there should be no reason to issue it without arguments deliberately; if it were issued as, for example:

```
set -- "$@"
```

and there were in fact no arguments resulting from "$@", unsetting the parameters would have no result.

The *set* + form in early proposals was omitted as being an unnecessary duplication of *set* alone and not widespread historical practice.

The *noclobber* option was changed to allow *set* −**C** as well as the *set* −**o** *noclobber* option. The single-letter version was added so that the historical "$−" paradigm would not be broken; see Section 2.5.2.

The description of the −**e** option is intended to match the behavior of the 1988 version of the KornShell.

The −**h** flag is related to command name hashing. See *hash*.

The following *set* flags were omitted intentionally with the following rationale:

−**k** The −**k** flag was originally added by the author of the Bourne shell to make it easier for users of pre-release versions of the shell. In early versions of the Bourne shell the construct *set name=value* had to be used to assign values to shell variables. The problem with −**k** is that the behavior affects parsing, virtually precluding writing any compilers. To explain the behavior of −**k**, it is necessary to describe the parsing algorithm, which is implementation-defined. For example:

```
set -k; echo name=value
```

and:

```
set −k
echo name=value
```

behave differently. The interaction with functions is even more complex. What is more, the **−k** flag is never needed, since the command line could have been reordered.

−t The **−t** flag is hard to specify and almost never used. The only known use could be done with here-documents. Moreover, the behavior with *ksh* and *sh* differs. The reference page says that it exits after reading and executing one command. What is one command? If the input is *date;date*, *sh* executes both *date* commands while *ksh* does only the first.

Consideration was given to rewriting *set* to simplify its confusing syntax. A specific suggestion was that the *unset* utility should be used to unset options instead of using the non-*getopt*( )-able *+option* syntax. However, the conclusion was reached that the historical practice of using *+option* was satisfactory and that there was no compelling reason to modify such widespread historical practice.

The **−o** option was adopted from the KornShell to address user needs. In addition to its generally friendly interface, **−o** is needed to provide the *vi* command line editing mode, for which historical practice yields no single-letter option name. (Although it might have been possible to invent such a letter, it was recognized that other editing modes would be developed and **−o** provides ample name space for describing such extensions.)

Historical implementations are inconsistent in the format used for **−o** option status reporting. The **+o** format without an option-argument was added to allow portable access to the options that can be saved and then later restored using, for instance, a dot script.

Historically, *sh* did trace the command *set* **+x**, but *ksh* did not.

The *ignoreeof* setting prevents accidental logouts when the end-of-file character (typically <control>-D) is entered. A user shall explicitly *exit* to leave the interactive shell.

The *set* **−m** option was added to apply only to the UPE because it applies primarily to interactive use, not shell script applications.

The ability to do asynchronous notification became available in the 1988 version of the KornShell. To have it occur, the user had to issue the command:

```
trap "jobs −n" CLD
```

The C shell provides two different levels of an asynchronous notification capability. The environment variable *notify* is analogous to what is done in *set* **−b** or *set* **−o** *notify*. When set, it notifies the user immediately of background job completions. When unset, this capability is turned off.

The other notification ability comes through the built-in utility *notify*. The syntax is:

```
notify [%job ... ]
```

By issuing *notify* with no operands, it causes the C shell to notify the user asynchronously when the state of the current job changes. If given operands, *notify* asynchronously informs the user of changes in the states of the specified jobs.

To add asynchronous notification to the POSIX shell, neither the KornShell extensions to *trap*, nor the C shell *notify* environment variable seemed appropriate (*notify* is not a proper POSIX environment variable name).

The *set* **−b** option was selected as a compromise.

The *notify* built-in was considered to have more functionality than was required for simple

77326 asynchronous notification.

77327 Historically, some shells applied the **−u** option to all parameters including `$@` and `$*`. The
77328 standard developers felt that this was a misfeature since it is normal and common for `$@` and `$*`
77329 to be used in shell scripts regardless of whether they were passed any arguments. Treating these
77330 uses as an error when no arguments are passed reduces the value of **−u** for its intended purpose
77331 of finding spelling mistakes in variable names and uses of unset positional parameters.

77332 **FUTURE DIRECTIONS**

77333 None.

77334 **SEE ALSO**

77335 Section 2.14, *hash*

77336 XBD Section 4.23, Section 12.2

77337 **CHANGE HISTORY**

77338 **Issue 6**

77339 The obsolescent *set* command name followed by `'−'` has been removed.

77340 The following new requirements on POSIX implementations derive from alignment with the
77341 Single UNIX Specification:

77342 The *nolog* option is added to *set* **−o**.

77343 IEEE PASC Interpretation 1003.2 #167 is applied, clarifying that the options default also takes
77344 into account the description of the option.

77345 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
77346 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
77347 behavior is intended.

77348 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/8 is applied, changing the square
77349 brackets in the example in RATIONALE to be in bold, which is the typeface used for optional
77350 items.

77351 **Issue 7**

77352 Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first
77353 argument is `'−'`.

77354 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

77355 XSI shading is removed from the **−h** functionality.

77356 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0046 [52], XCU/TC1-2008/0047
77357 [155,280], XCU/TC1-2008/0048 [52], XCU/TC1-2008/0049 [52], and XCU/TC1-2008/0050
77358 [155,430] are applied.

77359 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0053 [584], XCU/TC2-2008/0054
77360 [717], XCU/TC2-2008/0055 [717], and XCU/TC2-2008/0056 [960] are applied.

77361 **NAME**

77362 shift ‡'shift positional parameters

77363 **SYNOPSIS**

77364 `shift [`*n*`]`

77365 **DESCRIPTION**

77366 The positional parameters shall be shifted. Positional parameter 1 shall be assigned the value of
77367 parameter (1+*n*), parameter 2 shall be assigned the value of parameter (2+*n*), and so on. The
77368 parameters represented by the numbers `"$#"` down to `"$#−n+1"` shall be unset, and the
77369 parameter `'#'` is updated to reflect the new number of positional parameters.

77370 The value *n* shall be an unsigned decimal integer less than or equal to the value of the special
77371 parameter `'#'`. If *n* is not given, it shall be assumed to be 1. If *n* is 0, the positional and special
77372 parameters are not changed.

77373 **OPTIONS**

77374 None.

77375 **OPERANDS**

77376 See the DESCRIPTION.

77377 **STDIN**

77378 Not used.

77379 **INPUT FILES**

77380 None.

77381 **ENVIRONMENT VARIABLES**

77382 None.

77383 **ASYNCHRONOUS EVENTS**

77384 Default.

77385 **STDOUT**

77386 Not used.

77387 **STDERR**

77388 The standard error shall be used only for diagnostic messages.

77389 **OUTPUT FILES**

77390 None.

77391 **EXTENDED DESCRIPTION**

77392 None.

77393 **EXIT STATUS**

77394 If the *n* operand is invalid or is greater than `"$#"`, this may be considered a syntax error and a
77395 non-interactive shell may exit; if the shell does not exit in this case, a non-zero exit status shall be
77396 returned. Otherwise, zero shall be returned.

77397 **CONSEQUENCES OF ERRORS**

77398 Default.

APPLICATION USAGE

None.

EXAMPLES

```
$ set a b c d e
$ shift 2
$ echo $*
c d e
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0051 [459] is applied.

77419 **NAME**

77420 times — write process times

77421 **SYNOPSIS**

77422 `times`

77423 **DESCRIPTION**

77424 The *times* utility shall write the accumulated user and system times for the shell and for all of its
77425 child processes, in the following POSIX locale format:

77426 `"%dm%fs %dm%fs\n%dm%fs %dm%fs\n", <shell user minutes>,`
77427 `<shell user seconds>, <shell system minutes>,`
77428 `<shell system seconds>, <children user minutes>,`
77429 `<children user seconds>, <children system minutes>,`
77430 `<children system seconds>`

77431 The four pairs of times shall correspond to the members of the **<sys/times.h> tms** structure
77432 (defined in XBD Chapter 13) as returned by *times*( ): *tms_utime*, *tms_stime*, *tms_cutime*, and
77433 *tms_cstime*, respectively.

77434 **OPTIONS**

77435 None.

77436 **OPERANDS**

77437 None.

77438 **STDIN**

77439 Not used.

77440 **INPUT FILES**

77441 None.

77442 **ENVIRONMENT VARIABLES**

77443 None.

77444 **ASYNCHRONOUS EVENTS**

77445 Default.

77446 **STDOUT**

77447 See the DESCRIPTION.

77448 **STDERR**

77449 The standard error shall be used only for diagnostic messages.

77450 **OUTPUT FILES**

77451 None.

77452 **EXTENDED DESCRIPTION**

77453 None.

77454 **EXIT STATUS**

77455 0 Successful completion.

77456 >0 An error occurred.

77457 **CONSEQUENCES OF ERRORS**

77458 Default.

APPLICATION USAGE

None.

EXAMPLES

```
$ times
0m0.43s 0m1.11s
8m44.18s 1m43.23s
```

RATIONALE

The *times* special built-in from the Single UNIX Specification is now required for all conforming shells.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/9 is applied, changing text in the DESCRIPTION from: ``Write the accumulated user and system times for the shell and for all of its child processes ...'' to: ``The *times* utility shall write the accumulated user and system times for the shell and for all of its child processes ...''.

Issue 7

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0056 [960] is applied.

77481 **NAME**

77482 trap ‡'trap signals

77483 **SYNOPSIS**

77484 `trap` *n* `[`*condition*`...]`

77485 `trap [`*action condition*`...]`

77486 **DESCRIPTION**

77487 If the first operand is an unsigned decimal integer, the shell shall treat all operands as
77488 conditions, and shall reset each condition to the default value. Otherwise, if there are operands,
77489 the first is treated as an action and the remaining as conditions.

77490 If *action* is `'-'`, the shell shall reset each *condition* to the default value. If *action* is null (`""`), the
77491 shell shall ignore each specified *condition* if it arises. Otherwise, the argument *action* shall be read
77492 and executed by the shell when one of the corresponding conditions arises. The action of *trap*
77493 shall override a previous action (either default action or one explicitly set). The value of `"$?"`
77494 after the *trap* action completes shall be the value it had before *trap* was invoked.

77495 The condition can be EXIT, 0 (equivalent to EXIT), or a signal specified using a symbolic name,
77496 without the SIG prefix, as listed in the tables of signal names in the **<signal.h>** header defined in
77497 XBD Chapter 13; for example, HUP, INT, QUIT, TERM. Implementations may permit names
77498 with the SIG prefix or ignore case in signal names as an extension. Setting a trap for SIGKILL or
77499 SIGSTOP produces undefined results.

77500 The environment in which the shell executes a *trap* on EXIT shall be identical to the environment
77501 immediately after the last command executed before the *trap* on EXIT was taken.

77502 Each time *trap* is invoked, the *action* argument shall be processed in a manner equivalent to:

77503 `eval` *action*

77504 Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although
77505 no error need be reported when attempting to do so. An interactive shell may reset or catch
77506 signals ignored on entry. Traps shall remain in place for a given shell until explicitly changed
77507 with another *trap* command.

77508 When a subshell is entered, traps that are not being ignored shall be set to the default actions,
77509 except in the case of a command substitution containing only a single *trap* command, when the
77510 traps need not be altered. Implementations may check for this case using only lexical analysis;
77511 for example, if `` `trap` `` and `$( trap -- )` do not alter the traps in the subshell, cases such as
77512 assigning `var=trap` and then using `$($var)` may still alter them. This does not imply that the
77513 *trap* command cannot be used within the subshell to set new traps.

77514 The *trap* command with no operands shall write to standard output a list of commands
77515 associated with each condition. If the command is executed in a subshell, the implementation
77516 does not perform the optional check described above for a command substitution containing
77517 only a single *trap* command, and no *trap* commands with operands have been executed since
77518 entry to the subshell, the list shall contain the commands that were associated with each
77519 condition immediately before the subshell environment was entered. Otherwise, the list shall
77520 contain the commands currently associated with each condition. The format shall be:

77521 `"trap -- %s %s ...\n", <`*action*`>, <`*condition*`> ...`

77522 The shell shall format the output, including the proper use of quoting, so that it is suitable for
77523 reinput to the shell as commands that achieve the same trapping results. For example:

```
77524 save_traps=$(trap)
77525 ...
77526 eval "$save_traps"
```

XSI XSI-conformant systems also allow numeric signal numbers for the conditions corresponding to the following signal names:

1 SIGHUP

2 SIGINT

3 SIGQUIT

6 SIGABRT

9 SIGKILL

14 SIGALRM

15 SIGTERM

The *trap* special built-in shall conform to XBD Section 12.2.

OPTIONS

None.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the DESCRIPTION.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

XSI If the trap name or number is invalid, a non-zero exit status shall be returned; otherwise, zero
XSI shall be returned. For both interactive and non-interactive shells, invalid signal names or numbers shall not be considered a syntax error and do not cause the shell to abort.

CONSEQUENCES OF ERRORS

Default.

77563 **APPLICATION USAGE**

77564 None.

77565 **EXAMPLES**

77566 Write out a list of all traps and actions:

77567 ```
trap
```

77568 Set a trap so the *logout* utility in the directory referred to by the *HOME* environment variable
77569 executes when the shell terminates:

77570 ```
trap '"$HOME"/logout' EXIT
```

77571 or:

77572 ```
trap '"$HOME"/logout' 0
```

77573 Unset traps on INT, QUIT, TERM, and EXIT:

77574 ```
trap - INT QUIT TERM EXIT
```

77575 **RATIONALE**

77576 Implementations may permit lowercase signal names as an extension. Implementations may
77577 also accept the names with the SIG prefix; no known historical shell does so. The *trap* and *kill*
77578 utilities in this volume of POSIX.1-2017 are now consistent in their omission of the SIG prefix for
77579 signal names. Some *kill* implementations do not allow the prefix, and *kill* **-l** lists the signals
77580 without prefixes.

77581 Trapping SIGKILL or SIGSTOP is syntactically accepted by some historical implementations, but
77582 it has no effect. Portable POSIX applications cannot attempt to trap these signals.

77583 The output format is not historical practice. Since the output of historical *trap* commands is not
77584 portable (because numeric signal values are not portable) and had to change to become so, an
77585 opportunity was taken to format the output in a way that a shell script could use to save and
77586 then later reuse a trap if it wanted.

77587 The KornShell uses an **ERR** trap that is triggered whenever *set* **-e** would cause an exit. This is
77588 allowable as an extension, but was not mandated, as other shells have not used it.

77589 The text about the environment for the EXIT trap invalidates the behavior of some historical
77590 versions of interactive shells which, for example, close the standard input before executing a
77591 trap on 0. For example, in some historical interactive shell sessions the following trap on 0
77592 would always print `"--"`:

77593 ```
trap 'read foo; echo "-$foo-"' 0
```

77594 The command:

77595 ```
trap 'eval " $cmd"' 0
```

77596 causes the contents of the shell variable *cmd* to be executed as a command when the shell exits.
77597 Using:

77598 ```
trap '$cmd' 0
```

77599 does not work correctly if *cmd* contains any special characters such as quoting or redirections.
77600 Using:

77601 ```
trap " $cmd" 0
```

77602 also works (the leading <space> character protects against unlikely cases where *cmd* is a decimal
77603 integer or begins with `'-'`), but it expands the *cmd* variable when the *trap* command is executed,

not when the exit action is executed.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

XSI-conforming implementations provide the mapping of signal names to numbers given above (previously this had been marked obsolescent). Other implementations need not provide this optional mapping.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #116 is applied.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0052 [53,268,440], XCU/TC1-2008/0053 [53,268,440], XCU/TC1-2008/0054 [163], XCU/TC1-2008/0055 [163], and XCU/TC1-2008/0056 [163] are applied.

77624 **NAME**

77625 unset ‡'unset values and attributes of variables and functions

77626 **SYNOPSIS**

77627 `unset [-fv] name...`

77628 **DESCRIPTION**

77629 Each variable or function specified by *name* shall be unset.

77630 If **-v** is specified, *name* refers to a variable name and the shell shall unset it and remove it from
77631 the environment. Read-only variables cannot be unset.

77632 If **-f** is specified, *name* refers to a function and the shell shall unset the function definition.

77633 If neither **-f** nor **-v** is specified, *name* refers to a variable; if a variable by that name does not
77634 exist, it is unspecified whether a function by that name, if any, shall be unset.

77635 Unsetting a variable or function that was not previously set shall not be considered an error and
77636 does not cause the shell to abort.

77637 The *unset* special built-in shall support XBD Section 12.2.

77638 Note that:

77639 `VARIABLE=`

77640 is not equivalent to an *unset* of **VARIABLE**; in the example, **VARIABLE** is set to `""`. Also, the
77641 variables that can be *unset* should not be misinterpreted to include the special parameters (see
77642 Section 2.5.2).

77643 **OPTIONS**

77644 See the DESCRIPTION.

77645 **OPERANDS**

77646 See the DESCRIPTION.

77647 **STDIN**

77648 Not used.

77649 **INPUT FILES**

77650 None.

77651 **ENVIRONMENT VARIABLES**

77652 None.

77653 **ASYNCHRONOUS EVENTS**

77654 Default.

77655 **STDOUT**

77656 Not used.

77657 **STDERR**

77658 The standard error shall be used only for diagnostic messages.

77659 **OUTPUT FILES**

77660 None.

77661 **EXTENDED DESCRIPTION**

77662 None.

77663 **EXIT STATUS**

77664 0 All *name* operands were successfully unset.

77665 >0 At least one *name* could not be unset.

77666 **CONSEQUENCES OF ERRORS**

77667 Default.

77668 **APPLICATION USAGE**

77669 None.

77670 **EXAMPLES**

77671 Unset *VISUAL* variable:

77672 ```
unset -v VISUAL
```

77673 Unset the functions **foo** and **bar**:

77674 ```
unset -f foo bar
```

77675 **RATIONALE**

77676 Consideration was given to omitting the **-f** option in favor of an *unfunction* utility, but the
77677 standard developers decided to retain historical practice.

77678 The **-v** option was introduced because System V historically used one name space for both
77679 variables and functions. When *unset* is used without options, System V historically unset either a
77680 function or a variable, and there was no confusion about which one was intended. A portable
77681 POSIX application can use *unset* without an option to unset a variable, but not a function; the **-f**
77682 option must be used.

77683 **FUTURE DIRECTIONS**

77684 None.

77685 **SEE ALSO**

77686 Section 2.14

77688 **CHANGE HISTORY**

77689 **Issue 6**

77690 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
77691 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
77692 behavior is intended.

77693 **Issue 7**

77694 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Chapter 3

Batch Environment Services

OB BE This chapter describes the services and utilities that shall be implemented on all systems that claim conformance to the Batch Environment Services and Utilities option. The functionality described in this section shall be provided on implementations that support the Batch Environment Services and Utilities option (and the rest of this section is not further shaded for this option).

Note that the Batch Environment Services and Utilities option is marked obsolescent in Issue 7.

3.1 General Concepts

3.1.1 Batch Client-Server Interaction

Batch jobs are created and managed by batch servers. A batch client interacts with a batch server to access batch services on behalf of the user. In order to use batch services, a user must have access to a batch client.

A batch server is a computational entity, such as a daemon process, that provides batch services. Batch servers route, queue, modify, and execute batch jobs on behalf of batch clients.

The batch utilities described in this volume of POSIX.1-2017 (and listed in Table 3-1) are clients of batch services; they allow users to perform actions on the job such as creating, modifying, and deleting batch jobs from a shell command line. Although these batch utilities may be said to accomplish certain services, they actually obtain services on behalf of a user by means of requests to batch servers.

Table 3-1 Batch Utilities

qalter	*qmove*	*qrls*	*qstat*
qdel	*qmsg*	*qselect*	*qsub*
qhold	*qrerun*	*qsig*	

Client-server interaction takes place by means of the batch requests defined in this chapter. Because direct access to batch jobs and queues is limited to batch servers, clients and servers of different implementations can interoperate, since dependencies on private structures for batch jobs and queues are limited to batch servers. Also, batch servers may be clients of other batch servers.

3.1.2 Batch Queues

Two types of batch queue are described: routing queues and execution queues. When a batch job is placed in a routing queue, it is a candidate for routing. A batch job is removed from routing queues under the following conditions:

The batch job has been routed to another queue.

The batch job has been deleted from the batch queue.

The batch job has been aborted.

When a batch job is placed in an execution queue, it is a candidate for execution.

A batch job is removed from an execution queue under the following conditions:

The batch job has been executed and exited.

The batch job has been aborted.

The batch job has been deleted from the batch queue.

The batch job has been moved to another queue.

Access to a batch queue is limited to the batch server that manages the batch queue. Clients never access a batch queue or a batch job directly, either to read or write information; all client access to batch queues or jobs takes place through batch servers.

3.1.3 Batch Job Creation

When a batch server creates a batch job on behalf of a client, it shall assign a batch job identifier to the job. A batch job identifier consists of both a sequence number that is unique among the sequence numbers issued by that server and the name of the server. Since the batch server name is unique within a name space, the job identifier is likewise unique within the name space.

The batch server that creates a batch job shall return the batch server-assigned job identifier to the client that requested the job creation. If the batch server routes or moves the job to another server, it sends the job identifier with the job. Once assigned, the job identifier of a batch job shall never change.

3.1.4 Batch Job Tracking

Since a batch job may be moved after creation, the batch server name component of the job identifier need not indicate the location of the job. An implementation may provide a batch job tracking mechanism, in which case the user generally does not need to know the location of the job. However, an implementation need not provide a batch job tracking mechanism, in which case the user must find routed jobs by probing the possible destinations.

3.1.5 Batch Job Routing

To route a batch job, a batch server either moves the job to some other queue that is managed by the batch server, or requests that some other batch server accept the job.

Each routing queue has one or more queues to which it can route batch jobs. The batch server administrator creates routing queues.

A batch server may route a batch job from a routing queue to another routing queue. Batch servers shall prevent or otherwise handle cases of circular routing paths. As a deferred service, a batch server routes jobs from the routing queues that it manages. The algorithm by which a batch server selects a batch queue to which to route a batch job is implementation-defined.

A batch job need not be eligible for routing to all the batch queues fed by the routing queue from which it is routed. A batch server that has been asked to accept the job may reject the request if the job requires resources that are unavailable to that batch server, or if the client is not authorized to access the batch server.

Batch servers may route high-priority jobs before low-priority jobs, but, on other than overloaded systems, the effect may be imperceptible to the user. If all the batch servers fed by a routing queue reject requests to accept the job for reasons that are permanent, the batch server that manages the job shall abort the job. If all or some rejections are temporary, the batch server should try to route the job again at some later point.

The reasons for rejecting a batch job are implementation-defined.

The reasons for which the routing should be retried later and the reasons for which the job should be aborted are also implementation-defined.

3.1.6 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path* attribute of the job. The script shall be passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state. The primary program that is executed by a batch job is typically, though not necessarily, a shell program.

A batch server shall execute eligible jobs as a deferred service—no client request is necessary once the batch job is created and eligible. However, the attributes of a batch job, such as the job hold type, may render the job ineligible. A batch server shall scan the execution queues that it manages for jobs that are eligible for execution. The algorithm by which the batch server selects eligible jobs for execution is implementation-defined.

As part of creating the process for the batch job, the batch server shall open the standard output and standard error streams of the session.

The attributes of a batch job may indicate that the batch server executing the job shall send mail to a list of users at the time it begins execution of the job.

3.1.7 Batch Job Exit

When the session leader of an executing job terminates, the job exits. As part of exiting a batch job, the batch server that manages the job shall remove the job from the batch queue in which it resides. The server shall transfer output files of the job to a location described by the attributes of the job.

The attributes of a batch job may indicate that the batch server managing the job shall send mail to a list of users at the time the job exits.

3.1.8 Batch Job Abort

A batch server shall abort jobs for which a required deferred service cannot be performed. The attributes of a batch job may indicate that the batch server that aborts the job shall send mail to a list of users at the time it aborts the job.

3.1.9 Batch Authorization

Clients, such as the batch environment utilities (marked BE), access batch services by means of requests to one or more batch servers. To acquire the services of any given batch server, the user identifier under which the client runs must be authorized to use that batch server.

The user with an associated user name that creates a batch job shall own the job and can perform actions such as read, modify, delete, and move.

A user identifier of the same value at a different host need not be the same user. For example, user name *smith* at host **alpha** may or may not represent the same person as user name *smith* at host **beta**. Likewise, the same person may have access to different user names on different hosts.

An implementation may optionally provide an authorization mechanism that permits one user name to access jobs under another user name.

A process on a client host may be authorized to run processes under multiple user names at a batch server host. Where appropriate, the utilities defined in this volume of POSIX.1-2017 provide a means for a user to choose from among such user names when creating or modifying a batch job.

3.1.10 Batch Administration

The processing of a batch job by a batch server is affected by the attributes of the job. The processing of a batch job may also be affected by the attributes of the batch queue in which the job resides and by the status of the batch server that manages the job. See also XBD Chapter 3 (on page 33) for batch definitions.

3.1.11 Batch Notification

Whereas batch servers are persistent entities, clients are often transient. For example, the *qsub* utility creates a batch job and exits. For this reason, batch servers notify users of batch job events by sending mail to the user that owns the job, or to other designated users.

3.2 Batch Services

The presence of Batch Environment Services and Utilities option services is indicated by the configuration variable POSIX2_PBS. A conforming batch server provides services as defined in this section.

A batch server shall provide batch services in two ways:

1. The batch server provides a service at the request of a client.
2. The batch server provides a deferred service as a result of a change in conditions monitored by the batch server.

If a batch server cannot complete a request, it shall reject the request. If a batch server cannot complete a deferred service for a batch job, the batch server shall abort the batch job. Table 3-2 is a summary of environment variables that shall be supported by an implementation of the batch server and utilities.

Table 3-2 Environment Variable Summary

Variable	Description
PBS_DPREFIX	Defines the directive prefix (see *qsub*)
PBS_ENVIRONMENT	Batch Job is batch or interactive (see Section 3.2.2.1)
PBS_JOBID	The *job_identifier* attribute of job (see Section 3.2.3.8)
PBS_JOBNAME	The *job_name* attribute of job (see Section 3.2.3.8)
PBS_O_HOME	Defines the *HOME* of the batch client (see *qsub*)
PBS_O_HOST	Defines the host name of the batch client (see *qsub*)
PBS_O_LANG	Defines the *LANG* of the batch client (see *qsub*)
PBS_O_LOGNAME	Defines the *LOGNAME* of the batch client (see *qsub*)
PBS_O_MAIL	Defines the *MAIL* of the batch client (see *qsub*)
PBS_O_PATH	Defines the *PATH* of the batch client (see *qsub*)
PBS_O_QUEUE	Defines the submit queue of the batch client (see *qsub*)
PBS_O_SHELL	Defines the *SHELL* of the batch client (see *qsub*)
PBS_O_TZ	Defines the *TZ* of the batch client (see *qsub*)
PBS_O_WORKDIR	Defines the working directory of the batch client (see *qsub*)
PBS_QUEUE	Defines the initial execution queue (see Section 3.2.2.1)

3.2.1 Batch Job States

A batch job shall always be in one of the following states: QUEUED, RUNNING, HELD, WAITING, EXITING, or TRANSITING. The state of a batch job determines the types of requests that the batch server that manages the batch job can accept for the batch job. A batch server shall change the state of a batch job either in response to service requests from clients or as a result of deferred services, such as job execution or job routing.

A batch job that is in the QUEUED state resides in a queue but is still pending either execution or routing, depending on the queue type.

A batch server that queues a batch job in a routing queue shall put the batch job in the QUEUED state. A batch server that puts a batch job in an execution queue, but has not yet executed the batch job, shall put the batch job in the QUEUED state. A batch job that resides in an execution queue and is executing is defined to be in the RUNNING state. While a batch job is in the RUNNING state, a session leader is associated with the batch job.

A batch job that resides in an execution queue, but is ineligible to run because of a hold attribute, is defined to be in the HELD state.

A batch job that is not held, but must wait until a future date and time before executing, is defined to be in the WAITING state.

When the session leader associated with a running job exits, the batch job shall be placed in the EXITING state.

A batch job for which the session leader has terminated is defined to be in the EXITING state, and the batch server that manages such a batch job cannot accept job modification requests that affect the batch job. While a batch job is in the EXITING state, the batch server that manages the batch job is staging output files and notifying clients of job completion. Once a batch job has exited, it no longer exists as an object managed by a batch server.

A batch job that is being moved from a routing queue to another queue is defined to be in the TRANSITING state.

When a batch job in a routing queue has been selected to be moved to a new destination, then the batch job shall be in either the QUEUED state or the TRANSITING state, depending on the batch server implementation.

Batch jobs with either an *Execution_Time* attribute value set in the future or a *Hold_Types* attribute of value not equal to NO_HOLD, or both, may be routed or held in the routing queue. The treatment of jobs with the *Execution_Time* or *Hold_Types* attributes in a routing queue is implementation-defined.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has a *Hold_Types* attribute value of other than NO_HOLD, then the job should be in the HELD state.

Note: The effect of a hold upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

A *Hold_Types* attribute value of NO_HOLD

An *Execution_Time* attribute in the past

then the batch job shall be in the QUEUED state.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

A *Hold_Types* attribute value of NO_HOLD

An *Execution_Time* attribute in the future

then the batch job may be in the WAITING state.

Note: The effect of a future execution time upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

Table 3-3 describes the next state of a batch job, given the current state of the batch job and the type of request. Table 3-4 (on page 2435) describes the response of a batch server to a request, given the current state of the batch job and the type of request.

3.2.2 Deferred Batch Services

This section describes the deferred services performed by batch servers: job execution, job routing, job exit, job abort, and the rerunning of jobs after a restart.

3.2.2.1 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path_List* attribute of the batch job. The script is passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state.

Table 3-3 Next State Table

Request Type	Current State						
	X	**Q**	**R**	**H**	**W**	**E**	**T**
Queue Batch Job Request	Q	e	e	e	e	e	e
Modify Batch Job Request	e	Q	R	H	W	e	T
Delete Batch Job Request	e	X	E	X	X	E	X

77943 W WAITING

77944 E EXITING

77945 T TRANSITING

77946 e Error

77947 A batch server that has an execution queue containing jobs is said to own the queue and manage
77948 the batch jobs in that queue. A batch server that has been started shall execute the batch jobs in
77949 the execution queues owned by the batch server. The batch server shall schedule for execution
77950 those jobs in the execution queues that are in the QUEUED state. The algorithm for scheduling
77951 jobs is implementation-defined.

77952 A batch server that executes a batch job shall create, in the environment of the session leader of
77953 the batch job, an environment variable named *PBS_ENVIRONMENT*, the value of which is the
77954 string PBS_BATCH encoded in the portable character set.

77955 A batch server that executes a batch job shall create, in the environment of the session leader of
77956 the batch job, an environment variable named *PBS_QUEUE*, the value of which is the name of
77957 the execution queue of the batch job encoded in the portable character set.

77958 To rerun a batch job is to requeue a batch job that is currently executing and then kill the session
77959 leader of the executing job by sending a SIGKILL prior to completion; see Section 3.2.3.11 (on
77960 page 2447). A batch server that reruns a batch job shall append the standard output and
77961 standard error files of the batch job to the corresponding files of the previous execution, if they
77962 exist, with appropriate annotation. If either file does not exist, that file shall be created as in
77963 normal execution.

77983 O OK

77984 e Error message

77985 77986 The execution of a batch job by a batch server shall be controlled by job, queue, and server attributes, as defined in this section.

77987 **Account_Name Attribute**

77988 77989 77990 Batch accounting is an optional feature of batch servers. If a batch server implements accounting, the statements in this section apply and the configuration variable POSIX2_PBS_ACCOUNTING shall be set to 1.

77991 77992 A batch server that executes a batch job shall charge the account named in the *Account_Name* attribute of the batch job for resources consumed by the batch job.

77993 77994 If the *Account_Name* attribute of the batch job is absent from the batch job attribute list or is altered while the batch job is in execution, the batch server action is implementation-defined.

77995 **Checkpoint Attribute**

77996 77997 77998 Batch checkpointing is an optional feature of batch servers. If a batch server implements checkpointing, the statements in this section apply and the configuration variable POSIX2_PBS_CHECKPOINT shall be set to 1.

77999 78000 78001 78002 78003 There are two attributes associated with the checkpointing feature: *Checkpoint* and *Minimum_Cpu_Interval*. *Checkpoint* is a batch job attribute, while *Minimum_Cpu_Interval* is a queue attribute. An implementation that does not support checkpointing shall support the *Checkpoint* job attribute to the extent that the batch server shall maintain and pass this attribute to other servers.

78004 78005 78006 The behavior of a batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_UNSPECIFIED is implementation-defined. A batch server that executes a batch job for which the value of the *Checkpoint* attribute is NO_CHECKPOINT shall

not checkpoint the batch job.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_SHUTDOWN shall checkpoint the batch job only when the batch server accepts a request to shut down during the time when the batch job is in the RUNNING state.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_MIN_CPU_INTERVAL shall checkpoint the batch job at the interval specified by the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected. The *Minimum_Cpu_Interval* attribute shall be specified in units of CPU minutes.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is an unsigned integer shall checkpoint the batch job at an interval that is the value of either the *Checkpoint* attribute, or the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected, whichever is greater. Both intervals shall be in units of CPU minutes. When the *Minimum_Cpu_Interval* attribute is greater than the *Checkpoint* attribute, the batch job shall write a warning message to the standard error stream of the batch job.

Error_Path Attribute

The *Error_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*. When the *Join_Path* attribute of the batch job is set to the value FALSE and the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_ERROR, a batch server that executes a batch job shall perform one of the following actions:

Set the standard error stream of the session leader of the batch job to the path described by the value of the *Error_Path* attribute of the batch job.

Buffer the standard error of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the *Error_Path* attribute of the batch job.

Applications shall not rely on having access to the standard error of a batch job prior to the completion of the batch job.

When the *Error_Path* attribute does not specify a host name, then the batch server shall retain the standard error of the batch job on the host of execution.

When the *Error_Path* attribute does specify a host name and the *Keep_Files* attribute does not contain the value KEEP_STD_ERROR, then the final destination of the standard error of the batch job shall be on the host whose host name is specified.

If the path indicated by the value of the *Error_Path* attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.

When the batch server buffers the standard error of the batch job and the file cannot be opened for write upon completion of the batch job, then the server shall place the standard error in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the *mailx* utility.

If a batch server that does not buffer the standard error cannot open the standard error path of the batch job for write access, then the batch server shall abort the batch job.

78047 **Execution_Time Attribute**

78048 A batch server shall not execute a batch job before the time represented by the value of the
78049 *Execution_Time* attribute of the batch job. The *Execution_Time* attribute is defined in seconds since
78050 the Epoch.

78051 **Hold_Types Attribute**

78052 A batch server shall support the following hold types:

78053 `s` Can be set or released by a user with at least a privilege level of batch administrator
78054 (SYSTEM).

78055 `o` Can be set or released by a user with at least a privilege level of batch operator
78056 (OPERATOR).

78057 `u` Can be set or released by the user with at least a privilege level of user, where the user is
78058 defined in the *Job_Owner* attribute (USER).

78059 `n` Indicates that none of the *Hold_Types* attributes are set (NO_HOLD).

78060 An implementation may define other hold types. Any additional hold types, how they are
78061 specified, their internal representation, their behavior, and how they affect the behavior of other
78062 utilities are implementation-defined.

78063 The value of the *Hold_Types* attribute shall be the union of the valid hold types (`'s'`, `'o'`, `'u'`,
78064 and any implementation-defined hold types), or `'n'`.

78065 A batch server shall not execute a batch job if the *Hold_Types* attribute of the batch job has a
78066 value other than NO_HOLD. If the *Hold_Types* attribute of the batch job has a value other than
78067 NO_HOLD, the batch job shall be in the HELD state.

78068 **Job_Owner Attribute**

78069 The *Job_Owner* attribute consists of a pair of user name and host name values of the form:

78070 `username@hostname`

78071 A batch server that accepts a *Queue Batch Job Request* shall set the *Job_Owner* attribute to a string
78072 that is the *username@hostname* of the user who submitted the job.

78073 **Join_Path Attribute**

78074 A batch server that executes a batch job for which the value of the *Join_Path* attribute is TRUE
78075 shall ignore the value of the *Error_Path* attribute and merge the standard error of the batch job
78076 with the standard output of the batch job.

78077 **Keep_Files Attribute**

78078 A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes
78079 the value KEEP_STD_OUTPUT shall retain the standard output of the batch job on the host
78080 where execution occurs. The standard output shall be retained in the home directory of the user
78081 under whose user ID the batch job is executed and the filename shall be the default filename for
78082 the standard output as defined under the **−o** option of the *qsub* utility. The *Output_Path* attribute
78083 is not modified.

78084 A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes
78085 the value KEEP_STD_ERROR shall retain the standard error of the batch job on the host where
78086 execution occurs. The standard error shall be retained in the home directory of the user under
78087 whose user ID the batch job is executed and the filename shall be the default filename for

78088 standard error as defined under the **−e** option of the *qsub* utility. The *Error_Path* attribute is not
78089 modified.

78090 A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes
78091 values other than KEEP_STD_OUTPUT and KEEP_STD_ERROR shall retain these other files on
78092 the host where execution occurs. These files (with implementation-defined names) shall be
78093 retained in the home directory of the user under whose user identifier the batch job is executed.

78094 **Mail_Points and Mail_Users Attributes**

78095 A batch server that executes a batch job for which one of the values of the *Mail_Points* attribute is
78096 the value MAIL_AT_BEGINNING shall send a mail message to each user account listed in the
78097 *Mail_Users* attribute of the batch job.

78098 The mail message shall contain at least the batch job identifier, queue, and server at which the
78099 batch job currently resides, and the *Job_Owner* attribute.

78100 **Output_Path Attribute**

78101 The *Output_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*.
78102 When the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_OUTPUT, a
78103 batch server that executes a batch job shall either:

78104 Set the standard output stream of the session leader of the batch job to the destination
78105 described by the value of the *Output_Path* attribute of the batch job.

78106 or:

78107 Buffer the standard output of the session leader of the batch job until completion of the
78108 batch job, and when the batch job exits return the contents to the destination described by
78109 the value of the *Output_Path* attribute of the batch job.

78110 When the *Output_Path* attribute does not specify a host name, then the batch server shall retain
78111 the standard output of the batch job on the host of execution.

78112 When the *Keep_Files* attribute does not contain the value KEEP_STD_OUTPUT and the
78113 *Output_Path* attribute does specify a host name, then the final destination of the standard output
78114 of the batch job shall be on the host specified.

78115 If the path specified in the *Output_Path* attribute of the batch job is a relative path, the batch
78116 server shall expand the path relative to the home directory of the user on the host to which the
78117 file is being returned.

78118 Whether or not the batch server buffers the standard output of the batch job until completion of
78119 the batch job is implementation-defined. Applications shall not rely on having access to the
78120 standard output of a batch job prior to the completion of the batch job.

78121 When the batch server does buffer the standard output of the batch job and the file cannot be
78122 opened for write upon completion of the batch job, then the batch server shall place the standard
78123 output in an implementation-defined location and notify the user of the location via mail. It shall
78124 be possible for the user to process this mail using the *mailx* utility.

78125 If a batch server that does not buffer the standard output cannot open the standard output path
78126 of the batch job for write access, then the batch server shall abort the batch job.

78127 **Priority Attribute**

78128 A batch server implementation may choose to preferentially execute a batch job based on the
78129 *Priority* attribute. The interpretation of the batch job *Priority* attribute by a batch server is
78130 implementation-defined. If an implementation uses the *Priority* attribute, it shall interpret larger
78131 values of the *Priority* attribute to mean the batch job shall be preferentially selected for execution.

78132 **Rerunable Attribute**

78133 A batch job that began execution but did not complete, because the batch server either shut
78134 down or terminated abnormally, shall be requeued if the *Rerunable* attribute of the batch job has
78135 the value TRUE.

78136 If a batch job, which was requeued after beginning execution but prior to completion, has a valid
78137 checkpoint file and the batch server supports checkpointing, then the batch job shall be restarted
78138 from the last valid checkpoint.

78139 If the batch job cannot be restarted from a checkpoint, then when a batch job has a *Rerunable*
78140 attribute value of TRUE and was requeued after beginning execution but prior to completion,
78141 the batch server shall place the batch job into execution at the beginning of the job.

78142 When a batch job has a *Rerunable* attribute value other than TRUE and was requeued after
78143 beginning execution but prior to completion, and the batch job cannot be restarted from a
78144 checkpoint, then the batch server shall abort the batch job.

78145 **Resource_List Attribute**

78146 A batch server that executes a batch job shall establish the resource limits of the session leader of
78147 the batch job according to the values of the *Resource_List* attribute of the batch job. Resource
78148 limits shall be enforced by an implementation-defined method.

78149 **Shell_Path_List Attribute**

78150 The *Shell_Path_List* job attribute consists of a list of pairs of pathname and host name values. The
78151 host name component can be omitted, in which case the pathname serves as the default
78152 pathname when a batch server cannot find the name of the host on which it is running in the list.

78153 A batch server that executes a batch job shall select, from the value of the *Shell_Path_List*
78154 attribute of the batch job, a pathname where the shell to execute the batch job shall be found.
78155 The batch server shall select the pathname, in order of preference, according to the following
78156 methods:

78157 Select the pathname that contains the name of the host on which the batch server is
78158 running.

78159 Select the pathname for which the host name has been omitted.

78160 Select the pathname for the login shell of the user under which the batch job is to execute.

78161 If the shell path value selected is an invalid pathname, the batch server shall abort the batch job.

78162 If the value of the selected pathname from the *Shell_Path_List* attribute of the batch job
78163 represents a partial path, the batch server shall expand the path relative to a path that is
78164 implementation-defined.

78165 The batch server that executes the batch job shall execute the program that was selected from the
78166 *Shell_Path_List* attribute of the batch job. The batch server shall pass the path to the script of the
78167 batch job as the first argument to the shell program.

78168 **User_List Attribute**

78169 The *User_List* job attribute consists of a list of pairs of user name and host name values. The host
78170 name component can be omitted, in which case the user name serves as a default when a batch
78171 server cannot find the name of the host on which it is running in the list.

78172 A batch server that executes a batch job shall select, from the value of the *User_List* attribute of
78173 the batch job, a user name under which to create the session leader. The server shall select the
78174 user name, in order of preference, according to the following methods:

78175 Select the user name of a value that contains the name of the host on which the batch
78176 server executes.

78177 Select the user name of a value for which the host name has been omitted.

78178 Select the user name from the *Job_Owner* attribute of the batch job.

78179 **Variable_List Attribute**

78180 A batch server that executes a batch job shall create, in the environment of the session leader of
78181 the batch job, each environment variable listed in the *Variable_List* attribute of the batch job, and
78182 set the value of each such environment variable to that of the corresponding variable in the
78183 variable list.

78184 *3.2.2.2 Batch Job Routing*

78185 To route a batch job is to select a queue from a list and move the batch job to that queue.

78186 A batch server that has routing queues, which have been started, shall route the jobs in the
78187 routing queues owned by the batch server. A batch server may delay the routing of a batch job.
78188 The algorithm for selecting a batch job and the queue to which it will be routed is
78189 implementation-defined.

78190 When a routing queue has multiple possible destinations specified, then the precedence of the
78191 destinations is implementation-defined.

78192 A batch server that routes a batch job to a queue at another server shall move the batch job into
78193 the target queue with a *Queue Batch Job Request*.

78194 If the target server rejects the *Queue Batch Job Request*, the routing server shall retry routing the
78195 batch job or abort the batch job. A batch server that retries failed routings shall provide a means
78196 for the batch administrator to specify the number of retries and the minimum period of time
78197 between retries. The means by which an administrator specifies the number of retries and the
78198 delay between retries is implementation-defined. When the number of retries specified by the
78199 batch administrator has been exhausted, the batch server shall abort the batch job and perform
78200 the functions of *Batch Job Exit*; see Section 3.2.2.3.

78201 *3.2.2.3 Batch Job Exit*

78202 For each job in the EXITING state, the batch server that exited the batch job shall perform the
78203 following deferred services in the order specified:

78204 1. If buffering standard error, move that file into the location specified by the *Error_Path*
78205 attribute of the batch job.

78206 2. If buffering standard output, move that file into the location specified by the *Output_Path*
78207 attribute of the batch job.

3. If the *Mail_Points* attribute of the batch job includes MAIL_AT_EXIT, send mail to the users listed in the *Mail_Users* attribute of the batch job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, and the *Job_Owner* attribute.
4. Remove the batch job from the queue.

If a batch server that buffers the standard error output cannot return the standard error file to the standard error path at the time the batch job exits, the batch server shall do one of the following:

Mail the standard error file to the batch job owner.

Save the standard error file and mail the location and name of the file where the standard error is stored to the batch job owner.

Save the standard error file and notify the user by other implementation-defined means.

If a batch server that buffers the standard output cannot return the standard output file to the standard output path at the time the batch job exits, the batch server shall do one of the following:

Mail the standard output file to the batch job owner.

Save the standard output file and mail the location and name of the file where the standard output is stored to the batch job owner.

Save the standard output file and notify the user by other implementation-defined means.

At the conclusion of job exit processing, the batch job is no longer managed by a batch server.

3.2.2.4 *Batch Server Restart*

A batch server that has been either shutdown or terminated abnormally, and has returned to operation, is said to have ``restarted''.

Upon restarting, a batch server shall requeue those jobs managed by the batch server that were in the RUNNING state at the time the batch server shut down and for which the *Rerunable* attribute of the batch job has the value TRUE.

Queues are defined to be non-volatile. A batch server shall store the content of queues that it controls in such a way that server and system shutdowns do not erase the content of the queues.

3.2.2.5 *Batch Job Abort*

A batch server that cannot perform a deferred service for a batch job shall abort the batch job.

A batch server that aborts a batch job shall perform the following services:

Delete the batch job from the queue in which it resides.

If the *Mail_Points* attribute of the batch job includes the value MAIL_AT_ABORT, send mail to the users listed in the value of the *Mail_Users* attribute of the job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, the *Job_Owner* attribute, and the reason for the abort.

If the batch job was in the RUNNING state, terminate the session leader of the executing job by sending the session leader a SIGKILL, place the batch job in the EXITING state, and perform the actions of *Batch Job Exit*.

3.2.3 Requested Batch Services

This section describes the services provided by batch servers in response to requests from clients. Table 3-5 summarizes the current set of batch service requests and for each gives its type (deferred or not) and whether it is an optional function.

Table 3-5 Batch Services Summary

Batch Service	Deferred	Optional
Batch Job Execution	Yes	No
Batch Job Routing	Yes	No
Batch Job Exit	Yes	No
Batch Server Restart	Yes	No
Batch Job Abort	Yes	No
Delete Batch Job Request	No	No
Hold Batch Job Request	No	No
Batch Job Message Request	No	Yes
Batch Job Status Request	No	No
Locate Batch Job Request	No	Yes
Modify Batch Job Request	No	No
Move Batch Job Request	No	No
Queue Batch Job Request	No	No
Batch Queue Status Request	No	No
Release Batch Job Request	No	No
Rerun Batch Job Request	No	No
Select Batch Jobs Request	No	No
Server Shutdown Request	No	No
Server Status Request	No	No
Signal Batch Job Request	No	No
Track Batch Job Request	No	Yes

If a request is rejected because the batch client is not authorized to perform the action, the batch server shall return the same status as when the batch job does not exist.

3.2.3.1 *Delete Batch Job Request*

A batch job is defined to have been deleted when it has been removed from the queue in which it resides and not instantiated in another queue. A client requests that the server that manages a batch job delete the batch job. Such a request is called a *Delete Batch Job Request*.

A batch server shall reject a *Delete Batch Job Request* if any of the following statements are true:

The user of the batch client is not authorized to delete the designated job.

The designated job is not managed by the batch server.

The designated job is in a state inconsistent with the delete request.

A batch server may reject a *Delete Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server requested to delete a batch job shall delete the batch job if the batch job exists and is not in the EXITING state.

A batch server that deletes a batch job in the RUNNING state shall send a SIGKILL signal to the

session leader of the batch job. It is implementation-defined whether additional signals are sent to the session leader of the job prior to sending the SIGKILL signal.

A batch server that deletes a batch job in the RUNNING state shall place the batch job in the EXITING state after it has killed the session leader of the batch job and shall perform the actions of *Batch Job Exit*.

3.2.3.2 *Hold Batch Job Request*

A batch client can request that the batch server add one or more holds to a batch job. Such a request is called a *Hold Batch Job Request*.

A batch server shall reject a *Hold Batch Job Request* if any of the following statements are true:

The batch server does not support one or more of the requested holds to be added to the batch job.

The user of the batch client is not authorized to add one or more of the requested holds to the batch job.

The batch server does not manage the specified job.

The designated job is in the EXITING state.

A batch server may reject a *Hold Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Hold Batch Job Request* for a batch job in the RUNNING state shall place a hold on the batch job. The effects, if any, the hold will have on a batch job in the RUNNING state are implementation-defined.

A batch server that accepts a *Hold Batch Job Request* shall add each type of hold listed in the *Hold Batch Job Request*, that is not already present, to the value of the *Hold_Types* attribute of the batch job.

3.2.3.3 *Batch Job Message Request*

Batch Job Message Request is an optional feature of batch servers. If an implementation supports *Batch Job Message Request*, the statements in this section apply and the configuration variable POSIX2_PBS_MESSAGE shall be set to 1.

A batch client can request that a batch server write a message into certain output files of a batch job. Such a request is called a *Batch Job Message Request*.

A batch server shall reject a *Batch Job Message Request* if any of the following statements are true:

The batch server does not support sending messages to jobs.

The user of the batch client is not authorized to post a message to the designated job.

The designated job does not exist on the batch server.

The designated job is not in the RUNNING state.

A batch server may reject a *Batch Job Message Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Batch Job Message Request* shall write the message sent by the batch client into the files indicated by the batch client.

78330 *3.2.3.4 Batch Job Status Request*

78331 A batch client can request that a batch server respond with the status and attributes of a batch
78332 job. Such a request is called a *Batch Job Status Request*.

78333 A batch server shall reject a *Batch Job Status Request* if any of the following statements are true:

78334 The user of the batch client is not authorized to query the status of the designated job.

78335 The designated job is not managed by the batch server.

78336 A batch server may reject a *Batch Job Status Request* for other implementation-defined reasons.
78337 The method used to determine whether the user of a client is authorized to perform the
78338 requested action is implementation-defined.

78339 A batch server that accepts a *Batch Job Status Request* shall return a *Batch Job Status Message* to the
78340 batch client.

78341 A batch server may return other information in response to a *Batch Job Status Request*.

78342 *3.2.3.5 Locate Batch Job Request*

78343 *Locate Batch Job Request* is an optional feature of batch servers. If an implementation supports
78344 *Locate Batch Job Request*, the statements in this section apply and the configuration variable
78345 POSIX2_PBS_LOCATE shall be set to 1.

78346 A batch client can ask a batch server to respond with the location of a batch job that was created
78347 by the batch server. Such a request is called a *Locate Batch Job Request*.

78348 A batch server that accepts a *Locate Batch Job Request* shall return a *Batch Job Location Message* to
78349 the batch client.

78350 A batch server may reject a *Locate Batch Job Request* for a batch job that was not created by that
78351 server.

78352 A batch server may reject a *Locate Batch Job Request* for a batch job that is no longer managed by
78353 that server; that is, for a batch job that is not in a queue owned by that server.

78354 A batch server may reject a *Locate Batch Job Request* for other implementation-defined reasons.

78355 *3.2.3.6 Modify Batch Job Request*

78356 Batch clients modify (alter) the attributes of a batch job by making a request to the server that
78357 manages the batch job. Such a request is called a *Modify Batch Job Request*.

78358 A batch server shall reject a *Modify Batch Job Request* if any of the following statements are true:

78359 The user of the batch client is not authorized to make the requested modification to the
78360 batch job.

78361 The designated job is not managed by the batch server.

78362 The requested modification is inconsistent with the state of the batch job.

78363 An unrecognized resource is requested for a batch job in an execution queue.

78364 A batch server may reject a *Modify Batch Job Request* for other implementation-defined reasons.
78365 The method used to determine whether the user of a client is authorized to perform the
78366 requested action is implementation-defined.

78367 A batch server that accepts a *Modify Batch Job Request* shall modify all the specified attributes of
78368 the batch job. A batch server that rejects a *Modify Batch Job Request* shall modify none of the

attributes of the batch job.

If the servicing by a batch server of an otherwise valid request would result in no change, then the batch server shall indicate successful completion of the request.

3.2.3.7 *Move Batch Job Request*

A batch client can request that a batch server move a batch job to another destination. Such a request is called a *Move Batch Job Request*.

A batch server shall reject a *Move Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to remove the designated job from the queue in which the batch job resides.
- The user of the batch client is not authorized to move the designated job to the destination.
- The designated job is not managed by the batch server.
- The designated job is in the EXITING state.
- The destination is inaccessible.

A batch server can reject a *Move Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Move Batch Job Request* shall perform the following services:

- Queue the designated job at the destination.
- Remove the designated job from the queue in which the batch job resides.

If the destination resides on another batch server, the batch server shall queue the batch job at the destination by sending a *Queue Batch Job Request* to the other server. If the *Queue Batch Job Request* fails, the batch server shall reject the *Move Batch Job Request*. If the *Queue Batch Job Request* succeeds, the batch server shall remove the batch job from its queue.

The batch server shall not modify any attributes of the batch job.

3.2.3.8 *Queue Batch Job Request*

A batch queue is controlled by one and only one batch server. A batch server is said to own the queues that it controls. Batch clients make requests of batch servers to have jobs queued. Such a request is called a *Queue Batch Job Request*.

A batch server requested to queue a batch job for which the queue is not specified shall select an implementation-defined queue for the batch job. Such a queue is called the ``default queue'' of the batch server. The implementation shall provide the means for a batch administrator to specify the default queue. The queue, whether specified or defaulted, is called the ``target queue''.

A batch server shall reject a *Queue Batch Job Request* if any of the following statements are true:

- The client is not authorized to create a batch job in the target queue.
- The request specifies a queue that does not exist on the batch server.
- The target queue is an execution queue and the batch server cannot satisfy a resource requirement of the batch job.

78407 The target queue is an execution queue and an unrecognized resource is requested.

78408 78409 The target queue is an execution queue, the batch server does not support checkpointing, and the value of the *Checkpoint* attribute of the batch job is not NO_CHECKPOINT.

78410 The job requires access to a user identifier that the batch client is not authorized to access.

78411 A batch server may reject a *Queue Batch Job Request* for other implementation-defined reasons.

78412 78413 78414 78415 78416 A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_O_QUEUE value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the name of the target queue. Once set, no server shall change the value of PBS_O_QUEUE, even if the batch job is moved to another queue.

78417 78418 78419 A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBID value is missing from the value of the *Variable_List* attribute shall add that variable to the list and set the value to the batch job identifier assigned by the server in the format:

78420 `sequence_number.server`

78421 78422 78423 A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBNAME value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the *Job_Name* attribute of the batch job.

78424 3.2.3.9 Batch Queue Status Request

78425 78426 A batch client can request that a batch server respond with the status and attributes of a queue. Such a request is called a *Batch Queue Status Request*.

78427 78428 A batch server shall reject a *Batch Queue Status Request* if any of the following statements are true:

78429 The user of the batch client is not authorized to query the status of the designated queue.

78430 The designated queue does not exist on the batch server.

78431 78432 78433 A batch server may reject a *Batch Queue Status Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

78434 78435 A batch server that accepts a *Batch Queue Status Request* shall return a *Batch Queue Status Reply* to the batch client.

78436 3.2.3.10 Release Batch Job Request

78437 78438 A batch client can request that the server remove one or more holds from a batch job. Such a request is called a *Release Batch Job Request*.

78439 A batch server shall reject a *Release Batch Job Request* if any of the following statements are true:

78440 78441 The user of the batch client is not authorized to remove one or more of the requested holds from the batch job.

78442 The batch server does not manage the specified job.

78443 78444 78445 A batch server may reject a *Release Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

78446 A batch server that accepts a *Release Batch Job Request* shall remove each type of hold listed in the

Release Batch Job Request, that is present, from the value of the *Hold_Types* attribute of the batch job.

3.2.3.11 Rerun Batch Job Request

To rerun a batch job is to kill the session leader of the batch job and leave the batch job eligible for re-execution. A batch client can request that a batch server rerun a batch job. Such a request is called *Rerun Batch Job Request*.

A batch server shall reject a *Rerun Batch Job Request* if any of the following statements are true:

The user of the batch client is not authorized to rerun the designated job.

The *Rerunable* attribute of the designated job has the value FALSE.

The designated job is not in the RUNNING state.

The batch server does not manage the designated job.

A batch server may reject a *Rerun Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that rejects a *Rerun Batch Job Request* shall in no way modify the execution of the batch job.

A batch server that accepts a request to rerun a batch job shall perform the following services:

Requeue the batch job in the execution queue in which it was executing.

Send a SIGKILL signal to the process group of the session leader of the batch job.

An implementation may indicate to the batch job owner that the batch job has been rerun. Whether and how the batch job owner is notified that a batch job is rerun is implementation-defined.

A batch server that reruns a batch job may send other implementation-defined signals to the session leader of the batch job prior to sending the SIGKILL signal.

A batch server may preferentially select a rerun job for execution. Whether rerun jobs shall be selected for execution before other jobs is implementation-defined.

3.2.3.12 Select Batch Jobs Request

A batch client can request from a batch server a list of jobs managed by that server that match a list of selection criteria. Such a request is called a *Select Batch Jobs Request*. All the batch jobs managed by the batch server that receives the request are candidates for selection.

A batch server that accepts a *Select Batch Jobs Request* shall return a list of zero or more job identifiers that correspond to jobs that meet the selection criteria.

If the batch client is not authorized to query the status of a batch job, the batch server shall not select the batch job.

78481 *3.2.3.13 Server Shutdown Request*

78482 A batch server is defined to have shut down when it does not respond to requests from clients
78483 and does not perform deferred services for jobs. A batch client can request that a batch server
78484 shut down. Such a request is called a *Server Shutdown Request*.

78485 A batch server shall reject a *Server Shutdown Request* from a client that is not authorized to shut
78486 down the batch server. The method used to determine whether the user of a client is authorized
78487 to perform the requested action is implementation-defined.

78488 A batch server may reject a *Server Shutdown Request* for other implementation-defined reasons.
78489 The reasons for which a *Server Shutdown Request* may be rejected are implementation-defined.

78490 At server shutdown, a batch server shall do, in order of preference, one of the following:

78491 If checkpointing is implemented and the batch job is checkpointable, then checkpoint the
78492 batch job and requeue it.

78493 If the batch job is rerunnable, then requeue the batch job to be rerun (restarted from the
78494 beginning).

78495 Abort the batch job.

78496 *3.2.3.14 Server Status Request*

78497 A batch client can request that a batch server respond with the status and attributes of the batch
78498 server. Such a request is called a *Server Status Request*.

78499 A batch server shall reject a *Server Status Request* if the following statement is true:

78500 The user of the batch client is not authorized to query the status of the designated server.

78501 A batch server may reject a *Server Status Request* for other implementation-defined reasons. The
78502 method used to determine whether the user of a client is authorized to perform the requested
78503 action is implementation-defined.

78504 A batch server that accepts a *Server Status Request* shall return a *Server Status Reply* to the batch
78505 client.

78506 *3.2.3.15 Signal Batch Job Request*

78507 A batch client can request that a batch server signal the session leader of a batch job. Such a
78508 request is called a *Signal Batch Job Request*.

78509 A batch server shall reject a *Signal Batch Job Request* if any of the following statements are true:

78510 The user of the batch client is not authorized to signal the batch job.

78511 The job is not in the RUNNING state.

78512 The batch server does not manage the designated job.

78513 The requested signal is not supported by the implementation.

78514 A batch server may reject a *Signal Batch Job Request* for other implementation-defined reasons.
78515 The method used to determine whether the user of a client is authorized to perform the
78516 requested action is implementation-defined.

78517 A batch server that accepts a request to signal a batch job shall send the signal requested by the
78518 batch client to the process group of the session leader of the batch job.

78519 *3.2.3.16 Track Batch Job Request*

78520 *Track Batch Job Request* is an optional feature of batch servers. If an implementation supports
78521 *Track Batch Job Request*, the statements in this section apply and the configuration variable
78522 POSIX2_PBS_TRACK shall be set to 1.

78523 *Track Batch Job Request* provides a method for tracking the current location of a batch job. Clients
78524 may use the tracking information to determine the batch server that should receive a batch
78525 server request.

78526 If *Track Batch Job Request* is supported by a batch server, then when the batch server queues a
78527 batch job as a result of a *Queue Batch Job Request*, and the batch server is not the batch server that
78528 created the batch job, the batch server shall send a *Track Batch Job Request* to the batch server that
78529 created the job.

78530 If *Track Batch Job Request* is supported by a batch server, then the *Track Batch Job Request* may also
78531 be sent to other servers as a backup to the primary server. The method by which backup servers
78532 are specified is implementation-defined.

78533 If *Track Batch Job Request* is supported by a batch server that receives a *Track Batch Job Request*,
78534 then the batch server shall record the current location of the batch job as contained in the
78535 request.

78536 3.3 Common Behavior for Batch Environment Utilities

78537 3.3.1 Batch Job Identifier

78538 A utility shall recognize *job_identifier*s of the format:

78539 `[sequence_number][.server_name][@server]`

78540 where:

78541 *sequence_number* An integer that, when combined with *server_name*, provides a batch job
78542 identifier that is unique within the batch system.

78543 *server_name* The name of the batch server to which the batch job was originally submitted.

78544 *server* The name of the batch server that is currently managing the batch job.

78545 If the application omits the batch *server_name* portion of a batch job identifier, a utility shall use
78546 the name of a default batch server.

78547 If the application omits the batch *server* portion of a batch job identifier, a utility shall use:

78548 The batch server indicated by *server_name*, if present

78549 The name of the default batch server

78550 The name of the batch server that is currently managing the batch job

78551 If only @*server* is specified, then the status of all jobs owned by the user on the requested server
78552 is listed.

78553 The means by which a utility determines the default batch server is implementation-defined.

78554 If the application presents the batch *server* portion of a batch job identifier to a utility, the utility
78555 shall send the request to the specified server.

A strictly conforming application shall use the syntax described for the job identifier. Whenever a batch job identifier is specified whose syntax is not recognized by an implementation, then a message for each error that occurs shall be written to standard error and the utility shall exit with an exit status greater than zero.

When a batch job identifier is supplied as an argument to a batch utility and the *server_name* portion of the batch job identifier is omitted, then the utility shall use the name of the default batch server.

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is omitted, then the utility shall use either:

The name of the default batch server

or:

The name of the batch server that is currently managing the batch job

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is specified, then the utility shall send the required *Batch Server Request* to the specified server.

3.3.2 Destination

The utility shall recognize a *destination* of the format:

```
[queue][@server]
```

where:

queue The name of a valid execution or routing queue at the batch server denoted by @*server*, defined as a string of up to 15 alphanumeric characters in the portable character set (see XBD Section 6.1, on page 125) where the first character is alphabetic.

server The name of a batch server, defined as a string of alphanumeric characters in the portable character set.

If the application omits the batch *server* portion of a destination, then the utility shall use either:

The name of the default batch server

or:

The name of the batch server that is currently managing the batch job

The means by which a utility determines the default batch server is implementation-defined.

If the application omits the *queue* portion of a destination, then the utility shall use the name of the default queue at the batch server chosen. The means by which a batch server determines its default queue is implementation-defined. If a destination is specified in the *queue@server* form, then the utility shall use the specified queue at the specified server.

A strictly conforming application shall use the syntax described for a destination. Whenever a destination is specified whose syntax is not recognized by an implementation, then a message shall be written to standard error and the utility shall exit with an exit status greater than zero.

3.3.3 Multiple Keyword-Value Pairs

For each option that can have multiple keyword-value pair arguments, the following rules shall apply. Examples of options that can have list-oriented option-arguments are **–u** *value@keyword* and **–l** *keyword=value*.

1. If a batch utility is presented with a list-oriented option-argument for which a keyword has a corresponding value that begins with a single or double-quote, then the utility shall stop interpreting the input stream for delimiters until a second single or double-quote, respectively, is encountered. This feature allows some flexibility for a <comma> (`','`) or <equals-sign> (`'='`) to be part of the value string for a particular keyword; for example:

   ```
   keywd1='val1,val2',keywd2="val3,val4"
   ```

   Note: This may require the user to escape the quotes as in the following command:

   ```
   foo –xkeywd1=\'val1,val2\',keywd2=\"val3,val4\"
   ```

2. If a batch server is presented with a list-oriented attribute that has a keyword that was encountered earlier in the list, then the later entry for that keyword shall replace the earlier entry.

3. If a batch server is presented with a list-oriented attribute that has a keyword without any corresponding value of the form *keyword=* or *@keyword* and the same keyword was encountered earlier in the list, then the prior entry for that keyword shall be ignored by the batch server.

4. If a batch utility is expecting a list-oriented option-argument entry of the form *keyword=value*, but is presented with an entry of the form *keyword* without any corresponding *value*, then the entry shall be treated as though a default value of NULL was assigned (that is, *keyword*=NULL) for entry parsing purposes. The utility shall include only the keyword, not the NULL value, in the associated job attribute.

5. If a batch utility is expecting a list-oriented option-argument entry of the form *value@keyword*, but is presented with an entry of the form *value* without any corresponding *keyword*, then the entry shall be treated as though a keyword of NULL was assigned (that is, *value*@NULL) for entry parsing purposes. The utility shall include only the value, not the NULL keyword, in the associated job attribute.

6. A batch server shall accept a list-oriented attribute that has multiple occurrences of the same keyword, interpreting the keywords, in order, with the last value encountered taking precedence over prior instances of the same keyword. This rule allows, but does not require, a batch utility to preprocess the attribute to remove duplicate keywords.

7. If a batch utility is presented with multiple list-oriented option-arguments on the command line or in script directives, or both, for a single option, then the utility shall concatenate, in order, any command line keyword and value pairs to the end of any directive keyword and value pairs separated by a single <comma> to produce a single string that is an equivalent, valid option-argument. The resulting string shall be assigned to the associated attribute of the batch job (after optionally removing duplicate entries as described in item 6).

78633 *Chapter 4*

78634 # *Utilities*

78635 This chapter contains the definitions of the utilities, as follows:

78636 Mandatory utilities that are present on every conformant system

78637 Optional utilities that are present only on systems supporting the associated option; see
78638 Section 1.7.1 (on page 7) for information on the options in this volume of POSIX.1-2017

NAME

admin — create and administer SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI

```
admin −i[name] [−n] [−a login] [−d flag] [−e login] [−f flag]
    [−m mrlist] [−r rel] [−t[name] [−y[comment]] newfile

admin −n [−a login] [−d flag] [−e login] [−f flag] [−m mrlist]
    [−t[name]] [−y[comment]] newfile...

admin [−a login] [−d flag] [−m mrlist] [−r rel] [−t[name]] file...

admin −h file...

admin −z file...
```

DESCRIPTION

The *admin* utility shall create new SCCS files or change parameters of existing ones. If a named file does not exist, it shall be created, and its parameters shall be initialized according to the specified options. Parameters not initialized by an option shall be assigned a default value. If a named file does exist, parameters corresponding to specified options shall be changed, and other parameters shall be left as is.

All SCCS filenames supplied by the application shall be of the form s.*filename*. New SCCS files shall be given read-only permission mode. Write permission in the parent directory is required to create a file. All writing done by *admin* shall be to a temporary *x-file*, named x.*filename* (see *get*) created with read-only mode if *admin* is creating a new SCCS file, or created with the same mode as that of the SCCS file if the file already exists. After successful execution of *admin*, the SCCS file shall be removed (if it exists), and the *x-file* shall be renamed with the name of the SCCS file. This ensures that changes are made to the SCCS file only if no errors occur.

The *admin* utility shall also use a transient lock file (named z.*filename*), which is used to prevent simultaneous updates to the SCCS file; see *get*.

OPTIONS

The *admin* utility shall conform to XBD Section 12.2 (on page 216), except that the **−i**, **−t**, and **−y** options have optional option-arguments. These optional option-arguments shall not be presented as separate arguments. The following options are supported:

−n Create a new SCCS file. When **−n** is used without **−i**, the SCCS file shall be created with control information but without any file data.

−i[*name***]** Specify the *name* of a file from which the text for a new SCCS file shall be taken. The text constitutes the first delta of the file (see the **−r** option for the delta numbering scheme). If the **−i** option is used, but the *name* option-argument is omitted, the text shall be obtained by reading the standard input. If this option is omitted, the SCCS file shall be created with control information but without any file data. The **−i** option implies the **−n** option.

−r *SID* Specify the SID of the initial delta to be inserted. This SID shall be a trunk SID; that is, the branch and sequence numbers shall be zero or missing. The level number is optional, and defaults to 1.

−t[*name***]** Specify the *name* of a file from which descriptive text for the SCCS file shall be taken. In the case of existing SCCS files (neither **−i** nor **−n** is specified):

78681 A **−t** option without a *name* option-argument shall cause the removal of
78682 descriptive text (if any) currently in the SCCS file.

78683 A **−t** option with a *name* option-argument shall cause the text (if any) in the
78684 named file to replace the descriptive text (if any) currently in the SCCS file.

78685 **−f** *flag* Specify a *flag*, and, possibly, a value for the *flag*, to be placed in the SCCS file.
78686 Several **−f** options may be supplied on a single *admin* command line.
78687 Implementations shall recognize the following flags and associated values:

78688 **b** Allow use of the **−b** option on a *get* command to create branch deltas.

78689 **c***ceil* Specify the highest release (that is, ceiling), a number less than or equal to
78690 9 999, which may be retrieved by a *get* command for editing. The default
78691 value for an unspecified **c** flag shall be 9 999.

78692 **f***floor* Specify the lowest release (that is, floor), a number greater than 0 but less
78693 than 9 999, which may be retrieved by a *get* command for editing. The
78694 default value for an unspecified **f** flag shall be 1.

78695 **d***SID* Specify the default delta number (SID) to be used by a *get* command.

78696 **i***str* Treat the ``No ID keywords'' message issued by *get* or *delta* as a fatal error.
78697 In the absence of this flag, the message is only a warning. The message is
78698 issued if no SCCS identification keywords (see *get*) are found in the text
78699 retrieved or stored in the SCCS file. If a value is supplied, the application
78700 shall ensure that the keywords exactly match the given string; however,
78701 the string shall contain a keyword, and no embedded <newline>
78702 characters.

78703 **j** Allow concurrent *get* commands for editing on the same SID of an SCCS
78704 file. This allows multiple concurrent updates to the same version of the
78705 SCCS file.

78706 **l***list* Specify a *list* of releases to which deltas can no longer be made (that is, *get*
78707 **−e** against one of these locked releases fails). Conforming applications
78708 shall use the following syntax to specify a *list*. Implementations may
78709 accept additional forms as an extension:

78710 `<list> ::= a | <range-list>`
78711 `<range-list> ::= <range> | <range-list>, <range>`
78712 `<range> ::= <SID>`

78713 The character *a* in the *list* shall be equivalent to specifying all releases for
78714 the named SCCS file. The non-terminal <*SID*> in range shall be the delta
78715 number of an existing delta associated with the SCCS file.

78716 **n** Cause *delta* to create a null delta in each of those releases (if any) being
78717 skipped when a delta is made in a new release (for example, in making
78718 delta 5.1 after delta 2.7, releases 3 and 4 are skipped). These null deltas
78719 shall serve as anchor points so that branch deltas may later be created
78720 from them. The absence of this flag shall cause skipped releases to be
78721 nonexistent in the SCCS file, preventing branch deltas from being created
78722 from them in the future. During the initial creation of an SCCS file, the **n**
78723 flag may be ignored; that is, if the **−r** option is used to set the release
78724 number of the initial SID to a value greater than 1, null deltas need not be
78725 created for the ``skipped'' releases.

78726 **q***text* Substitute user-definable *text* for all occurrences of the %**Q**% keyword in
78727 the SCCS file text retrieved by *get*.

78728 **m***mod* Specify the module name of the SCCS file substituted for all occurrences
78729 of the %**M**% keyword in the SCCS file text retrieved by *get*. If the **m** flag
78730 is not specified, the value assigned shall be the name of the SCCS file with
78731 the leading `'.'` removed.

78732 **t***type* Specify the *type* of module in the SCCS file substituted for all occurrences
78733 of the %**Y**% keyword in the SCCS file text retrieved by *get*.

78734 **v***pgm* Cause *delta* to prompt for modification request (MR) numbers as the
78735 reason for creating a delta. The optional value specifies the name of an
78736 MR number validation program. (If this flag is set when creating an SCCS
78737 file, the application shall ensure that the **m** option is also used even if its
78738 value is null.)

78739 −**d** *flag* Remove (delete) the specified *flag* from an SCCS file. Several −**d** options may be
78740 supplied on a single *admin* command. See the −**f** option for allowable *flag* names.
78741 (The **l***list* flag gives a *list* of releases to be unlocked. See the −**f** option for further
78742 description of the **l** flag and the syntax of a *list*.)

78743 −**a** *login* Specify a *login* name, or numerical group ID, to be added to the list of users who
78744 may make deltas (changes) to the SCCS file. A group ID shall be equivalent to
78745 specifying all *login* names common to that group ID. Several −**a** options may be
78746 used on a single *admin* command line. As many *login*s, or numerical group IDs, as
78747 desired may be on the list simultaneously. If the list of users is empty, then anyone
78748 may add deltas. If *login* or group ID is preceded by a `'!'`, the users so specified
78749 shall be denied permission to make deltas.

78750 −**e** *login* Specify a *login* name, or numerical group ID, to be erased from the list of users
78751 allowed to make deltas (changes) to the SCCS file. Specifying a group ID is
78752 equivalent to specifying all *login* names common to that group ID. Several −**e**
78753 options may be used on a single *admin* command line.

78754 −**y**[*comment*] Insert the *comment* text into the SCCS file as a comment for the initial delta in a
78755 manner identical to that of *delta*. In the POSIX locale, omission of the −**y** option
78756 shall result in a default comment line being inserted in the form:

78757 `"date and time created %s %s by %s", <`*date*`>, <`*time*`>, <`*login*`>`

78758 where <*date*> is expressed in the format of the *date* utility's `%y/%m/%d` conversion
78759 specification, <*time*> in the format of the *date* utility's `%T` conversion specification
78760 format, and <*login*> is the login name of the user creating the file.

78761 −**m** *mrlist* Insert the list of modification request (MR) numbers into the SCCS file as the
78762 reason for creating the initial delta in a manner identical to *delta*. The application
78763 shall ensure that the **v** flag is set and the MR numbers are validated if the **v** flag has
78764 a value (the name of an MR number validation program). A diagnostic message
78765 shall be written if the **v** flag is not set or MR validation fails.

78766 −**h** Check the structure of the SCCS file and compare the newly computed checksum
78767 with the checksum that is stored in the SCCS file. If the newly computed checksum
78768 does not match the checksum in the SCCS file, a diagnostic message shall be
78769 written.

78770 **−z** Recompute the SCCS file checksum and store it in the first line of the SCCS file (see
78771 the **−h** option above). Note that use of this option on a truly corrupted file may
78772 prevent future detection of the corruption.

78773 **OPERANDS**

78774 The following operands shall be supported:

78775 *file* A pathname of an existing SCCS file or a directory. If *file* is a directory, the *admin*
78776 utility shall behave as though each file in the directory were specified as a named
78777 file, except that non-SCCS files (last component of the pathname does not begin
78778 with **s.**) and unreadable files shall be silently ignored.

78779 *newfile* A pathname of an SCCS file to be created.

78780 If exactly one *file* or *newfile* operand appears, and it is `'−'`, the standard input shall be read; each
78781 line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-
78782 SCCS files and unreadable files shall be silently ignored.

78783 **STDIN**

78784 The standard input shall be a text file used only if **−i** is specified without an option-argument or
78785 if a *file* or *newfile* operand is specified as `'−'`. If the first character of any standard input line is
78786 <SOH> in the POSIX locale, the results are unspecified.

78787 **INPUT FILES**

78788 The existing SCCS files shall be text files of an unspecified format.

78789 The application shall ensure that the file named by the **−i** option's *name* option-argument shall
78790 be a text file; if the first character of any line in this file is <SOH> in the POSIX locale, the results
78791 are unspecified. If this file contains more than 99 999 lines, the number of lines recorded in the
78792 header for this file shall be 99 999 for this delta.

78793 **ENVIRONMENT VARIABLES**

78794 The following environment variables shall affect the execution of *admin*:

78795 *LANG* Provide a default value for the internationalization variables that are unset or null.
78796 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
78797 variables used to determine the values of locale categories.)

78798 *LC_ALL* If set to a non-empty string value, override the values of all the other
78799 internationalization variables.

78800 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
78801 characters (for example, single-byte as opposed to multi-byte characters in
78802 arguments and input files).

78803 *LC_MESSAGES*
78804 Determine the locale that should be used to affect the format and contents of
78805 diagnostic messages written to standard error and the contents of the default **−y**
78806 comment.

78807 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

78808 **ASYNCHRONOUS EVENTS**

78809 Default.

78810 **STDOUT**

78811 Not used.

78812 **STDERR**

78813 The standard error shall be used only for diagnostic messages.

78814 **OUTPUT FILES**

78815 Any SCCS files created shall be text files of an unspecified format. During processing of a *file*, a
78816 locking *z-file*, as described in *get* (on page 2823), may be created and deleted.

78817 **EXTENDED DESCRIPTION**

78818 None.

78819 **EXIT STATUS**

78820 The following exit values shall be returned:

78821 0 Successful completion.

78822 >0 An error occurred.

78823 **CONSEQUENCES OF ERRORS**

78824 Default.

78825 **APPLICATION USAGE**

78826 It is recommended that directories containing SCCS files be writable by the owner only, and that
78827 SCCS files themselves be read-only. The mode of the directories should allow only the owner to
78828 modify SCCS files contained in the directories. The mode of the SCCS files prevents any
78829 modification at all except by SCCS commands.

78830 **EXAMPLES**

78831 None.

78832 **RATIONALE**

78833 None.

78834 **FUTURE DIRECTIONS**

78835 None.

78836 **SEE ALSO**

78837 *delta*, *get*, *prs*, *what*

78838 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

78839 **CHANGE HISTORY**

78840 First released in Issue 2.

78841 **Issue 6**

78842 The normative text is reworded to avoid use of the term ``must'' for application requirements,
78843 and to emphasize the term ``shall'' for implementation requirements.

78844 The grammar is updated.

78845 The Open Group Base Resolution bwg2001-007 is applied, adding new text to the INPUT FILES
78846 section warning that the maximum lines recorded in the file is 99 999.

78847 The Open Group Base Resolution bwg2001-009 is applied, amending the description of the **−h**
78848 option.

NAME

alias ‡'define or display aliases

SYNOPSIS

```
alias [alias-name[=string]...]
```

DESCRIPTION

The *alias* utility shall create or redefine alias definitions or write the values of existing alias definitions to standard output. An alias definition provides a string value that shall replace a command name when it is encountered; see Section 2.3.1 (on page 2348).

An alias definition shall affect the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this volume of POSIX.1-2017, the alias definition shall not affect the parent process of the current shell nor any utility environment invoked by the shell; see Section 2.12 (on page 2381).

OPTIONS

None.

OPERANDS

The following operands shall be supported:

alias-name Write the alias definition to standard output.

alias-name=string
Assign the value of *string* to the alias *alias-name*.

If no operands are given, all alias definitions shall be written to standard output.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *alias*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

78889 **STDOUT**

78890 The format for displaying aliases (when no operands or only *name* operands are specified) shall
78891 be:

78892 `"%s=%s\n", name, value`

78893 The *value* string shall be written with appropriate quoting so that it is suitable for reinput to the
78894 shell. See the description of shell quoting in Section 2.2 (on page 2346).

78895 **STDERR**

78896 The standard error shall be used only for diagnostic messages.

78897 **OUTPUT FILES**

78898 None.

78899 **EXTENDED DESCRIPTION**

78900 None.

78901 **EXIT STATUS**

78902 The following exit values shall be returned:

78903 0 Successful completion.

78904 >0 One of the *name* operands specified did not have an alias definition, or an error occurred.

78905 **CONSEQUENCES OF ERRORS**

78906 Default.

78907 **APPLICATION USAGE**

78908 None.

78909 **EXAMPLES**

78910 1. Create a short alias for a commonly used *ls* command:

78911 ```
alias lf="ls -CF"
```

78912 2. Create a simple ``redo'' command to repeat previous entries in the command history file:

78913 ```
alias r='fc -s'
```

78914 3. Use 1K units for *du*:

78915 ```
alias du=du\ -k
```

78916 4. Set up *nohup* so that it can deal with an argument that is itself an alias name:

78917 ```
alias nohup="nohup "
```

78918 **RATIONALE**

78919 The *alias* description is based on historical KornShell implementations. Known differences exist
78920 between that and the C shell. The KornShell version was adopted to be consistent with all the
78921 other KornShell features in this volume of POSIX.1-2017, such as command line editing.

78922 Since *alias* affects the current shell execution environment, it is generally provided as a shell
78923 regular built-in.

78924 Historical versions of the KornShell have allowed aliases to be exported to scripts that are
78925 invoked by the same shell. This is triggered by the *alias* **−x** flag; it is allowed by this volume of
78926 POSIX.1-2017 only when an explicit extension such as **−x** is used. The standard developers
78927 considered that aliases were of use primarily to interactive users and that they should normally
78928 not affect shell scripts called by those users; functions are available to such scripts.

Historical versions of the KornShell had not written aliases in a quoted manner suitable for reentry to the shell, but this volume of POSIX.1-2017 has made this a requirement for all similar output. Therefore, consistency was chosen over this detail of historical practice.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.9.5 (on page 2374)

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

Issue 7

The *alias* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The first example is changed to remove the creation of an alias for a standard utility that alters its behavior to be non-conforming.

78948 **NAME**

78949 ar — create and maintain library archives

78950 **SYNOPSIS**

78951 SD
```
ar −d [−v] archive file...
```

78952 XSI
```
ar −m [−v] archive file...
ar −m −a [−v] posname archive file...
ar −m −b [−v] posname archive file...

```
ar −t [−v] [−s] archive [file...]
```

78963 XSI
```
ar −x [−v] [−sCT] archive [file...]
```

78964 **DESCRIPTION**

78965 The *ar* utility is part of the Software Development Utilities option.

78966 The *ar* utility can be used to create and maintain groups of files combined into an archive. Once
78967 an archive has been created, new files can be added, and existing files in an archive can be
78968 extracted, deleted, or replaced. When an archive consists entirely of valid object files, the
78969 implementation shall format the archive so that it is usable as a library for link editing (see *c99*
78970 and *fort77*). When some of the archived files are not valid object files, the suitability of the
78971 XSI archive for library use is undefined. If an archive consists entirely of printable files, the entire
78972 archive shall be printable.

78973 When *ar* creates an archive, it creates administrative information indicating whether a symbol
78974 table is present in the archive. When there is at least one object file that *ar* recognizes as such in
78975 the archive, an archive symbol table shall be created in the archive and maintained by *ar*; it is
78976 used by the link editor to search the archive. Whenever the *ar* utility is used to create or update
78977 the contents of such an archive, the symbol table shall be rebuilt. The **−s** option shall force the
78978 symbol table to be rebuilt.

78979 All *file* operands can be pathnames. However, files within archives shall be named by a filename,
78980 which is the last component of the pathname used when the file was entered into the archive.
78981 The comparison of *file* operands to the names of files in archives shall be performed by
78982 comparing the last component of the operand to the name of the file in the archive.

78983 It is unspecified whether multiple files in the archive may be identically named. In the case of
78984 XSI such files, however, each *file* and *posname* operand shall match only the first file in the archive
78985 having a name that is the same as the last component of the operand.

OPTIONS

The *ar* utility shall conform to XBD Section 12.2 (on page 216), except for Guideline 9.

The following options shall be supported:

XSI **−a** Position new files in the archive after the file named by the *posname* operand.

XSI **−b** Position new files in the archive before the file named by the *posname* operand.

−c Suppress the diagnostic message that is written to standard error by default when the archive *archive* is created.

XSI **−C** Prevent extracted files from replacing like-named files in the file system. This option is useful when **−T** is also used, to prevent truncated filenames from replacing files with the same prefix.

−d Delete one or more *file*s from *archive*.

XSI **−i** Position new files in the archive before the file in the archive named by the *posname* operand (equivalent to **−b**).

XSI **−m** Move the named files in the archive. The **−a**, **−b**, or **−i** options with the *posname* operand indicate the position; otherwise, move the names files in the archive to the end of the archive.

−p Write the contents of the *file*s in the archive named by *file* operands from *archive* to the standard output. If no *file* operands are specified, the contents of all files in the archive shall be written in the order of the archive.

XSI **−q** Append the named files to the end of the archive. In this case *ar* does not check whether the added files are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece by piece.

−r Replace or add *file*s to *archive*. If the archive named by *archive* does not exist, a new archive shall be created and a diagnostic message shall be written to standard error (unless the **−c** option is specified). If no *file*s are specified and the *archive* exists, the results are undefined. Files that replace existing files in the archive shall not change the order of the archive. Files that do not replace existing files in the archive shall be appended to the archive XSI unless a **−a**, **−b**, or **−i** option specifies another position.

XSI **−s** Force the regeneration of the archive symbol table even if *ar* is not invoked with an option that modifies the archive contents. This option is useful to restore the archive symbol table after it has been stripped; see *strip*.

−t Write a table of contents of *archive* to the standard output. Only the files specified by the *file* operands shall be included in the written list. If no *file* operands are specified, all files in *archive* shall be included in the order of the archive.

XSI **−T** Allow filename truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long shall be an error; a diagnostic message shall be written and the file shall not be extracted.

−u Update older files in the archive. When used with the **−r** option, files in the archive shall be replaced only if the corresponding *file* has a modification time that is at least as new as the modification time of the file in the archive.

79027 **−v** Give verbose output. When used with the option characters **−d**, **−r**, or **−x**, write a
79028 detailed file-by-file description of the archive creation and maintenance activity, as
79029 described in the STDOUT section.

79030 When used with **−p**, write the name of the file in the archive to the standard output
79031 before writing the file in the archive itself to the standard output, as described in
79032 the STDOUT section.

79033 When used with **−t**, include a long listing of information about the files in the
79034 archive, as described in the STDOUT section.

79035 **−x** Extract the files in the archive named by the *file* operands from *archive*. The
79036 contents of the archive shall not be changed. If no *file* operands are given, all files
79037 in the archive shall be extracted. The modification time of each file extracted shall
79038 be set to the time the file is extracted from the archive.

79039 **OPERANDS**

79040 The following operands shall be supported:

79041 *archive* A pathname of the archive.

79042 *file* A pathname. Only the last component shall be used when comparing against the
79043 names of files in the archive. If two or more *file* operands have the same last
79044 pathname component (basename), the results are unspecified. The
79045 implementation's archive format shall not truncate valid filenames of files added
79046 to or replaced in the archive.

79047 XSI *posname* The name of a file in the archive, used for relative positioning; see options **−m** and
79048 **−r**.

79049 **STDIN**

79050 Not used.

79051 **INPUT FILES**

79052 The archive named by *archive* shall be a file in the format created by *ar* **−r**.

79053 **ENVIRONMENT VARIABLES**

79054 The following environment variables shall affect the execution of *ar*:

79055 *LANG* Provide a default value for the internationalization variables that are unset or null.
79056 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
79057 variables used to determine the values of locale categories.)

79058 *LC_ALL* If set to a non-empty string value, override the values of all the other
79059 internationalization variables.

79060 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
79061 characters (for example, single-byte as opposed to multi-byte characters in
79062 arguments and input files).

79063 *LC_MESSAGES*
79064 Determine the locale that should be used to affect the format and contents of
79065 diagnostic messages written to standard error.

79066 *LC_TIME* Determine the format and content for date and time strings written by *ar* **−tv**.

79067 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

79068 *TMPDIR* Determine the pathname that overrides the default directory for temporary files, if
79069 any.

79070 *TZ* Determine the timezone used to calculate date and time strings written by *ar* **–tv**.
79071 If *TZ* is unset or null, an unspecified default timezone shall be used.

79072 **ASYNCHRONOUS EVENTS**

79073 Default.

79074 **STDOUT**

79075 If the **–d** option is used with the **–v** option, the standard output format shall be:

79076 `"d – %s\n", <file>`

79077 where *file* is the operand specified on the command line.

79078 If the **–p** option is used with the **–v** option, *ar* shall precede the contents of each file with:

79079 `"\n<%s>\n\n", <file>`

79080 where *file* is the operand specified on the command line, if *file* operands were specified, and the
79081 name of the file in the archive if they were not.

79082 If the **–r** option is used with the **–v** option:

79083 If *file* is already in the archive, the standard output format shall be:

79084 `"r – %s\n", <file>`

79085 where <*file*> is the operand specified on the command line.

79086 If *file* is not already in the archive, the standard output format shall be:

79087 `"a – %s\n", <file>`

79088 where <*file*> is the operand specified on the command line.

79089 If the **–t** option is used, *ar* shall write the names of the files in the archive to the standard output
79090 in the format:

79091 `"%s\n", <file>`

79092 where *file* is the operand specified on the command line, if *file* operands were specified, or the
79093 name of the file in the archive if they were not.

79094 If the **–t** option is used with the **–v** option, the standard output format shall be:

```
79095 "%s %u/%u %u %s %d %d:%d %d %s\n", <member mode>, <user ID>,
79096     <group ID>, <number of bytes in member>,
79097     <abbreviated month>, <day-of-month>, <hour>,
79098     <minute>, <year>, <file>
```

79099 where:

79100 <*file*> Shall be the operand specified on the command line, if *file* operands were specified,
79101 or the name of the file in the archive if they were not.

79102 <*member mode*>
79103 Shall be formatted the same as the <*file mode*> string defined in the STDOUT
79104 section of *ls*, except that the first character, the <*entry type*>, is not used; the string
79105 represents the file mode of the file in the archive at the time it was added to or
79106 replaced in the archive.

79107 The following represent the last-modification time of a file when it was most recently added to
79108 or replaced in the archive:

79109 *<abbreviated month>*
79110 Equivalent to the format of the `%b` conversion specification format in *date*.

79111 *<day-of-month>*
79112 Equivalent to the format of the `%e` conversion specification format in *date*.

79113 *<hour>* Equivalent to the format of the `%H` conversion specification format in *date*.

79114 *<minute>* Equivalent to the format of the `%M` conversion specification format in *date*.

79115 *<year>* Equivalent to the format of the `%Y` conversion specification format in *date*.

79116 When *LC_TIME* does not specify the POSIX locale, a different format and order of presentation
79117 of these fields relative to each other may be used in a format appropriate in the specified locale.

79118 If the **−x** option is used with the **−v** option, the standard output format shall be:

79119 `"x - %s\n", <file>`

79120 where *file* is the operand specified on the command line, if *file* operands were specified, or the
79121 name of the file in the archive if they were not.

79122 **STDERR**

79123 The standard error shall be used only for diagnostic messages. The diagnostic message about
79124 creating a new archive when **−c** is not specified shall not modify the exit status.

79125 **OUTPUT FILES**

79126 Archives are files with unspecified formats.

79127 **EXTENDED DESCRIPTION**

79128 None.

79129 **EXIT STATUS**

79130 The following exit values shall be returned:

79131 0 Successful completion.

79132 >0 An error occurred.

79133 **CONSEQUENCES OF ERRORS**

79134 Default.

79135 **APPLICATION USAGE**

79136 None.

79137 **EXAMPLES**

79138 None.

79139 **RATIONALE**

79140 The archive format is not described. It is recognized that there are several known *ar* formats,
79141 which are not compatible. The *ar* utility is included, however, to allow creation of archives that
79142 are intended for use only on one machine. The archive is specified as a file, and it can be moved
79143 as a file. This does allow an archive to be moved from one machine to another machine that uses
79144 the same implementation of *ar*.

79145 Utilities such as *pax* (and its forebears *tar* and *cpio*) also provide portable ``archives''. This is a not
79146 a duplication; the *ar* utility is included to provide an interface primarily for *make* and the
79147 compilers, based on a historical model.

In historical implementations, the **−q** option (available on XSI-conforming systems) is known to execute quickly because *ar* does not check on whether the added members are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece-by-piece. These remarks may but need not remain true for a brand new implementation of this utility; hence, these remarks have been moved into the RATIONALE.

BSD implementations historically required applications to provide the **−s** option whenever the archive was supposed to contain a symbol table. As in this volume of POSIX.1-2017, System V historically creates or updates an archive symbol table whenever an object file is removed from, added to, or updated in the archive.

The OPERANDS section requires what might seem to be true without specifying it: the archive cannot truncate the filenames below {NAME_MAX}. Some historical implementations do so, however, causing unexpected results for the application. Therefore, this volume of POSIX.1-2017 makes the requirement explicit to avoid misunderstandings.

According to the System V documentation, the options **−dmpqrtx** are not required to begin with a <hyphen-minus> (`'−'`). This volume of POSIX.1-2017 requires that a conforming application use the leading <hyphen-minus>.

The archive format used by the 4.4 BSD implementation is documented in this RATIONALE as an example:

> A file created by *ar* begins with the ``magic'' string `"!<arch>\n"`. The rest of the archive is made up of objects, each of which is composed of a header for a file, a possible filename, and the file contents. The header is portable between machine architectures, and, if the file contents are printable, the archive is itself printable.
>
> The header is made up of six ASCII fields, followed by a two-character trailer. The fields are the object name (16 characters), the file last modification time (12 characters), the user and group IDs (each 6 characters), the file mode (8 characters), and the file size (10 characters). All numeric fields are in decimal, except for the file mode, which is in octal.
>
> The modification time is the file *st_mtime* field. The user and group IDs are the file *st_uid* and *st_gid* fields. The file mode is the file *st_mode* field. The file size is the file *st_size* field. The two-byte trailer is the string "`<newline>".
>
> Only the name field has any provision for overflow. If any filename is more than 16 characters in length or contains an embedded space, the string `"#1/"` followed by the ASCII length of the name is written in the name field. The file size (stored in the archive header) is incremented by the length of the name. The name is then written immediately following the archive header.
>
> Any unused characters in any of these fields are written as <space> characters. If any fields are their particular maximum number of characters in length, there is no separation between the fields.
>
> Objects in the archive are always an even number of bytes long; files that are an odd number of bytes long are padded with a <newline>, although the size in the header does not reflect this.

The *ar* utility description requires that (when all its members are valid object files) *ar* produce an object code library, which the linkage editor can use to extract object modules. If the linkage editor needs a symbol table to permit random access to the archive, *ar* must provide it; however, *ar* does not require a symbol table.

The BSD **−o** option was omitted. It is a rare conforming application that uses *ar* to extract object

code from a library with concern for its modification time, since this can only be of importance to *make*. Hence, since this functionality is not deemed important for applications portability, the modification time of the extracted files is set to the current time.

There is at least one known implementation (for a small computer) that can accommodate only object files for that system, disallowing mixed object and other files. The ability to handle any type of file is not only historical practice for most implementations, but is also a reasonable expectation.

Consideration was given to changing the output format of *ar* **–tv** to the same format as the output of *ls* **–l**. This would have made parsing the output of *ar* the same as that of *ls*. This was rejected in part because the current *ar* format is commonly used and changes would break historical usage. Second, *ar* gives the user ID and group ID in numeric format separated by a <slash>. Changing this to be the user name and group name would not be correct if the archive were moved to a machine that contained a different user database. Since *ar* cannot know whether the archive was generated on the same machine, it cannot tell what to report.

The text on the **–ur** option combination is historical practice ‡since one filename can easily represent two different files (for example, **/a/foo** and **/b/foo**), it is reasonable to replace the file in the archive even when the modification time in the archive is identical to that in the file system.

FUTURE DIRECTIONS

None.

c99, *date*, *fort77*, *pax*, *strip*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216), **<unistd.h>**, description of {POSIX_NO_TRUNC}

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the Software Development Utilities option.

The STDOUT description is changed for the **–v** option to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #198 is applied, changing the description to consistently use ``file'' to refer to a file in the file system hierarchy, ``archive'' to refer to the archive being operated upon by the *ar* utility, and ``file in the archive'' to refer to a copy of a file that is contained in the archive.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/10 is applied, making corrections to the SYNOPSIS. The change was needed since the **–a**, **–b**, and **–i** options are mutually-exclusive, and *posname* is required if any of these options is specified.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/11 is applied, correcting the description of the two-byte trailer in RATIONALE which had missed out a backquote. The correct trailer is a backquote followed by a <newline>.

Issue 7

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The description of the **−t** option is changed to say ``Only the files specified ...''.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0057 [584] is applied.

NAME

asa — interpret carriage-control characters

SYNOPSIS

FR
```
asa [file...]
```

DESCRIPTION

The *asa* utility shall write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences in an implementation-defined manner.

The first character of every line shall be removed from the input, and the following actions are performed.

If the character removed is:

<space> The rest of the line is output without change.

0 A <newline> is output, then the rest of the input line.

1 One or more implementation-defined characters that causes an advance to the next page shall be output, followed by the rest of the input line.

+ The <newline> of the previous line shall be replaced with one or more implementation-defined characters that causes printing to return to column position 1, followed by the rest of the input line. If the `'+'` is the first character in the input, it shall be equivalent to <space>.

The action of the *asa* utility is unspecified upon encountering any character other than those listed above as the first character in a line.

OPTIONS

None.

OPERANDS

file A pathname of a text file used for input. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *asa*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The standard output shall be the text from the input file modified as described in the DESCRIPTION section.

STDERR
None.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 All input files were output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
None.

EXAMPLES

1. The following command:

   ```
   asa file
   ```

   permits the viewing of *file* (created by a program using FORTRAN-style carriage-control characters) on a terminal.

2. The following command:

   ```
   a.out | asa | lp
   ```

   formats the FORTRAN output of **a.out** and directs it to the printer.

RATIONALE
The *asa* utility is needed to map ``standard'' FORTRAN 77 output into a form acceptable to contemporary printers. Usually, *asa* is used to pipe data to the *lp* utility; see *lp*.

This utility is generally used only by FORTRAN programs. The standard developers decided to retain *asa* to avoid breaking the historical large base of FORTRAN applications that put carriage-control characters in their output files. There is no requirement that a system have a FORTRAN compiler in order to run applications that need *asa*.

Historical implementations have used an ASCII <form-feed> in response to a 1 and an ASCII <carriage-return> in response to a `'+'`. It is suggested that implementations treat characters other than 0, 1, and `'+'` as <space> in the absence of any compelling reason to do otherwise.

However, the action is listed here as ``unspecified'', permitting an implementation to provide extensions to access fast multiple-line slewing and channel seeking in a non-portable manner.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the FORTRAN Runtime Utilities option.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

at ‡'execute commands at a later time

SYNOPSIS

```
at [−m] [−f file] [−q queuename] −t time_arg
at [−m] [−f file] [−q queuename] timespec...
at −r at_job_id...
at −l −q queuename
at −l [at_job_id...]
```

DESCRIPTION

The *at* utility shall read commands from standard input and group them together as an *at-job*, to be executed at a later time.

The at-job shall be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask, and other implementation-defined execution-time attributes in effect when the *at* utility is executed shall be retained and used when the at-job is executed.

When the at-job is submitted, the *at_job_id* and scheduled time shall be written to standard error. The *at_job_id* is an identifier that shall be a string consisting solely of alphanumeric characters and the <period> character. The *at_job_id* shall be assigned by the system when the job is scheduled such that it uniquely identifies a particular job.

User notification and the processing of the job's standard output and standard error are described under the **−m** option.

XSI Users shall be permitted to use *at* if their name appears in the file **at.allow** which is located in an implementation-defined directory. If that file does not exist, the file **at.deny**, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to *at*. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only **at.deny** exists and is empty, global usage shall be permitted. The **at.allow** and **at.deny** files shall consist of one user name per line.

OPTIONS

The *at* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−f *file* Specify the pathname of a file to be used as the source of the at-job, instead of standard input.

−l (The letter ell.) Report all jobs scheduled for the invoking user if no *at_job_id* operands are specified. If *at_job_id*s are specified, report only information for these jobs. The output shall be written to standard output.

−m Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job shall be mailed to the user as well, unless redirected elsewhere. Mail shall be sent even if the job produces no output.

If **−m** is not used, the job's standard output and standard error shall be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the implementation need not notify the user of the job's completion.

79382 −**q** *queuename*

79383 Specify in which queue to schedule a job for submission. When used with the −**l**
79384 option, limit the search to that particular queue. By default, at-jobs shall be
79385 scheduled in queue *a*. In contrast, queue *b* shall be reserved for batch jobs; see
79386 *batch*. The meanings of all other *queuename*s are implementation-defined. If −**q** is
79387 specified along with either of the −**t** *time_arg* or *timespec* arguments, the results are
79388 unspecified.

79389 −**r** Remove the jobs with the specified *at_job_id* operands that were previously
79390 scheduled by the *at* utility.

79391 −**t** *time_arg* Submit the job to be run at the time specified by the *time* option-argument, which
79392 the application shall ensure has the format as specified by the *touch* −**t** *time* utility.

79393 **OPERANDS**

79394 The following operands shall be supported:

79395 *at_job_id* The name reported by a previous invocation of the *at* utility at the time the job was
79396 scheduled.

79397 *timespec* Submit the job to be run at the date and time specified. All of the *timespec* operands
79398 are interpreted as if they were separated by <space> characters and concatenated,
79399 and shall be parsed as described in the grammar at the end of this section. The date
79400 and time shall be interpreted as being in the timezone of the user (as determined
79401 by the *TZ* variable), unless a timezone name appears as part of *time*, below.

79402 In the POSIX locale, the following describes the three parts of the time specification
79403 string. All of the values from the *LC_TIME* categories in the POSIX locale shall be
79404 recognized in a case-insensitive manner.

79405 *time* The time can be specified as one, two, or four digits. One-digit and
79406 two-digit numbers shall be taken to be hours; four-digit numbers to
79407 be hours and minutes. The time can alternatively be specified as two
79408 numbers separated by a <colon>, meaning *hour*:*minute*. An AM/PM
79409 indication (one of the values from the **am_pm** keywords in the
79410 *LC_TIME* locale category) can follow the time; otherwise, a 24-hour
79411 clock time shall be understood. A timezone name can also follow to
79412 further qualify the time. The acceptable timezone names are
79413 implementation-defined, except that they shall be case-insensitive
79414 and the string **utc** is supported to indicate the time is in Coordinated
79415 Universal Time. In the POSIX locale, the *time* field can also be one of
79416 the following tokens:

79417 **midnight** Indicates the time 12:00 am (00:00).

79418 **noon** Indicates the time 12:00 pm.

79419 **now** Indicates the current day and time. Invoking *at* <**now**>
79420 shall submit an at-job for potentially immediate
79421 execution (that is, subject only to unspecified
79422 scheduling delays).

79423 *date* An optional *date* can be specified as either a month name (one of the
79424 values from the **mon** or **abmon** keywords in the *LC_TIME* locale
79425 category) followed by a day number (and possibly year number
79426 preceded by a comma), or a day of the week (one of the values from
79427 the **day** or **abday** keywords in the *LC_TIME* locale category). In the

POSIX locale, two special days shall be recognized:

today Indicates the current day.

tomorrow Indicates the day following the current day.

If no *date* is given, **today** shall be assumed if the given time is greater than the current time, and **tomorrow** shall be assumed if it is less. If the given month is less than the current month (and no year is given), next year shall be assumed.

increment The optional *increment* shall be a number preceded by a <plus-sign> ('+') and suffixed by one of the following: **minutes**, **hours**, **days**, **weeks**, **months**, or **years**. (The singular forms shall also be accepted.) The keyword **next** shall be equivalent to an increment number of +1. For example, the following are equivalent commands:

```
at 2pm + 1 week
at 2pm next week
```

The following grammar describes the precise format of *timespec* in the POSIX locale. The general conventions for this style of grammar are described in Section 1.3 (on page 2335). This formal syntax shall take precedence over the preceding text syntax description. The longest possible token or delimiter shall be recognized at a given point. When used in a *timespec*, white space shall also delimit tokens.

```
%token hr24clock_hr_min
%token hr24clock_hour
/*
  An hr24clock_hr_min is a one, two, or four-digit number. A one-digit
  or two-digit number constitutes an hr24clock_hour. An hr24clock_hour
  may be any of the single digits [0,9], or may be double digits, ranging
  from [00,23]. If an hr24clock_hr_min is a four-digit number, the
  first two digits shall be a valid hr24clock_hour, while the last two
  represent the number of minutes, from [00,59].
*/

%token wallclock_hr_min

            | "month" | "months"
            | "year" | "years"
            ;
```

STDIN

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 2345). The standard input shall only be used if no **–f** *file* option is specified.

INPUT FILES

See the STDIN section.

XSI The text files **at.allow** and **at.deny**, which are located in an implementation-defined directory, shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the *at* and *batch* utilities.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *at*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
: Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LC_TIME
: Determine the format and contents for date and time strings written and accepted by *at*.

SHELL
: Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, *sh* shall be used. If it is set to a value other than a name for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use the login shell from the user database; or any of the preceding accompanied by a warning diagnostic about which was chosen.

TZ
: Determine the timezone. The job shall be submitted for execution at the time specified by *timespec* or **–t** *time* relative to the timezone specified by the *TZ* variable. If *timespec* specifies a timezone, it shall override *TZ*. If *timespec* does not specify a timezone and *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

In the POSIX locale, the following shall be written to the standard output for each job when jobs are listed in response to the **–l** option:

```
"%s\t%s\n", at_job_id, <date>
```

where *date* shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the *TZ* variable).

STDERR

In the POSIX locale, the following shall be written to standard error when a job has been successfully submitted:

```
"job %s at %s\n", at_job_id, <date>
```

where *date* has the same format as that described in the STDOUT section. Neither this, nor warning messages concerning the selection of the command interpreter, shall be considered a diagnostic that changes the exit status.

Diagnostic messages, if any, shall be written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The *at* utility successfully submitted, removed, or listed a job or jobs.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The job shall not be scheduled, removed, or listed.

APPLICATION USAGE

The format of the *at* command line shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps, and priority inherited from the invoking environment are lost.

Some implementations do not allow substitution of different shells using *SHELL*. System V systems, for example, have used the login shell value for the user in **/etc/passwd**. To select reliably another command interpreter, the user must include it as part of the script, such as:

```
$ at 1800
myshell myscript
EOT
job ... at ...
$
```

EXAMPLES

1. This sequence can be used at a terminal:

   ```
   at −m 0730 tomorrow
   sort < file >outfile
   EOT
   ```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

   ```
   at now + 1 hour <<!
   diff file1 file2 2>&1 >outfile | mailx mygroup
   !
   ```

3. To have a job reschedule itself, *at* can be invoked from within the at-job. For example, this daily processing script named **my.daily** runs every day (although *crontab* is a more appropriate vehicle for such work):

   ```
   # my.daily runs every day
   daily processing
   at now tomorrow < my.daily
   ```

4. The spacing of the three portions of the POSIX locale *timespec* is quite flexible as long as there are no ambiguities. Examples of various times and operand presentation include:

   ```
   at 0815am Jan 24
   at 8 :15amjan24
   at now "+ 1day"
   at 5 pm FRIday
   at '17
   ```

```
79654                utc+
79655                30minutes'
```

RATIONALE

The *at* utility reads from standard input the commands to be executed at a later time. It may be useful to redirect standard output and standard error within the specified commands.

The **−t** *time* option was added as a new capability to support an internationalized way of specifying a time for execution of the submitted job.

Early proposals added a ``jobname'' concept as a way of giving submitted jobs names that are meaningful to the user submitting them. The historical, system-specified *at_job_id* gives no indication of what the job is. Upon further reflection, it was decided that the benefit of this was not worth the change in historical interface. The *at* functionality is useful in simple environments, but in large or complex situations, the functionality provided by the Batch Services option is more suitable.

The **−q** option historically has been an undocumented option, used mainly by the *batch* utility.

The System V **−m** option was added to provide a method for informing users that an at-job had completed. Otherwise, users are only informed when output to standard error or standard output are not redirected.

The behavior of *at* <**now**> was changed in an early proposal from being unspecified to submitting a job for potentially immediate execution. Historical BSD *at* implementations support this. Historical System V implementations give an error in that case, but a change to the System V versions should have no backwards-compatibility ramifications.

On BSD-based systems, a **−u** *user* option has allowed those with appropriate privileges to access the work of other users. Since this is primarily a system administration feature and is not universally implemented, it has been omitted. Similarly, a specification for the output format for a user with appropriate privileges viewing the queues of other users has been omitted.

The **−f** *file* option from System V is used instead of the BSD method of using the last operand as the pathname. The BSD method is ambiguous ‡does:

```
at 1200 friday
```

mean the same thing if there is a file named **friday** in the current directory?

The *at_job_id* is composed of a limited character set in historical practice, and it is mandated here to invalidate systems that might try using characters that require shell quoting or that could not be easily parsed by shell scripts.

The *at* utility varies between System V and BSD systems in the way timezones are used. On System V systems, the *TZ* variable affects the at-job submission times and the times displayed for the user. On BSD systems, *TZ* is not taken into account. The BSD behavior is easily achieved with the current specification. If the user wishes to have the timezone default to that of the system, they merely need to issue the *at* command immediately following an unsetting or null assignment to *TZ*. For example:

```
TZ= at noon ...
```

gives the desired BSD result.

While the *yacc*-like grammar specified in the OPERANDS section is lexically unambiguous with respect to the digit strings, a lexical analyzer would probably be written to look for and return digit strings in those cases. The parser could then check whether the digit string returned is a valid *day_number*, *year_number*, and so on, based on the context.

FUTURE DIRECTIONS

None.

batch, *crontab*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

> If **−m** is not used, the job's standard output and standard error are provided to the user by mail.

The effects of using the **−q** and **−t** options as defined in the IEEE P1003.2b draft standard are specified.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

The *at* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the *at* utility.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

awk — pattern scanning and processing language

SYNOPSIS

```
awk [−F sepstring] [−v assignment]... program [argument...]
awk [−F sepstring] −f progfile [−f progfile]... [−v assignment]...
     [argument...]
```

DESCRIPTION

The *awk* utility shall execute programs written in the *awk* programming language, which is specialized for textual data manipulation. An *awk* program is a sequence of patterns and corresponding actions. When input is read that matches a pattern, the action associated with that pattern is carried out.

Input shall be interpreted as a sequence of records. By default, a record is a line, less its terminating <newline>, but this can be changed by using the **RS** built-in variable. Each record of input shall be matched in turn against each pattern in the program. For each pattern matched, the associated action shall be executed.

The *awk* utility shall interpret each input record as a sequence of fields where, by default, a field is a string of non-<blank> non-<newline> characters. This default <blank> and <newline> field delimiter can be changed by using the **FS** built-in variable or the **−F** *sepstring* option. The *awk* utility shall denote the first field in a record $1, the second $2, and so on. The symbol $0 shall refer to the entire record; setting any other field causes the re-evaluation of $0. Assigning to $0 shall reset the values of all other fields and the **NF** built-in variable.

OPTIONS

The *awk* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−F *sepstring* Define the input field separator. This option shall be equivalent to:

```
−v FS=sepstring
```

except that if **−F** *sepstring* and **−v** `FS=`*sepstring* are both used, it is unspecified whether the **FS** assignment resulting from **−F** *sepstring* is processed in command line order or is processed after the last **−v** `FS=`*sepstring*. See the description of the **FS** built-in variable, and how it is used, in the EXTENDED DESCRIPTION section.

−f *progfile* Specify the pathname of the file *progfile* containing an *awk* program. A pathname of `'−'` shall denote the standard input. If multiple instances of this option are specified, the concatenation of the files specified as *progfile* in the order specified shall be the *awk* program. The *awk* program can alternatively be specified in the command line as a single argument.

−v *assignment*
The application shall ensure that the *assignment* argument is in the same form as an *assignment* operand. The specified variable assignment shall occur prior to executing the *awk* program, including the actions associated with **BEGIN** patterns (if any). Multiple occurrences of this option can be specified.

OPERANDS

The following operands shall be supported:

program If no **−f** option is specified, the first operand to *awk* shall be the text of the *awk* program. The application shall supply the *program* operand as a single argument to *awk*. If the text does not end in a <newline>, *awk* shall interpret the text as if it did.

argument Either of the following two types of *argument* can be intermixed:

file A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `'-'`, the standard input shall be used.

assignment An operand that begins with an <underscore> or alphabetic character from the portable character set (see the table in XBD Section 6.1, on page 125), followed by a sequence of underscores, digits, and alphabetics from the portable character set, followed by the `'='` character, shall specify a variable assignment rather than a pathname. The characters before the `'='` represent the name of an *awk* variable; if that name is an *awk* reserved word (see Grammar, on page 2500) the behavior is undefined. The characters following the <equals-sign> shall be interpreted as if they appeared in the *awk* program preceded and followed by a double-quote (`'"'`) character, as a **STRING** token (see Grammar, on page 2500), except that if the last character is an unescaped <backslash>, it shall be interpreted as a literal <backslash> rather than as the first character of the sequence `"\""`. The variable shall be assigned the value of that **STRING** token and, if appropriate, shall be considered a *numeric string* (see Expressions in awk, on page 2485), the variable shall also be assigned its numeric value. Each such variable assignment shall occur just prior to the processing of the following *file*, if any. Thus, an assignment before the first *file* argument shall be executed after the **BEGIN** actions (if any), while an assignment after the last *file* argument shall occur before the **END** actions (if any). If there are no *file* arguments, assignments shall be executed before processing the standard input.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'-'`, or if a *progfile* option-argument is `'-'`; see the INPUT FILES section. If the *awk* program contains no actions and no patterns, but is otherwise a valid *awk* program, standard input and any *file* operands shall not be read and *awk* shall exit with a return status of zero.

INPUT FILES

Input files to the *awk* program from any of the following sources shall be text files:

Any *file* operands or their equivalents, achieved by modifying the *awk* variables **ARGV** and **ARGC**

Standard input in the absence of any *file* operands

Arguments to the **getline** function

Whether the variable **RS** is set to a value other than a <newline> or not, for these files, implementations shall support records terminated with the specified separator up to {LINE_MAX} bytes and may support longer records.

If **−f** *progfile* is specified, the application shall ensure that the files named by each of the *progfile* option-arguments are text files and their concatenation, in the same order as they appear in the arguments, is an *awk* program.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *awk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions and in comparisons of string values.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the identification of characters as letters, and the mapping of uppercase and lowercase characters for the **toupper** and **tolower** functions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values, and formatting numeric output. Regardless of locale, the <period> character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments).

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path when looking for commands executed by *system*(*expr*), or input and output pipes; see XBD Chapter 8 (on page 173).

In addition, all environment variables shall be visible via the *awk* variable **ENVIRON**.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The nature of the output files depends on the *awk* program.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The nature of the output files depends on the *awk* program.

EXTENDED DESCRIPTION

Overall Program Structure

An *awk* program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted.

A missing pattern shall match any record of input, and a missing action shall be equivalent to:

```
{ print }
```

Execution of the *awk* program shall start by first executing the actions associated with all **BEGIN** patterns in the order they occur in the program. Then each *file* operand (or standard input if no files were specified) shall be processed in turn by reading data from the file until a record separator is seen (<newline> by default). Before the first reference to a field in the record is evaluated, the record shall be split into fields, according to the rules in Regular Expressions (on page 2491), using the value of **FS** that was current at the time the record was read. Each pattern in the program then shall be evaluated in the order of occurrence, and the action associated with each pattern that matches the current record executed. The action for a matching pattern shall be executed before evaluating subsequent patterns. Finally, the actions associated with all **END** patterns shall be executed in the order they occur in the program.

Expressions in awk

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators shall be evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while lvalue represents any entity that can be assigned to (that is, on the left side of an assignment operator). The precise syntax of expressions is given in Grammar (on page 2500).

Table 4-1 Expressions in Decreasing Precedence in *awk*

Syntax	Name	Type of Result	Associativity
`( expr )`	Grouping	Type of *expr*	N/A
`$expr`	Field reference	String	N/A
`lvalue ++`	Post-increment	Numeric	N/A
`lvalue --`	Post-decrement	Numeric	N/A
`++ lvalue`	Pre-increment	Numeric	N/A
`-- lvalue`	Pre-decrement	Numeric	N/A
`expr ^ expr`	Exponentiation	Numeric	Right
`! expr`	Logical not	Numeric	N/A
`+ expr`	Unary plus	Numeric	N/A
`- expr`	Unary minus	Numeric	N/A
`expr * expr`	Multiplication	Numeric	Left
`expr / expr`	Division	Numeric	Left
`expr % expr`	Modulus	Numeric	Left

Syntax	Name	Type of Result	Associativity
expr + *expr*	Addition	Numeric	Left
expr − *expr*	Subtraction	Numeric	Left
expr expr	String concatenation	String	Left
expr < *expr*	Less than	Numeric	None
expr <= *expr*	Less than or equal to	Numeric	None
expr != *expr*	Not equal to	Numeric	None
expr == *expr*	Equal to	Numeric	None
expr > *expr*	Greater than	Numeric	None
expr >= *expr*	Greater than or equal to	Numeric	None
expr ~ *expr*	ERE match	Numeric	None
expr !~ *expr*	ERE non-match	Numeric	None
expr in *array*	Array membership	Numeric	Left
(*index*) in *array*	Multi-dimension array membership	Numeric	Left
expr && *expr*	Logical AND	Numeric	Left
expr || *expr*	Logical OR	Numeric	Left
expr1 ? *expr2* : *expr3*	Conditional expression	Type of selected *expr2* or *expr3*	Right
lvalue ^= *expr*	Exponentiation assignment	Numeric	Right
lvalue %= *expr*	Modulus assignment	Numeric	Right
lvalue *= *expr*	Multiplication assignment	Numeric	Right
lvalue /= *expr*	Division assignment	Numeric	Right
lvalue += *expr*	Addition assignment	Numeric	Right
lvalue −= *expr*	Subtraction assignment	Numeric	Right
lvalue = *expr*	Assignment	Type of *expr*	Right

Each expression shall have either a string value, a numeric value, or both. Except as stated for specific contexts, the value of an expression shall be implicitly converted to the type needed for the context in which it is used. A string value shall be converted to a numeric value either by the equivalent of the following calls to functions defined by the ISO C standard:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

or by converting the initial portion of the string to type **double** representation as follows:

> The input string is decomposed into two parts: an initial, possibly empty, sequence of white-space characters (as specified by *isspace*()) and a subject sequence interpreted as a floating-point constant.
>
> The expected form of the subject sequence is an optional '+' or '−' sign, then a non-empty sequence of digits optionally containing a <period>, then an optional exponent part. An exponent part consists of 'e' or 'E', followed by an optional sign, followed by one or more decimal digits.
>
> The sequence starting with the first digit or the <period> (whichever occurs first) is interpreted as a floating constant of the C language, and if neither an exponent part nor a <period> appears, a <period> is assumed to follow the last digit in the string. If the subject sequence begins with a <hyphen-minus>, the value resulting from the conversion is negated.

A numeric value that is exactly equal to the value of an integer (see Section 1.1.2, on page 2331)

shall be converted to a string by the equivalent of a call to the **sprintf** function (see String Functions, on page 2497) with the string `"%d"` as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value shall be converted to a string by the equivalent of a call to the **sprintf** function with the value of the variable **CONVFMT** as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. The result of the conversion is unspecified if the value of **CONVFMT** is not a floating-point format specification. This volume of POSIX.1-2017 specifies no explicit conversions between numbers and strings. An application can force an expression to be treated as a number by adding zero to it, or can force it to be treated as a string by concatenating the null string (`""`) to it.

A string value shall be considered a *numeric string* if it comes from one of the following:

1. Field variables
2. Input from the *getline*( ) function
3. **FILENAME**
4. **ARGV** array elements
5. **ENVIRON** array elements
6. Array elements created by the *split*( ) function
7. A command line variable assignment
8. Variable assignment from another numeric string variable

and an implementation-dependent condition corresponding to either case (a) or (b) below is met.

a. After the equivalent of the following calls to functions defined by the ISO C standard, *string_value_end* would differ from *string_value*, and any characters before the terminating null character in *string_value_end* would be <blank> characters:

```
char *string_value_end;
setlocale(LC_NUMERIC, "");
numeric_value = strtod (string_value, &string_value_end);
```

b. After all the following conversions have been applied, the resulting string would lexically be recognized as a **NUMBER** token as described by the lexical conventions in Grammar (on page 2500):

- All leading and trailing <blank> characters are discarded.
- If the first non-<blank> is `'+'` or `'−'`, it is discarded.
- Each occurrence of the decimal point character from the current locale is changed to a <period>.

In case (a) the numeric value of the *numeric string* shall be the value that would be returned by the *strtod*( ) call. In case (b) if the first non-<blank> is `'−'`, the numeric value of the *numeric string* shall be the negation of the numeric value of the recognized **NUMBER** token; otherwise, the numeric value of the *numeric string* shall be the numeric value of the recognized **NUMBER** token. Whether or not a string is a *numeric string* shall be relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero shall be treated as false and any other value shall be treated as true. Otherwise, a string value of the null string shall be treated as false and any other value shall be treated as true. A Boolean

context shall be one of the following:

The first subexpression of a conditional expression

An expression operated on by logical NOT, logical AND, or logical OR

The second expression of a **for** statement

The expression of an **if** statement

The expression of the **while** clause in either a **while** or **do**...**while** statement

An expression used as a pattern (as in Overall Program Structure)

All arithmetic shall follow the semantics of floating-point arithmetic as specified by the ISO C standard (see Section 1.1.2, on page 2331).

The value of the expression:

expr1 ^ *expr2*

shall be equivalent to the value returned by the ISO C standard function call:

pow(*expr1*, *expr2*)

The expression:

lvalue ^= *expr*

shall be equivalent to the ISO C standard expression:

lvalue = pow(lvalue, *expr*)

except that lvalue shall be evaluated only once. The value of the expression:

expr1 % *expr2*

shall be equivalent to the value returned by the ISO C standard function call:

fmod(*expr1*, *expr2*)

The expression:

lvalue %= *expr*

shall be equivalent to the ISO C standard expression:

lvalue = fmod(lvalue, *expr*)

except that lvalue shall be evaluated only once.

Variables and fields shall be set by the assignment statement:

lvalue = *expression*

and the type of *expression* shall determine the resulting variable type. The assignment includes the arithmetic assignments ("+=", "−=", "*=", "/=", "%=", "^=", "++", "−−") all of which shall produce a numeric result. The left-hand side of an assignment and the target of increment and decrement operators can be one of a variable, an array with index, or a field selector.

The *awk* language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They shall initially be empty, and their sizes shall change dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an lvalue and thus as an expression, as described in the grammar; see Grammar (on page 2500). Unsubscripted array names can be used in only the following contexts:

80015 A parameter in a function definition or function call

80016 80017 80018 The **NAME** token following any use of the keyword **in** as specified in the grammar (see Grammar, on page 2500); if the name used in this context is not an array name, the behavior is undefined

80019 80020 80021 80022 80023 80024 A valid array *index* shall consist of one or more <comma>-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because *awk* arrays are really one-dimensional, such a <comma>-separated list shall be converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the **SUBSEP** variable. Thus, the following two index operations shall be equivalent:

80025 `var[expr1, expr2, ... exprn]`

80026 `var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]`

80027 80028 80029 80030 The application shall ensure that a multi-dimensioned *index* used with the **in** operator is parenthesized. The **in** operator, which tests for the existence of a particular array element, shall not cause that element to exist. Any other reference to a nonexistent array element shall automatically create it.

80031 80032 80033 80034 80035 Comparisons (with the `'<'`, `"<="`, `"!="`, `"=="`, `'>'`, and `">="` operators) shall be made numerically if both operands are numeric, if one is numeric and the other has a string value that is a numeric string, or if one is numeric and the other has the uninitialized value. Otherwise, operands shall be converted to strings as required and a string comparison shall be made as follows:

80036 80037 80038 For the `"!="` and `"=="` operators, the strings should be compared to check if they are identical but may be compared using the locale-specific collation sequence to check if they collate equally.

80039 80040 For the other operators, the strings shall be compared using the locale-specific collation sequence.

80041 80042 The value of the comparison expression shall be 1 if the relation is true, or 0 if the relation is false.

80043 **Variables and Special Variables**

80044 80045 80046 80047 80048 80049 80050 80051 80052 80053 80054 Variables can be used in an *awk* program by referencing them. With the exception of function parameters (see User-Defined Functions, on page 2499), they are not explicitly declared. Function parameter names shall be local to the function; all other variable names shall be global. The same name shall not be used as both a function parameter name and as the name of a function or a special *awk* variable. The same name shall not be used both as a variable name with global scope and as the name of a function. The same name shall not be used within the same scope both as a scalar variable and as an array. Uninitialized variables, including scalar variables, array elements, and field variables, shall have an uninitialized value. An uninitialized value shall have both a numeric value of zero and a string value of the empty string. Evaluation of variables with an uninitialized value, to either string or numeric, shall be determined by the context in which they are used.

80055 80056 80057 80058 80059 Field variables shall be designated by a `'$'` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables can be created by assigning a value to them. References to nonexistent fields (that is, fields after $**NF**), shall evaluate to the uninitialized value. Such

references shall not create new fields. However, assigning to a nonexistent field (for example, $(**NF**+2)=5) shall increase the value of **NF**; create any intervening fields with the uninitialized value; and cause the value of $0 to be recomputed, with the fields being separated by the value of **OFS**. Each field variable shall have a string value or an uninitialized value when created. Field variables shall have the uninitialized value when created from $0 using **FS** and the variable does not contain any characters. If appropriate, the field variable shall be considered a numeric string (see Expressions in awk, on page 2485).

Implementations shall support the following other special variables that are set by *awk*:

ARGC The number of elements in the **ARGV** array.

ARGV An array of command line arguments, excluding options and the *program* argument, numbered from zero to **ARGC**–1.

The arguments in **ARGV** can be modified or added to; **ARGC** can be altered. As each input file ends, *awk* shall treat the next non-null element of **ARGV**, up to the current value of **ARGC**–1, inclusive, as the name of the next input file. Thus, setting an element of **ARGV** to null means that it shall not be treated as an input file. The name `'-'` indicates the standard input. If an argument matches the format of an *assignment* operand, this argument shall be treated as an *assignment* rather than a *file* argument.

CONVFMT The **printf** format for converting numbers to strings (except for output statements, where **OFMT** is used); `"%.6g"` by default.

ENVIRON An array representing the value of the environment, as described in the *exec* functions defined in the System Interfaces volume of POSIX.1-2017. The indices of the array shall be strings consisting of the names of the environment variables, and the value of each array element shall be a string consisting of the value of that variable. If appropriate, the environment variable shall be considered a *numeric string* (see Expressions in awk, on page 2485); the array element shall also have its numeric value.

In all cases where the behavior of *awk* is affected by environment variables (including the environment of any commands that *awk* executes via the **system** function or via pipeline redirections with the **print** statement, the **printf** statement, or the **getline** function), the environment used shall be the environment at the time *awk* began executing; it is implementation-defined whether any modification of **ENVIRON** affects this environment.

FILENAME A pathname of the current input file. Inside a **BEGIN** action the value is undefined. Inside an **END** action the value shall be the name of the last input file processed.

FNR The ordinal number of the current record in the current file. Inside a **BEGIN** action the value shall be zero. Inside an **END** action the value shall be the number of the last record processed in the last file processed.

FS Input field separator regular expression; a <space> by default.

NF The number of fields in the current record. Inside a **BEGIN** action, the use of **NF** is undefined unless a **getline** function without a *var* argument is executed previously. Inside an **END** action, **NF** shall retain the value it had for the last record read, unless a subsequent, redirected, **getline** function without a *var* argument is performed prior to entering the **END** action.

80105 **NR** The ordinal number of the current record from the start of input. Inside a **BEGIN**
80106 action the value shall be zero. Inside an **END** action the value shall be the number
80107 of the last record processed.

80108 **OFMT** The **printf** format for converting numbers to strings in output statements (see
80109 Output Statements, on page 2495); `"%.6g"` by default. The result of the conversion
80110 is unspecified if the value of **OFMT** is not a floating-point format specification.

80111 **OFS** The **print** statement output field separator; <space> by default.

80112 **ORS** The **print** statement output record separator; a <newline> by default.

80113 **RLENGTH** The length of the string matched by the **match** function.

80114 **RS** The first character of the string value of **RS** shall be the input record separator; a
80115 <newline> by default. If **RS** contains more than one character, the results are
80116 unspecified. If **RS** is null, then records are separated by sequences consisting of a
80117 <newline> plus one or more blank lines, leading or trailing blank lines shall not
80118 result in empty records at the beginning or end of the input, and a <newline> shall
80119 always be a field separator, no matter what the value of **FS** is.

80120 **RSTART** The starting position of the string matched by the **match** function, numbering from
80121 1. This shall always be equivalent to the return value of the **match** function.

80122 **SUBSEP** The subscript separator string for multi-dimensional arrays; the default value is
80123 implementation-defined.

80124 **Regular Expressions**

80125 The *awk* utility shall make use of the extended regular expression notation (see XBD Section 9.4,
80126 on page 188) except that it shall allow the use of C-language conventions for escaping special
80127 characters within the EREs, as specified in the table in XBD Chapter 5 (on page 121) (`'\\'`,
80128 `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) and the following table; these escape sequences
80129 shall be recognized both inside and outside bracket expressions. Note that records need not be
80130 separated by <newline> characters and string constants can contain <newline> characters, so
80131 even the `"\n"` sequence is valid in *awk* EREs. Using a <slash> character within an ERE requires
80132 the escaping shown in the following table.

Table 4-2 Escape Sequences in *awk*

Escape Sequence	Description	Meaning
`\"`	<backslash> <quotation-mark>	<quotation-mark> character
`\/`	<backslash> <slash>	<slash> character
`\ddd`	A <backslash> character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <backslash> for each byte.
`\c`	A <backslash> character followed by any character not described in this table or in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`).	Undefined

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `'~'` and `"!~"`. These operators shall interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `'~'` expression shall evaluate to a value of 1, and the `"!~"` expression shall evaluate to a value of 0. (The regular expression matching operation is as defined by the term matched in XBD Section 9.1 (on page 181), where a match occurs on any part of the string unless the regular expression is limited with the <circumflex> or <dollar-sign> special characters.) If the regular expression does not match the string, the `'~'` expression shall evaluate to a value of 0, and the `"!~"` expression shall evaluate to a value of 1. If the right-hand operand is any expression other than the lexical token **ERE**, the string value of the expression shall be interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions shall also be applied in determining the value of a string literal (the lexical token **STRING**), and thus shall be applied a second time when a string literal is used in this context.

When an **ERE** token appears as an expression in any context other than as the right-hand of the `'~'` or `"!~"` operator or as one of the built-in function arguments described below, the value of the resulting expression shall be the equivalent of:

```
$0 ~ /ere/
```

The *ere* argument to the **gsub**, **match**, **sub** functions, and the *fs* argument to the **split** function (see String Functions, on page 2497) shall be interpreted as extended regular expressions. These can be either **ERE** tokens or arbitrary expressions, and shall be interpreted in the same manner as the right-hand side of the `'~'` or `"!~"` operator.

An extended regular expression can be used to separate fields by assigning a string containing the expression to the built-in variable **FS**, either directly or as a consequence of using the **–F** *sepstring* option. The default value of the **FS** variable shall be a single <space>. The following describes **FS** behavior:

1. If **FS** is a null string, the behavior is unspecified.

2. If **FS** is a single character:
    a. If **FS** is <space>, skip leading and trailing <blank> and <newline> characters; fields shall be delimited by sets of one or more <blank> or <newline> characters.
    b. Otherwise, if **FS** is any other character *c*, fields shall be delimited by each single occurrence of *c*.
3. Otherwise, the string value of **FS** shall be considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression shall delimit fields.

Except for the `'~'` and `"!~"` operators, and in the **gsub**, **match**, **split**, and **sub** built-in functions, ERE matching shall be based on input records; that is, record separator characters (the first character of the value of the variable **RS**, <newline> by default) cannot be embedded in the expression, and no expression shall match the record separator character. If the record separator is not <newline>, <newline> characters embedded in the expression can be matched. For the `'~'` and `"!~"` operators, and in those four built-in functions, ERE matching shall be based on text strings; that is, any character (including <newline> and the record separator) can be embedded in the pattern, and an appropriate pattern shall match any character. However, in all *awk* ERE matching, the use of one or more NUL characters in the pattern, input record, or text string produces undefined results.

Patterns

A *pattern* is any valid *expression*, a range specified by two expressions separated by a comma, or one of the two special patterns **BEGIN** or **END**.

Special Patterns

The *awk* utility shall recognize two special patterns, **BEGIN** and **END**. Each **BEGIN** pattern shall be matched once and its associated action executed before the first record of input is read ‡’ except possibly by use of the **getline** function (see Input/Output and General Functions, on page 2498) in a prior **BEGIN** action ‡and before command line assignment is done. Each **END** pattern shall be matched once and its associated action executed after the last record of input has been read. These two patterns shall have associated actions.

BEGIN and **END** shall not combine with other patterns. Multiple **BEGIN** and **END** patterns shall be allowed. The actions associated with the **BEGIN** patterns shall be executed in the order specified in the program, as are the **END** actions. An **END** pattern can precede a **BEGIN** pattern in a program.

If an *awk* program consists of only actions with the pattern **BEGIN**, and the **BEGIN** action contains no **getline** function, *awk* shall exit without reading its input when the last statement in the last **BEGIN** action is executed. If an *awk* program consists of only actions with the pattern **END** or only actions with the patterns **BEGIN** and **END**, the input shall be read before the statements in the **END** actions are executed.

Expression Patterns

An expression pattern shall be evaluated as if it were an expression in a Boolean context. If the result is true, the pattern shall be considered to match, and the associated action (if any) shall be executed. If the result is false, the action shall not be executed.

Pattern Ranges

A pattern range consists of two expressions separated by a comma; in this case, the action shall be performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.

Actions

An action is a sequence of statements as shown in the grammar in Grammar (on page 2500). Any single statement can be replaced by a statement list enclosed in curly braces. The application shall ensure that statements in a statement list are separated by <newline> or <semicolon> characters. Statements in a statement list shall be executed sequentially in the order that they appear.

The *expression* acting as the conditional in an **if** statement shall be evaluated and if it is non-zero or non-null, the following statement shall be executed; otherwise, if **else** is present, the statement following the **else** shall be executed.

The **if**, **while**, **do**...**while**, **for**, **break**, and **continue** statements are based on the ISO C standard (see Section 1.1.2, on page 2331), except that the Boolean expressions shall be treated as described in Expressions in awk (on page 2485), and except in the case of:

```
for (variable in array)
```

which shall iterate, assigning each *index* of *array* to *variable* in an unspecified order. The results of adding new elements to *array* within such a **for** loop are undefined. If a **break** or **continue** statement occurs outside of a loop, the behavior is undefined.

The **delete** statement shall remove an individual array element. Thus, the following code deletes an entire array:

```
for (index in array)
    delete array[index]
```

The **next** statement shall cause all further processing of the current input record to be abandoned. The behavior is undefined if a **next** statement appears or is invoked in a **BEGIN** or **END** action.

The **exit** statement shall invoke all **END** actions in the order in which they occur in the program source and then terminate the program without reading further input. An **exit** statement inside an **END** action shall terminate the program without further execution of **END** actions. If an expression is specified in an **exit** statement, its numeric value shall be the exit status of *awk*, unless subsequent errors are encountered or a subsequent **exit** statement with an expression is executed.

Output Statements

Both **print** and **printf** statements shall write to standard output by default. The output shall be written to the location specified by *output_redirection* if one is supplied, as follows:

```
> expression
>> expression
| expression
```

In all cases, the *expression* shall be evaluated to produce a string that is used as a pathname into which to write (for `'>'` or `">>"`) or as a command to be executed (for `'|'`). Using the first two forms, if the file of that name is not currently open, it shall be opened, creating it if necessary and using the first form, truncating the file. The output then shall be appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value shall simply append output to the file. The file remains open until the **close** function (see Input/Output and General Functions, on page 2498) is called with an expression that evaluates to the same string value.

The third form shall write output onto a stream piped to the input of a command. The stream shall be created if no stream is currently open with the value of *expression* as its command name. The stream created shall be equivalent to one created by a call to the *popen*( ) function defined in the System Interfaces volume of POSIX.1-2017 with the value of *expression* as the *command* argument and a value of *w* as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall write output to the existing stream. The stream shall remain open until the **close** function (see Input/Output and General Functions, on page 2498) is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function defined in the System Interfaces volume of POSIX.1-2017.

As described in detail by the grammar in Grammar (on page 2500), these output statements shall take a <comma>-separated list of *expression*s referred to in the grammar by the non-terminal symbols **expr_list**, **print_expr_list**, or **print_expr_list_opt**. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The **print** statement shall write the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable **OFS** above), and terminated by the output record separator (see variable **ORS** above). All expression arguments shall be taken as strings, being converted if necessary; this conversion shall be as described in Expressions in awk (on page 2485), with the exception that the **printf** format in **OFMT** shall be used instead of the value in **CONVFMT**. An empty expression list shall stand for the whole input record ($0).

The **printf** statement shall produce output based on a notation similar to the File Format Notation used to describe file formats in this volume of POSIX.1-2017 (see XBD Chapter 5, on page 121). Output shall be produced as specified with the first *expression* argument as the string *format* and subsequent *expression* arguments as the strings *arg1* to *argn*, inclusive, with the following exceptions:

1. The *format* shall be an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The <space> in the *format* string, in any context other than a *flag* of a conversion specification, shall be treated as an ordinary character that is copied to the output.

2. If the character set contains a `'Δ'` character and that character appears in the *format* string, it shall be treated as an ordinary character that is copied to the output.

3. The *escape sequences* beginning with a <backslash> character shall be treated as sequences of ordinary characters that are copied to the output. Note that these same sequences shall be interpreted lexically by *awk* when they appear in literal strings, but they shall not be treated specially by the **printf** statement.
4. A *field width* or *precision* can be specified as the `'*'` character instead of a digit string. In this case the next argument from the expression list shall be fetched and its numeric value taken as the field width or precision.
5. The implementation shall not precede or follow output from the `d` or `u` conversion specifier characters with <blank> characters not specified by the *format* string.
6. The implementation shall not precede output from the `o` conversion specifier character with leading zeros not specified by the *format* string.
7. For the `c` conversion specifier character: if the argument has a numeric value, the character whose encoding is that value shall be output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value shall be output; if the string does not contain any characters, the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument shall be evaluated. With the exception of the `c` conversion specifier character, the value shall be converted (according to the rules specified in Expressions in awk, on page 2485) to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.
10. If any character sequence in the *format* string begins with a `'%'` character, but does not form a valid conversion specification, the behavior is unspecified.

Both **print** and **printf** can output at least {LINE_MAX} bytes.

Functions

The *awk* language has a variety of built-in functions: arithmetic, string, input/output, and general.

Arithmetic Functions

The arithmetic functions, except for **int**, shall be based on the ISO C standard (see Section 1.1.2, on page 2331). The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar (see Grammar, on page 2500) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `"[ ]"` brackets), such use is undefined.

atan2(y,x) Return arctangent of y/x in radians in the range $[-\pi,\pi]$.

cos(x) Return cosine of x, where x is in radians.

sin(x) Return sine of x, where x is in radians.

exp(x) Return the exponential function of x.

log(x) Return the natural logarithm of x.

sqrt(*x*) Return the square root of *x*.

int(*x*) Return the argument truncated to an integer. Truncation shall be toward 0 when *x*>0.

rand( ) Return a random number *n*, such that 0≤*n*<1.

srand([*expr*]) Set the seed value for *rand* to *expr* or use the time of day if *expr* is omitted. The previous seed value shall be returned.

String Functions

The string functions in the following list shall be supported. Although the grammar (see Grammar, on page 2500) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the "[ ]" brackets), such use is undefined.

gsub(*ere*, *repl*[, *in*])
Behave like **sub** (see below), except that it shall replace all occurrences of the regular expression (like the *ed* utility global substitute) in $0 or in the *in* argument, when specified.

index(*s*, *t*) Return the position, in characters, numbering from 1, in string *s* where string *t* first occurs, or zero if it does not occur at all.

length[([*s*])] Return the length, in characters, of its argument taken as a string, or of the whole record, $0, if there is no argument.

match(*s*, *ere*) Return the position, in characters, numbering from 1, in string *s* where the extended regular expression *ere* occurs, or zero if it does not occur at all. RSTART shall be set to the starting position (which is the same as the returned value), zero if no match is found; RLENGTH shall be set to the length of the matched string, –1 if no match is found.

split(*s*, *a*[, *fs*])
Split the string *s* into array elements *a*[1], *a*[2], ..., *a*[*n*], and return *n*. All elements of the array shall be deleted before the split is performed. The separation shall be done with the ERE *fs* or with the field separator **FS** if *fs* is not given. Each array element shall have a string value when created and, if appropriate, the array element shall be considered a numeric string (see Expressions in awk, on page 2485). The effect of a null string as the value of *fs* is unspecified.

sprintf(*fmt*, *expr*, *expr*, ...)
Format the expressions according to the **printf** format given by *fmt* and return the resulting string.

sub(*ere*, *repl*[, *in*])
Substitute the string *repl* in place of the first instance of the extended regular expression *ERE* in string *in* and return the number of substitutions. An <ampersand> ('&') appearing in the string *repl* shall be replaced by the string from *in* that matches the ERE. An <ampersand> preceded with a <backslash> shall be interpreted as the literal <ampersand> character. An occurrence of two consecutive <backslash> characters shall be interpreted as just a single literal <backslash> character. Any other occurrence of a <backslash> (for example, preceding any other character) shall be treated as a literal <backslash> character. Note that if *repl* is a string literal (the lexical token **STRING**; see Grammar, on page 2500), the handling of the <ampersand> character occurs after any lexical

processing, including any lexical <backslash>-escape sequence processing. If *in* is specified and it is not an lvalue (see Expressions in awk, on page 2485), the behavior is undefined. If *in* is omitted, *awk* shall use the current record ($0) in its place.

substr(*s*, *m*[, *n*])
Return the at most *n*-character substring of *s* that begins at position *m*, numbering from 1. If *n* is omitted, or if *n* specifies more characters than are left in the string, the length of the substring shall be limited by the length of the string *s*.

tolower(*s*) Return a string based on the string *s*. Each character in *s* that is an uppercase letter specified to have a **tolower** mapping by the *LC_CTYPE* category of the current locale shall be replaced in the returned string by the lowercase letter specified by the mapping. Other characters in *s* shall be unchanged in the returned string.

toupper(*s*) Return a string based on the string *s*. Each character in *s* that is a lowercase letter specified to have a **toupper** mapping by the *LC_CTYPE* category of the current locale is replaced in the returned string by the uppercase letter specified by the mapping. Other characters in *s* are unchanged in the returned string.

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined in Regular Expressions (on page 2491).

Input/Output and General Functions

The input/output and general functions are:

close(*expression*)
Close the file or pipe opened by a **print** or **printf** statement or a call to **getline** with the same string-valued *expression*. The limit on the number of open *expression* arguments is implementation-defined. If the close was successful, the function shall return zero; otherwise, it shall return non-zero.

expression | **getline** [*var*]
Read a record of input from a stream piped from the output of a command. The stream shall be created if no stream is currently open with the value of *expression* as its command name. The stream created shall be equivalent to one created by a call to the *popen*( ) function with the value of *expression* as the *command* argument and a value of *r* as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall read subsequent records from the stream. The stream shall remain open until the **close** function is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function. If *var* is omitted, $0 and **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered a numeric string (see Expressions in awk, on page 2485).

The **getline** operator can form ambiguous constructs when there are unparenthesized operators (including concatenate) to the left of the `'|'` (to the beginning of the expression containing **getline**). In the context of the `'$'` operator, `'|'` shall behave as if it had a lower precedence than `'$'`. The result of evaluating other operators is unspecified, and conforming applications shall parenthesize properly all such usages.

getline Set $0 to the next input record from the current input file. This form of **getline** shall set the **NF**, **NR**, and **FNR** variables.

getline *var* Set variable *var* to the next input record from the current input file and, if appropriate, *var* shall be considered a numeric string (see Expressions in awk, on page 2485). This form of **getline** shall set the **FNR** and **NR** variables.

getline [*var*] < *expression*
Read the next record of input from a named file. The *expression* shall be evaluated to produce a string that is used as a pathname. If the file of that name is not currently open, it shall be opened. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall read subsequent records from the file. The file shall remain open until the **close** function is called with an expression that evaluates to the same string value. If *var* is omitted, $0 and **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered a numeric string (see Expressions in awk, on page 2485).

The **getline** operator can form ambiguous constructs when there are unparenthesized binary operators (including concatenate) to the right of the `'<'` (up to the end of the expression containing the **getline**). The result of evaluating such a construct is unspecified, and conforming applications shall parenthesize properly all such usages.

system(*expression*)
Execute the command given by *expression* in a manner equivalent to the *system*() function defined in the System Interfaces volume of POSIX.1-2017 and return the exit status of the command.

All forms of **getline** shall return 1 for successful input, zero for end-of-file, and –1 for an error.

Where strings are used as the name of a file or pipeline, the application shall ensure that the strings are textually identical. The terminology ``same string value'' implies that ``equivalent strings'', even those that differ only by <space> characters, represent different files.

User-Defined Functions

The *awk* language also provides user-defined functions. Such functions can be defined as:

```
function name([parameter, ...]) { statements }
```

A function can be referred to anywhere in an *awk* program; in particular, its use can precede its definition. The scope of a function is global.

Function parameters, if present, can be either scalars or arrays; the behavior is undefined if an array name is passed as a parameter that the function uses as a scalar, or if a scalar expression is passed as a parameter that the function uses as an array. Function parameters shall be passed by value if scalar and by reference if array name.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars shall evaluate to the uninitialized value until they are otherwise initialized, and the extra parameters that are used in the function body as arrays shall be treated as uninitialized arrays where each element evaluates to the uninitialized value until otherwise initialized.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function's parameters shall be unchanged, except for array parameters passed by reference. The

return statement can be used to return a value. If a **return** statement appears outside of a function definition, the behavior is undefined.

In the function definition, <newline> characters shall be optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a *pattern-action* pair is allowed.

Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for *awk* programs. The general conventions for this style of grammar are described in Section 1.3 (on page 2335). A valid program can be represented as the non-terminal symbol *program* in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

This grammar has several ambiguities that shall be resolved as follows:

Operator precedence and associativity shall be as described in Table 4-1 (on page 2485).

In case of ambiguity, an **else** shall be associated with the most immediately preceding **if** that would satisfy the grammar.

In some contexts, a <slash> (`'/'`) that is used to surround an ERE could also be the division operator. This shall be resolved in such a way that wherever the division operator could appear, a <slash> is assumed to be the division operator. (There is no unary division operator.)

Each expression in an *awk* program shall conform to the precedence and associativity rules, even when this is not needed to resolve an ambiguity. For example, because `'$'` has higher precedence than `'++'`, the string `"$x++--"` is not a valid *awk* expression, even though it is unambiguously parsed by the grammar as `"$(x++)--"`.

One convention that might not be obvious from the formal grammar is where <newline> characters are acceptable. There are several obvious placements such as terminating a statement, and a <backslash> can be used to escape <newline> characters between any lexical tokens. In addition, <newline> characters without <backslash> characters can follow a comma, an open brace, logical AND operator (`"&&"`), logical OR operator (`"||"`), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print  $1,
         $2 }
```

Lexical Conventions

The lexical conventions for *awk* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *awk* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the <number-sign> character and terminated by, but excluding the next occurrence of, a <newline>. Comments shall have no effect, except to delimit lexical tokens.
3. The <newline> shall be recognized as the token **NEWLINE**.
4. A <backslash> character immediately followed by a <newline> shall have no effect.
5. The token **STRING** shall represent a string constant. A string constant shall begin with the character `'"'`. Within a string constant, a <backslash> character shall be considered to begin an escape sequence as specified in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in Table 4-2 (on page 2492) shall be recognized. A <newline> shall not occur within a string constant. A string constant shall be terminated by the first unescaped occurrence of

80803 the character `'"'` after the one that begins the string constant. The value of the string
80804 shall be the sequence of all unescaped characters and values of escape sequences
80805 between, but not including, the two delimiting `'"'` characters.

80806 6. The token **ERE** represents an extended regular expression constant. An ERE constant
80807 shall begin with the <slash> character. Within an ERE constant, a <backslash> character
80808 shall be considered to begin an escape sequence as specified in the table in XBD Chapter 5
80809 (on page 121). In addition, the escape sequences in Table 4-2 (on page 2492) shall be
80810 recognized. The application shall ensure that a <newline> does not occur within an ERE
80811 constant. An ERE constant shall be terminated by the first unescaped occurrence of the
80812 <slash> character after the one that begins the ERE constant. The extended regular
80813 expression represented by the ERE constant shall be the sequence of all unescaped
80814 characters and values of escape sequences between, but not including, the two delimiting
80815 <slash> characters.

80816 7. A <blank> shall have no effect, except to delimit lexical tokens or within **STRING** or **ERE**
80817 tokens.

80818 8. The token **NUMBER** shall represent a numeric constant. Its form and numeric value shall
80819 either be equivalent to the **decimal-floating-constant** token as specified by the ISO C
80820 standard, or it shall be a sequence of decimal digits and shall be evaluated as an integer
80821 constant in decimal. In addition, implementations may accept numeric constants with the
80822 form and numeric value equivalent to the **hexadecimal-constant** and **hexadecimal-**
80823 **floating-constant** tokens as specified by the ISO C standard.

80824 If the value is too large or too small to be representable (see Section 1.1.2, on page 2331),
80825 the behavior is undefined.

80826 9. A sequence of underscores, digits, and alphabetics from the portable character set (see
80827 XBD Section 6.1, on page 125), beginning with an <underscore> or alphabetic character,
80828 shall be considered a word.

80829 10. The following words are keywords that shall be recognized as individual tokens; the
80830 name of the token is the same as the keyword:

80831	**BEGIN**	**delete**	**END**	**function**	**in**	**printf**
80832	**break**	**do**	**exit**	**getline**	**next**	**return**
80833	**continue**	**else**	**for**	**if**	**print**	**while**

80834 11. The following words are names of built-in functions and shall be recognized as the token
80835 **BUILTIN_FUNC_NAME**:

80836	**atan2**	**gsub**	**log**	**split**	**sub**	**toupper**
80837	**close**	**index**	**match**	**sprintf**	**substr**	
80838	**cos**	**int**	**rand**	**sqrt**	**system**	
80839	**exp**	**length**	**sin**	**srand**	**tolower**	

80840 The above-listed keywords and names of built-in functions are considered reserved
80841 words.

80842 12. The token **NAME** shall consist of a word that is not a keyword or a name of a built-in
80843 function and is not followed immediately (without any delimiters) by the `'('` character.

80844 13. The token **FUNC_NAME** shall consist of a word that is not a keyword or a name of a
80845 built-in function, followed immediately (without any delimiters) by the `'('` character.
80846 The `'('` character shall not be included as part of the token.

14. The following two-character sequences shall be recognized as the named tokens:

Token Name	Sequence	Token Name	Sequence
ADD_ASSIGN	+=	**NO_MATCH**	!~
SUB_ASSIGN	−=	**EQ**	==
MUL_ASSIGN	*=	**LE**	<=
DIV_ASSIGN	/=	**GE**	>=
MOD_ASSIGN	%=	**NE**	!=
POW_ASSIGN	^=	**INCR**	++
OR	||	**DECR**	−−
AND	&&	**APPEND**	>>

15. The following single characters shall be recognized as tokens whose names are the character:

```
<newline> { } ( ) [ ] , ; + − * % ^ ! > < | ? : ~ $ =
```

There is a lexical ambiguity between the token **ERE** and the tokens `'/'` and **DIV_ASSIGN**. When an input sequence begins with a <slash> character in any syntactic context where the token `'/'` or **DIV_ASSIGN** could appear as the next token in a valid program, the longer of those two tokens that can be recognized shall be recognized. In any other syntactic context where the token **ERE** could appear as the next token in a valid program, the token **ERE** shall be recognized.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 An error occurred.

The exit status can be altered within the program by using an **exit** expression.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *awk* shall write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *progfile* operand is not a valid *awk* program (as specified in the EXTENDED DESCRIPTION section), the behavior is undefined.

APPLICATION USAGE

The **index**, **length**, **match**, and **substr** functions should not be confused with similar functions in the ISO C standard; the *awk* versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

When using *awk* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

On implementations where the `"=="` operator checks if strings collate equally, applications needing to check whether strings are identical can use:

```
length(a) == length(b) && index(a,b) == 1
```

On implementations where the "==" operator checks if strings are identical, applications needing to check whether strings collate equally can use:

```
a <= b && a >= b
```

EXAMPLES

The *awk* program specified in the command line is most easily specified within single-quotes (for example, *'program'*) for applications using *sh*, because *awk* programs commonly contain characters that are special to the shell, including double-quotes. In the cases where an *awk* program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/'\''/ { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with *quote*:.

The following are examples of simple *awk* programs:

1. Write to the standard output all input lines for which field 3 is greater than 5:

   ```
   $3 > 5
   ```

2. Write every tenth line:

   ```
   (NR % 10) == 0
   ```

3. Write any line with a substring matching the regular expression:

   ```
   /(G|D)(2[0–9][[:alpha:]]*)/
   ```

4. Print any line with a substring containing a 'G' or 'D', followed by a sequence of digits and characters. This example uses character classes **digit** and **alpha** to match language-independent digit and alphabetic characters respectively:

   ```
   /(G|D)([[:digit:][:alpha:]]*)/
   ```

5. Write any line in which the second field matches the regular expression and the fourth field does not:

   ```
   $2 ~ /xyz/ && $4 !~ /xyz/
   ```

6. Write any line in which the second field contains a <backslash>:

   ```
   $2 ~ /\\/
   ```

7. Write any line in which the second field contains a <backslash>. Note that <backslash>-escapes are interpreted twice; once in lexical processing of the string and once in processing the regular expression:

   ```
   $2 ~ "\\\\"
   ```

8. Write the second to the last and the last field in each line. Separate the fields by a <colon>:

   ```
   {OFS=":";print $(NF–1), $NF}
   ```

9. Write the line number and number of fields in each line. The three strings representing the line number, the <colon>, and the number of fields are concatenated and that string is written to standard output:

   ```
   {print NR ":" NF}
   ```

10. Write lines longer than 72 characters:

```
length($0) > 72
```

11. Write the first two fields in opposite order separated by **OFS**:

```
{ print $2, $1 }
```

12. Same, with input fields separated by a <comma> or <space> and <tab> characters, or both:

```
BEGIN { FS = ",[ \t]*|[ \t]+" }
      { print $2, $1 }
```

13. Add up the first column, print sum, and average:

```
      {s += $1 }
END   {print "sum is ", s, " average is", s/NR}
```

14. Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

15. Write all lines between occurrences of the strings **start** and **stop**:

```
/start/, /stop/
```

16. Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

17. Simulate *echo*:

```
BEGIN  {
        for (i = 1; i < ARGC; ++i)
        printf("%s%s", ARGV[i], i==ARGC-1?"\n":" ")
}
```

18. Write the path prefixes contained in the *PATH* environment variable, one per line:

```
BEGIN  {
        n = split (ENVIRON["PATH"], path, ":")
        for (i = 1; i <= n; ++i)
        print path[i]
}
```

19. If there is a file named **input** containing page headers of the form:

    Page #

    and a file named **program** that contains:

```
/Page/   { $2 = n++; }
         { print }
```

    then the command line:

```
awk -f program n=5 input
```

    prints the file **input**, filling in page numbers starting at 5.

RATIONALE

This description is based on the new *awk*, ``nawk'', (see the referenced *The AWK Programming Language*), which introduced a number of new features to the historical *awk*:

1. New keywords: **delete**, **do**, **function**, **return**
2. New built-in functions: **atan2**, **close**, **cos**, **gsub**, **match**, **rand**, **sin**, **srand**, **sub**, **system**
3. New predefined variables: **FNR**, **ARGC**, **ARGV**, **RSTART**, **RLENGTH**, **SUBSEP**
4. New expression operators: **?**, **:**, **,**, **^**
5. The **FS** variable and the third argument to **split**, now treated as extended regular expressions.
6. The operator precedence, changed to more closely match the C language. Two examples of code that operate differently are:

```
while ( n /= 10 > 1) ...
if (!"wk" ~ /bwk/) ...
```

Several features have been added based on newer implementations of *awk*:

Multiple instances of **−f** *progfile* are permitted.

The new option **−v** *assignment*.

The new predefined variable **ENVIRON**.

New built-in functions **toupper** and **tolower**.

More formatting capabilities are added to **printf** to match the ISO C standard.

Earlier versions of this standard required implementations to support multiple adjacent <semicolon>s, lines with one or more <semicolon> before a rule (*pattern-action* pairs), and lines with only <semicolon>(s). These are not required by this standard and are considered poor programming practice, but can be accepted by an implementation of *awk* as an extension.

The overall *awk* syntax has always been based on the C language, with a few features from the shell command language and other sources. Because of this, it is not completely compatible with any other language, which has caused confusion for some users. It is not the intent of the standard developers to address such issues. A few relatively minor changes toward making the language more compatible with the ISO C standard were made; most of these changes are based on similar changes in recent implementations, as described above. There remain several C-language conventions that are not in *awk*. One of the notable ones is the <comma> operator, which is commonly used to specify multiple expressions in the C language **for** statement. Also, there are various places where *awk* is more restrictive than the C language regarding the type of expression that can be used in a given context. These limitations are due to the different features that the *awk* language does provide.

Regular expressions in *awk* have been extended somewhat from historical implementations to make them a pure superset of extended regular expressions, as defined by POSIX.1-2017 (see XBD Section 9.4, on page 188). The main extensions are internationalization features and interval expressions. Historical implementations of *awk* have long supported <backslash>-escape sequences as an extension to extended regular expressions, and this extension has been retained despite inconsistency with other utilities. The number of escape sequences recognized in both extended regular expressions and strings has varied (generally increasing with time) among implementations. The set specified by POSIX.1-2017 includes most sequences known to be supported by popular implementations and by the ISO C standard. One sequence that is not supported is hexadecimal value escapes beginning with `'\x'`. This would

allow values expressed in more than 9 bits to be used within *awk* as in the ISO C standard. However, because this syntax has a non-deterministic length, it does not permit the subsequent character to be a hexadecimal digit. This limitation can be dealt with in the C language by the use of lexical string concatenation. In the *awk* language, concatenation could also be a solution for strings, but not for extended regular expressions (either lexical ERE tokens or strings used dynamically as regular expressions). Because of this limitation, the feature has not been added to POSIX.1-2017.

When a string variable is used in a context where an extended regular expression normally appears (where the lexical token ERE is used in the grammar) the string does not contain the literal <slash> characters.

Some versions of *awk* allow the form:

```
func name(args, ... ) { statements }
```

This has been deprecated by the authors of the language, who asked that it not be specified.

Historical implementations of *awk* produce an error if a **next** statement is executed in a **BEGIN** action, and cause *awk* to terminate if a **next** statement is executed in an **END** action. This behavior has not been documented, and it was not believed that it was necessary to standardize it.

The specification of conversions between string and numeric values is much more detailed than in the documentation of historical implementations or in the referenced *The AWK Programming Language*. Although most of the behavior is designed to be intuitive, the details are necessary to ensure compatible behavior from different implementations. This is especially important in relational expressions since the types of the operands determine whether a string or numeric comparison is performed. From the perspective of an application developer, it is usually sufficient to expect intuitive behavior and to force conversions (by adding zero or concatenating a null string) when the type of an expression does not obviously match what is needed. The intent has been to specify historical practice in almost all cases. The one exception is that, in historical implementations, variables and constants maintain both string and numeric values after their original value is converted by any use. This means that referencing a variable or constant can have unexpected side-effects. For example, with historical implementations the following program:

```
{
    a = "+2"
    b = 2
    if (NR % 2)
        c = a + b
    if (a == b)
        print "numeric comparison"
    else
        print "string comparison"
}
```

would perform a numeric comparison (and output numeric comparison) for each odd-numbered line, but perform a string comparison (and output string comparison) for each even-numbered line. POSIX.1-2017 ensures that comparisons will be numeric if necessary. With historical implementations, the following program:

```
BEGIN {
    OFMT = "%e"
    print 3.14
```

```
        OFMT = "%f"
        print 3.14
    }
```

would output `"3.140000e+00"` twice, because in the second **print** statement the constant `"3.14"` would have a string value from the previous conversion. POSIX.1-2017 requires that the output of the second **print** statement be `"3.140000"`. The behavior of historical implementations was seen as too unintuitive and unpredictable.

It was pointed out that with the rules contained in early drafts, the following script would print nothing:

```
BEGIN {
    y[1.5] = 1
    OFMT = "%e"
    print y[1.5]
}
```

Therefore, a new variable, **CONVFMT**, was introduced. The **OFMT** variable is now restricted to affecting output conversions of numbers to strings and **CONVFMT** is used for internal conversions, such as comparisons or array indexing. The default value is the same as that for **OFMT**, so unless a program changes **CONVFMT** (which no historical program would do), it will receive the historical behavior associated with internal string conversions.

The POSIX *awk* lexical and syntactic conventions are specified more formally than in other sources. Again the intent has been to specify historical practice. One convention that may not be obvious from the formal grammar as in other verbal descriptions is where <newline> characters are acceptable. There are several obvious placements such as terminating a statement, and a <backslash> can be used to escape <newline> characters between any lexical tokens. In addition, <newline> characters without <backslash> characters can follow a comma, an open brace, a logical AND operator (`"&&"`), a logical OR operator (`"||"`), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print $1,
        $2 }
```

The requirement that *awk* add a trailing <newline> to the program argument text is to simplify the grammar, making it match a text file in form. There is no way for an application or test suite to determine whether a literal <newline> is added or whether *awk* simply acts as if it did.

POSIX.1-2017 requires several changes from historical implementations in order to support internationalization. Probably the most subtle of these is the use of the decimal-point character, defined by the *LC_NUMERIC* category of the locale, in representations of floating-point numbers. This locale-specific character is used in recognizing numeric input, in converting between strings and numeric values, and in formatting output. However, regardless of locale, the <period> character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments). This is essentially the same convention as the one used in the ISO C standard. The difference is that the C language includes the *setlocale*() function, which permits an application to modify its locale. Because of this capability, a C application begins executing with its locale set to the C locale, and only executes in the environment-specified locale after an explicit call to *setlocale*(). However, adding such an elaborate new feature to the *awk* language was seen as inappropriate for POSIX.1-2017. It is possible to execute an *awk* program explicitly in any desired locale by setting the environment in the shell.

The undefined behavior resulting from NULs in extended regular expressions allows future

extensions for the GNU *gawk* program to process binary data.

The behavior in the case of invalid *awk* programs (including lexical, syntactic, and semantic errors) is undefined because it was considered overly limiting on implementations to specify. In most cases such errors can be expected to produce a diagnostic and a non-zero exit status. However, some implementations may choose to extend the language in ways that make use of certain invalid constructs. Other invalid constructs might be deemed worthy of a warning, but otherwise cause some reasonable behavior. Still other constructs may be very difficult to detect in some implementations. Also, different implementations might detect a given error during an initial parsing of the program (before reading any input files) while others might detect it when executing the program after reading some input. Implementors should be aware that diagnosing errors as early as possible and producing useful diagnostics can ease debugging of applications, and thus make an implementation more usable.

The unspecified behavior from using multi-character **RS** values is to allow possible future extensions based on extended regular expressions used for record separators. Historical implementations take the first character of the string and ignore the others.

Unspecified behavior when *split*(*string*,*array*,<null>) is used is to allow a proposed future extension that would split up a string into an array of individual characters.

In the context of the **getline** function, equally good arguments for different precedences of the **|** and **<** operators can be made. Historical practice has been that:

```
getline < "a" "b"
```

is parsed as:

```
( getline < "a" ) "b"
```

although many would argue that the intent was that the file **ab** should be read. However:

```
getline < "x" + 1
```

parses as:

```
getline < ( "x" + 1 )
```

Similar problems occur with the **|** version of **getline**, particularly in combination with **$**. For example:

```
$"echo hi" | getline
```

(This situation is particularly problematic when used in a **print** statement, where the **|getline** part might be a redirection of the **print**.)

Since in most cases such constructs are not (or at least should not) be used (because they have a natural ambiguity for which there is no conventional parsing), the meaning of these constructs has been made explicitly unspecified. (The effect is that a conforming application that runs into the problem must parenthesize to resolve the ambiguity.) There appeared to be few if any actual uses of such constructs.

Grammars can be written that would cause an error under these circumstances. Where backwards-compatibility is not a large consideration, implementors may wish to use such grammars.

Some historical implementations have allowed some built-in functions to be called without an argument list, the result being a default argument list chosen in some ``reasonable'' way. Use of **length** as a synonym for **length($0)** is the only one of these forms that is thought to be widely known or widely used; this particular form is documented in various places (for example, most

historical *awk* reference pages, although not in the referenced *The AWK Programming Language*) as legitimate practice. With this exception, default argument lists have always been undocumented and vaguely defined, and it is not at all clear how (or if) they should be generalized to user-defined functions. They add no useful functionality and preclude possible future extensions that might need to name functions without calling them. Not standardizing them seems the simplest course. The standard developers considered that **length** merited special treatment, however, since it has been documented in the past and sees possibly substantial use in historical programs. Accordingly, this usage has been made legitimate, but Issue 5 removed the obsolescent marking for XSI-conforming implementations and many otherwise conforming applications depend on this feature.

In **sub** and **gsub**, if *repl* is a string literal (the lexical token **STRING**), then two consecutive <backslash> characters should be used in the string to ensure a single <backslash> will precede the <ampersand> when the resultant string is passed to the function. (For example, to specify one literal <ampersand> in the replacement string, use **gsub**(**ERE**, `"\\&"`).)

Historically, the only special character in the *repl* argument of **sub** and **gsub** string functions was the <ampersand> (`'&'`) character and preceding it with the <backslash> character was used to turn off its special meaning.

The description in the ISO POSIX-2: 1993 standard introduced behavior such that the <backslash> character was another special character and it was unspecified whether there were any other special characters. This description introduced several portability problems, some of which are described below, and so it has been replaced with the more historical description. Some of the problems include:

> Historically, to create the replacement string, a script could use **gsub**(**ERE**, `"\\&"`), but with the ISO POSIX-2: 1993 standard wording, it was necessary to use **gsub**(**ERE**, `"\\\\&"`). The <backslash> characters are doubled here because all string literals are subject to lexical analysis, which would reduce each pair of <backslash> characters to a single <backslash> before being passed to **gsub**.
>
> Since it was unspecified what the special characters were, for portable scripts to guarantee that characters are printed literally, each character had to be preceded with a <backslash>. (For example, a portable script had to use **gsub**(**ERE**, `"\\h\\i"`) to produce a replacement string of `"hi"`.)

The description for comparisons in the ISO POSIX-2: 1993 standard did not properly describe historical practice because of the way numeric strings are compared as numbers. The current rules cause the following code:

```
if (0 == "000")
    print "strange, but true"
else
    print "not true"
```

to do a numeric comparison, causing the **if** to succeed. It should be intuitively obvious that this is incorrect behavior, and indeed, no historical implementation of *awk* actually behaves this way.

To fix this problem, the definition of *numeric string* was enhanced to include only those values obtained from specific circumstances (mostly external sources) where it is not possible to determine unambiguously whether the value is intended to be a string or a numeric.

Variables that are assigned to a numeric string shall also be treated as a numeric string. (For example, the notion of a numeric string can be propagated across assignments.) In comparisons, all variables having the uninitialized value are to be treated as a numeric operand evaluating to the numeric value zero.

Uninitialized variables include all types of variables including scalars, array elements, and fields. The definition of an uninitialized value in Variables and Special Variables (on page 2489) is necessary to describe the value placed on uninitialized variables and on fields that are valid (for example, **< $NF**) but have no characters in them and to describe how these variables are to be used in comparisons. A valid field, such as **$1**, that has no characters in it can be obtained from an input line of `"\t\t"` when **FS=**`'\t'`. Historically, the comparison (**$1<**10) was done numerically after evaluating **$1** to the value zero.

The phrase ``... also shall have the numeric value of the numeric string'' was removed from several sections of the ISO POSIX-2: 1993 standard because is specifies an unnecessary implementation detail. It is not necessary for POSIX.1-2017 to specify that these objects be assigned two different values. It is only necessary to specify that these objects may evaluate to two different values depending on context.

Historical implementations of *awk* did not parse hexadecimal integer or floating constants like `"0xa"` and `"0xap0"`. Due to an oversight, the 2001 through 2004 editions of this standard required support for hexadecimal floating constants. This was due to the reference to *atof*( ). This version of the standard allows but does not require implementations to use *atof*( ) and includes a description of how floating-point numbers are recognized as an alternative to match historic behavior. The intent of this change is to allow implementations to recognize floating-point constants according to either the ISO/IEC 9899: 1990 standard or ISO/IEC 9899: 1999 standard, and to allow (but not require) implementations to recognize hexadecimal integer constants.

Historical implementations of *awk* did not support floating-point infinities and NaNs in *numeric strings*; e.g., `"-INF"` and `"NaN"`. However, implementations that use the *atof*( ) or *strtod*( ) functions to do the conversion picked up support for these values if they used a ISO/IEC 9899: 1999 standard version of the function instead of a ISO/IEC 9899: 1990 standard version. Due to an oversight, the 2001 through 2004 editions of this standard did not allow support for infinities and NaNs, but in this revision support is allowed (but not required). This is a silent change to the behavior of *awk* programs; for example, in the POSIX locale the expression:

```
("-INF" + 0 < 0)
```

formerly had the value 0 because `"-INF"` converted to 0, but now it may have the value 0 or 1.

FUTURE DIRECTIONS

A future version of this standard may require the `"!="` and `"=="` operators to perform string comparisons by checking if the strings are identical (and not by checking if they collate equally).

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The *awk* utility is aligned with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE PASC Interpretation 1003.2 #211 is applied, adding the sentence ``An occurrence of two consecutive <backslash> characters shall be interpreted as just a single literal <backslash> character.'' into the description of the **sub** string function.

Issue 7

PASC Interpretation 1003.2-1992 #107 (SD5-XCU-ERN-73) is applied, updating the description of the **OFS** variable.

Austin Group Interpretation 1003.1-2001 #189 is applied.

Austin Group Interpretation 1003.1-2001 #201 is applied, permitting implementations to support infinities and NaNs.

SD5-XCU-ERN-79 is applied, restoring the horizontal lines to Table 4-1 (on page 2485), and SD5-XCU-ERN-80 is applied, changing the order of some table entries.

SD5-XCU-ERN-87 is applied, updating the descriptive text of the Grammar.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The EXTENDED DESCRIPTION is changed to make the support of hexadecimal integer and floating constants optional.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0057 [224], XCU/TC1-2008/0058 [454], XCU/TC1-2008/0059 [224], XCU/TC1-2008/0060 [224], XCU/TC1-2008/0061 [254], XCU/TC1-2008/0062 [254], XCU/TC1-2008/0063 [224], and XCU/TC1-2008/0064 [454] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0058 [584], XCU/TC2-2008/0059 [963], XCU/TC2-2008/0060 [226], XCU/TC2-2008/0061 [663], XCU/TC2-2008/0062 [963], XCU/TC2-2008/0063 [226], and XCU/TC2-2008/0064 [963] are applied.

NAME

basename — return non-directory portion of a pathname

SYNOPSIS

```
basename string [suffix]
```

DESCRIPTION

The *string* operand shall be treated as a pathname, as defined in XBD Section 3.271 (on page 76). The string *string* shall be converted to the filename corresponding to the last pathname component in *string* and then the suffix string *suffix*, if present, shall be removed. This shall be done by performing actions equivalent to the following steps in order:

1. If *string* is a null string, it is unspecified whether the resulting string is `'.'` or a null string. In either case, skip steps 2 through 6.
2. If *string* is `"//"`, it is implementation-defined whether steps 3 to 6 are skipped or processed.
3. If *string* consists entirely of <slash> characters, *string* shall be set to a single <slash> character. In this case, skip steps 4 to 6.
4. If there are any trailing <slash> characters in *string*, they shall be removed.
5. If there are any <slash> characters remaining in *string*, the prefix of *string* up to and including the last <slash> character in *string* shall be removed.
6. If the *suffix* operand is present, is not identical to the characters remaining in *string*, and is identical to a suffix of the characters remaining in *string*, the suffix *suffix* shall be removed from *string*. Otherwise, *string* is not modified by this step. It shall not be considered an error if *suffix* is not found in *string*.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

string A string.

suffix A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *basename*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The *basename* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The definition of *pathname* specifies implementation-defined behavior for pathnames starting with two <slash> characters. Therefore, applications shall not arbitrarily add <slash> characters to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES
If the string *string* is a valid pathname:

```
$(basename -- "string")
```

produces a filename that could be used to open the file named by *string* in the directory returned by:

```
$(dirname -- "string")
```

If the string *string* is not a valid pathname, the same algorithm is used, but the result need not be a valid filename. The *basename* utility is not expected to make any judgements about the validity of *string* as a pathname; it just follows the specified algorithm to produce a result string.

The following shell script compiles **/usr/src/cmd/cat.c** and moves the output to a file named **cat** in the current directory when invoked with the argument **/usr/src/cmd/cat** or with the argument **/usr/src/cmd/cat.c**:

```
c99 -- "$(dirname -- "$1")/$(basename -- "$1" .c).c" &&
mv a.out "$(basename -- "$1" .c)"
```

The EXAMPLES section of the *basename*() function (see XSH *basename*()) includes a table showing examples of the results of processing several sample pathnames by the *basename*() and

dirname( ) functions and by the *basename* and *dirname* utilities.

RATIONALE

The behaviors of *basename* and *dirname* have been coordinated so that when *string* is a valid pathname:

```
$(basename -- "string")
```

would be a valid filename for the file in the directory:

```
$(dirname -- "string")
```

This would not work for the early proposal versions of these utilities due to the way it specified handling of trailing <slash> characters.

Since the definition of *pathname* specifies implementation-defined behavior for pathnames starting with two <slash> characters, this volume of POSIX.1-2017 specifies similar implementation-defined behavior for the *basename* and *dirname* utilities.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

IEEE PASC Interpretation 1003.2 #164 is applied.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0065 [192,538], XCU/TC1-2008/0066 [192,538], and XCU/TC1-2008/0067 [192,430,538] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0065 [612] is applied.

NAME

batch ‡'schedule commands to be executed in a batch queue

SYNOPSIS

```
batch
```

DESCRIPTION

The *batch* utility shall read commands from standard input and schedule them for execution in a batch queue. It shall be the equivalent of the command:

```
at −q b −m now
```

where queue *b* is a special *at* queue, specifically for batch jobs. Batch jobs shall be submitted to the batch queue with no time constraints and shall be run by the system using algorithms, based on unspecified factors, that may vary with each invocation of *batch*.

XSI Users shall be permitted to use *batch* if their name appears in the file **at.allow** which is located in an implementation-defined directory. If that file does not exist, the file **at.deny**, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to *batch*. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only **at.deny** exists and is empty, global usage shall be permitted. The **at.allow** and **at.deny** files shall consist of one user name per line.

OPTIONS

None.

OPERANDS

None.

STDIN

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 2345).

INPUT FILES

XSI The text files **at.allow** and **at.deny**, which are located in an implementation-defined directory, shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the *at* and *batch* utilities.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *batch*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LC_TIME Determine the format and contents for date and time strings written by *batch*.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

SHELL Determine the name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, *sh* shall be used. If it is set to a value other than a name for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use the login shell from the user database; any of the preceding accompanied by a warning diagnostic about which was chosen.

TZ Determine the timezone. The job shall be submitted for execution at the time specified by *timespec* or **−t** *time* relative to the timezone specified by the *TZ* variable. If *timespec* specifies a timezone, it overrides *TZ*. If *timespec* does not specify a timezone and *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

STDERR

The following shall be written to standard error when a job has been successfully submitted:

```
"job %s at %s\n", at_job_id, <date>
```

where *date* shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the *TZ* variable).

Neither this, nor warning messages concerning the selection of the command interpreter, are considered a diagnostic that changes the exit status.

Diagnostic messages, if any, shall be written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The job shall not be scheduled.

APPLICATION USAGE

It may be useful to redirect standard output within the specified commands.

EXAMPLES

1. This sequence can be used at a terminal:

```
batch
sort < file >outfile
EOT
```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
batch <<!
diff file1 file2 2>&1 >outfile | mailx mygroup
!
```

RATIONALE

Early proposals described *batch* in a manner totally separated from *at*, even though the historical model treated it almost as a synonym for *at* **−qb**. A number of features were added to list and control batch work separately from those in *at*. Upon further reflection, it was decided that the benefit of this did not merit the change to the historical interface.

The **−m** option was included on the equivalent *at* command because it is historical practice to mail results to the submitter, even if all job-produced output is redirected. As explained in the RATIONALE for *at*, the **now** keyword submits the job for immediate execution (after scheduling delays), despite some historical systems where *at* **now** would have been considered an error.

FUTURE DIRECTIONS

None.

SEE ALSO

at

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The NAME is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

The *batch* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the *batch* utility.

NAME

bc — arbitrary-precision arithmetic language

SYNOPSIS

```
bc [-l] [file...]
```

DESCRIPTION

The *bc* utility shall implement an arbitrary precision calculator. It shall take input from any files given, then read from the standard input. If the standard input and standard output to *bc* are attached to a terminal, the invocation of *bc* shall be considered to be *interactive*, causing behavioral constraints described in the following sections.

OPTIONS

The *bc* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-l (The letter ell.) Define the math functions and initialize *scale* to 20, instead of the default zero; see the EXTENDED DESCRIPTION section.

OPERANDS

The following operand shall be supported:

file A pathname of a text file containing *bc* program statements. After all *file*s have been read, *bc* shall read the standard input.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files containing a sequence of comments, statements, and function definitions that shall be executed as they are read.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *bc*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output of the *bc* utility shall be controlled by the program read, and consist of zero or more lines containing the value of all executed expressions without assignments. The radix and precision of the output shall be controlled by the values of the **obase** and **scale** variables; see the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for *bc* programs. The general conventions for this style of grammar are described in Section 1.3 (on page 2335). A valid program can be represented as the non-terminal symbol **program** in the grammar. This formal syntax shall take precedence over the text syntax description.

                        ;
```

Lexical Conventions in bc

The lexical conventions for *bc* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *bc* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the two adjacent characters `"/*"` and terminated by the next occurrence of the two adjacent characters `"*/"`. Comments shall have no effect except to delimit lexical tokens.
3. The <newline> shall be recognized as the token **NEWLINE**.
4. The token **STRING** shall represent a string constant; it shall consist of any characters beginning with the double-quote character (`'"'`) and terminated by another occurrence of the double-quote character. The value of the string is the sequence of all characters between, but not including, the two double-quote characters. All characters shall be taken literally from the input, and there is no way to specify a string containing a double-quote character. The length of the value of each string shall be limited to {BC_STRING_MAX} bytes.
5. A <blank> shall have no effect except as an ordinary character if it appears within a **STRING** token, or to delimit a lexical token other than **STRING**.
6. The combination of a <backslash> character immediately followed by a <newline> shall have no effect other than to delimit lexical tokens with the following exceptions:

81664 It shall be interpreted as the character sequence "\<newline>" in **STRING** tokens.

81665 It shall be ignored as part of a multi-line **NUMBER** token.

81666 7. The token **NUMBER** shall represent a numeric constant. It shall be recognized by the
81667 following grammar:

```
81668 NUMBER  : integer
81669         | '.' integer
81670         | integer '.'
81671         | integer '.' integer
81672         ;

81673 integer : digit
81674         | integer digit
81675         ;

81676 digit   : 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7
81677         | 8 | 9 | A | B | C | D | E | F
81678         ;
```

81679 8. The value of a **NUMBER** token shall be interpreted as a numeral in the base specified by
81680 the value of the internal register **ibase** (described below). Each of the **digit** characters
81681 shall have the value from 0 to 15 in the order listed here, and the <period> character shall
81682 represent the radix point. The behavior is undefined if digits greater than or equal to the
81683 value of **ibase** appear in the token. However, note the exception for single-digit values
81684 being assigned to **ibase** and **obase** themselves, in Operations in bc (on page 2529).

81685 9. The following keywords shall be recognized as tokens:

auto	**ibase**	**length**	**return**	**while**
break	**if**	**obase**	**scale**	
define	**for**	**quit**	**sqrt**	

81689 10. Any of the following characters occurring anywhere except within a keyword shall be
81690 recognized as the token **LETTER**:

81691 `a b c d e f g h i j k l m n o p q r s t u v w x y z`

81692 11. The following single-character and two-character sequences shall be recognized as the
81693 token **ASSIGN_OP**:

81694 `= += -= *= /= %= ^=`

81695 12. If an '=' character, as the beginning of a token, is followed by a '-' character with no
81696 intervening delimiter, the behavior is undefined.

81697 13. The following single-characters shall be recognized as the token **MUL_OP**:

81698 `* / %`

81699 14. The following single-character and two-character sequences shall be recognized as the
81700 token **REL_OP**:

81701 `== <= >= != < >`

81702 15. The following two-character sequences shall be recognized as the token **INCR_DECR**:

81703 `++ --`

16. The following single characters shall be recognized as tokens whose names are the character:

    `<newline> ( ) , + - ; [ ] ^ { }`

17. The token **EOF** is returned when the end of input is reached.

Operations in bc

There are three kinds of identifiers: ordinary identifiers, array identifiers, and function identifiers. All three types consist of single lowercase letters. Array identifiers shall be followed by square brackets (`"[]"`). An array subscript is required except in an argument or auto list. Arrays are singly dimensioned and can contain up to {BC_DIM_MAX} elements. Indexing shall begin at zero so an array is indexed from 0 to {BC_DIM_MAX}−1. Subscripts shall be truncated to integers. The application shall ensure that function identifiers are followed by parentheses, possibly enclosing arguments. The three types of identifiers do not conflict.

The following table summarizes the rules for precedence and associativity of all operators. Operators on the same line shall have the same precedence; rows are in order of decreasing precedence.

Table 4-3 Operators in *bc*

Operator	Associativity
`++, --`	N/A
`unary -`	N/A
`^`	Right to left
`*, /, %`	Left to right
`+, binary -`	Left to right
`=, +=, -=, *=, /=, %=, ^=`	Right to left
`==, <=, >=, !=, <, >`	None

Each expression or named expression has a *scale*, which is the number of decimal digits that shall be maintained as the fractional portion of the expression.

Named expressions are places where values are stored. Named expressions shall be valid on the left side of an assignment. The value of a named expression shall be the value stored in the place named. Simple identifiers and array elements are named expressions; they have an initial value of zero and an initial scale of zero.

The internal registers **scale**, **ibase**, and **obase** are all named expressions. The scale of an expression consisting of the name of one of these registers shall be zero; values assigned to any of these registers are truncated to integers. The **scale** register shall contain a global value used in computing the scale of expressions (as described below). The value of the register **scale** is limited to 0 ≤ **scale** ≤ {BC_SCALE_MAX} and shall have a default value of zero. The **ibase** and **obase** registers are the input and output number radix, respectively. The value of **ibase** shall be limited to:

`2 ≤ ibase ≤ 16`

The value of **obase** shall be limited to:

`2 ≤ obase ≤ {BC_BASE_MAX}`

When either **ibase** or **obase** is assigned a single **digit** value from the list in Lexical Conventions in bc (on page 2527), the value shall be assumed in hexadecimal. (For example, **ibase**=A sets to base ten, regardless of the current **ibase** value.) Otherwise, the behavior is undefined when

digits greater than or equal to the value of **ibase** appear in the input. Both **ibase** and **obase** shall have initial values of 10.

Internal computations shall be conducted as if in decimal, regardless of the input and output bases, to the specified number of decimal digits. When an exact result is not achieved (for example, **scale**=0; 3.2/1)**,** the result shall be truncated.

For all values of **obase** specified by this volume of POSIX.1-2017, *bc* shall output numeric values by performing each of the following steps in order:

1. If the value is less than zero, a <hyphen-minus> (`'-'`) character shall be output.
2. One of the following is output, depending on the numerical value:

   If the absolute value of the numerical value is greater than or equal to one, the integer portion of the value shall be output as a series of digits appropriate to **obase** (as described below), most significant digit first. The most significant non-zero digit shall be output next, followed by each successively less significant digit.

   If the absolute value of the numerical value is less than one but greater than zero and the scale of the numerical value is greater than zero, it is unspecified whether the character 0 is output.

   If the numerical value is zero, the character 0 shall be output.
3. If the scale of the value is greater than zero and the numeric value is not zero, a <period> character shall be output, followed by a series of digits appropriate to **obase** (as described below) representing the most significant portion of the fractional part of the value. If *s* represents the scale of the value being output, the number of digits output shall be *s* if **obase** is 10, less than or equal to *s* if **obase** is greater than 10, or greater than or equal to *s* if **obase** is less than 10. For **obase** values other than 10, this should be the number of digits needed to represent a precision of 10^s.

For **obase** values from 2 to 16, valid digits are the first **obase** of the single characters:

```
0 1 2 3 4 5 6 7 8 9 A B C D E F
```

which represent the values zero to 15, inclusive, respectively.

For bases greater than 16, each digit shall be written as a separate multi-digit decimal number. Each digit except the most significant fractional digit shall be preceded by a single <space>. For bases from 17 to 100, *bc* shall write two-digit decimal numbers; for bases from 101 to 1 000, three-digit decimal strings, and so on. For example, the decimal number 1 024 in base 25 would be written as:

```
Δ01Δ15Δ24
```

and in base 125, as:

```
Δ008Δ024
```

Very large numbers shall be split across lines with 70 characters per line in the POSIX locale; other locales may split at different character boundaries. Lines that are continued shall end with a <backslash>.

A function call shall consist of a function name followed by parentheses containing a <comma>-separated list of expressions, which are the function arguments. A whole array passed as an argument shall be specified by the array name followed by empty square brackets. All function arguments shall be passed by value. As a result, changes made to the formal parameters shall have no effect on the actual arguments. If the function terminates by executing

a **return** statement, the value of the function shall be the value of the expression in the parentheses of the **return** statement or shall be zero if no expression is provided or if there is no **return** statement.

The result of **sqrt**(*expression*) shall be the square root of the expression. The result shall be truncated in the least significant decimal place. The scale of the result shall be the scale of the expression or the value of **scale**, whichever is larger.

The result of **length**(*expression*) shall be the total number of significant decimal digits in the expression. The scale of the result shall be zero.

The result of **scale**(*expression*) shall be the scale of the expression. The scale of the result shall be zero.

A numeric constant shall be an expression. The scale shall be the number of digits that follow the radix point in the input representing the constant, or zero if no radix point appears.

The sequence (*expression*) shall be an expression with the same value and scale as *expression*. The parentheses can be used to alter the normal precedence.

The semantics of the unary and binary operators are as follows:

–expression
: The result shall be the negative of the *expression*. The scale of the result shall be the scale of *expression*.

The unary increment and decrement operators shall not modify the scale of the named expression upon which they operate. The scale of the result shall be the scale of that named expression.

++named-expression
: The named expression shall be incremented by one. The result shall be the value of the named expression after incrementing.

––named-expression
: The named expression shall be decremented by one. The result shall be the value of the named expression after decrementing.

named-expression++
: The named expression shall be incremented by one. The result shall be the value of the named expression before incrementing.

named-expression––
: The named expression shall be decremented by one. The result shall be the value of the named expression before decrementing.

The exponentiation operator, <circumflex> (`'^'`), shall bind right to left.

expression^expression
: The result shall be the first *expression* raised to the power of the second *expression*. If the second expression is not an integer, the behavior is undefined. If *a* is the scale of the left expression and *b* is the absolute value of the right expression, the scale of the result shall be:

```
if b >= 0 min(a * b, max(scale, a)) if b < 0 scale
```

The multiplicative operators (`'*'`, `'/'`, `'%'`) shall bind left to right.

*expression*expression*
: The result shall be the product of the two expressions. If *a* and *b* are the scales of the two expressions, then the scale of the result shall be:

```
min(a+b,max(scale,a,b))
```

expression/expression
The result shall be the quotient of the two expressions. The scale of the result shall be the value of **scale**.

expression%expression
For expressions *a* and *b*, *a%b* shall be evaluated equivalent to the steps:

1. Compute *a/b* to current scale.
2. Use the result to compute:

   ```
   a - (a / b) * b
   ```

   to scale:

   ```
   max(scale + scale(b), scale(a))
   ```

The scale of the result shall be:

```
max(scale + scale(b), scale(a))
```

When **scale** is zero, the `'%'` operator is the mathematical remainder operator.

The additive operators (`'+'`, `'-'`) shall bind left to right.

expression+expression
The result shall be the sum of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.

expression–expression
The result shall be the difference of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.

The assignment operators (`'='`, `"+="`, `"-="`, `"*="`, `"/="`, `"%="`, `"^="`) shall bind right to left.

named-expression=expression
This expression shall result in assigning the value of the expression on the right to the named expression on the left. The scale of both the named expression and the result shall be the scale of *expression*.

The compound assignment forms:

```
named-expression <operator>= expression
```

shall be equivalent to:

```
named-expression=named-expression <operator> expression
```

except that the *named-expression* shall be evaluated only once.

Unlike all other operators, the relational operators (`'<'`, `'>'`, `"<="`, `">="`, `"=="`, `"!="`) shall be only valid as the object of an **if**, **while**, or inside a **for** statement.

expression1<expression2
The relation shall be true if the value of *expression1* is strictly less than the value of *expression2*.

expression1>expression2
The relation shall be true if the value of *expression1* is strictly greater than the value of *expression2*.

81872 *expression1*<=*expression2*
81873 The relation shall be true if the value of *expression1* is less than or equal to the value of
81874 *expression2*.

81875 *expression1*>=*expression2*
81876 The relation shall be true if the value of *expression1* is greater than or equal to the value of
81877 *expression2*.

81878 *expression1*==*expression2*
81879 The relation shall be true if the values of *expression1* and *expression2* are equal.

81880 *expression1*!=*expression2*
81881 The relation shall be true if the values of *expression1* and *expression2* are unequal.

81882 There are only two storage classes in *bc*: global and automatic (local). Only identifiers that are
81883 local to a function need be declared with the **auto** command. The arguments to a function shall
81884 be local to the function. All other identifiers are assumed to be global and available to all
81885 functions. All identifiers, global and local, have initial values of zero. Identifiers declared as auto
81886 shall be allocated on entry to the function and released on returning from the function. They
81887 therefore do not retain values between function calls. Auto arrays shall be specified by the array
81888 name followed by empty square brackets. On entry to a function, the old values of the names
81889 that appear as parameters and as automatic variables shall be pushed onto a stack. Until the
81890 function returns, reference to these names shall refer only to the new values.

81891 References to any of these names from other functions that are called from this function also
81892 refer to the new value until one of those functions uses the same name for a local variable.

81893 When a statement is an expression, unless the main operator is an assignment, execution of the
81894 statement shall write the value of the expression followed by a <newline>.

81895 When a statement is a string, execution of the statement shall write the value of the string.

81896 Statements separated by <semicolon> or <newline> characters shall be executed sequentially. In
81897 an interactive invocation of *bc*, each time a <newline> is read that satisfies the grammatical
81898 production:

81899 `input_item : semicolon_list NEWLINE`

81900 the sequential list of statements making up the **semicolon_list** shall be executed immediately
81901 and any output produced by that execution shall be written without any delay due to buffering.

81902 In an **if** statement (**if**(*relation*) *statement*), the *statement* shall be executed if the relation is true.

81903 The **while** statement (**while**(*relation*) *statement*) implements a loop in which the *relation* is tested;
81904 each time the *relation* is true, the *statement* shall be executed and the *relation* retested. When the
81905 *relation* is false, execution shall resume after *statement*.

81906 A **for** statement(**for**(*expression*; *relation*; *expression*) *statement*) shall be the same as:

```
81907 first-expression
81908 while (relation) {
81909     statement
81910     last-expression
81911 }
```

81912 The application shall ensure that all three expressions are present.

81913 The **break** statement shall cause termination of a **for** or **while** statement.

81914 The **auto** statement (**auto** *identifier* **[**,*identifier***]** ...) shall cause the values of the identifiers to be

pushed down. The identifiers can be ordinary identifiers or array identifiers. Array identifiers shall be specified by following the array name by empty square brackets. The application shall ensure that the **auto** statement is the first statement in a function definition.

A **define** statement:

```
define LETTER ( opt_parameter_list ) {
    opt_auto_define_list
    statement_list
}
```

defines a function named **LETTER**. If a function named **LETTER** was previously defined, the **define** statement shall replace the previous definition. The expression:

```
LETTER ( opt_argument_list )
```

shall invoke the function named **LETTER**. The behavior is undefined if the number of arguments in the invocation does not match the number of parameters in the definition. Functions shall be defined before they are invoked. A function shall be considered to be defined within its own body, so recursive calls are valid. The values of numeric constants within a function shall be interpreted in the base specified by the value of the **ibase** register when the function is invoked.

The **return** statements (**return** and **return**(*expression*)) shall cause termination of a function, popping of its auto variables, and specification of the result of the function. The first form shall be equivalent to **return**(0). The value and scale of the result returned by the function shall be the value and scale of the expression returned.

The **quit** statement (**quit**) shall stop execution of a *bc* program at the point where the statement occurs in the input, even if it occurs in a function definition, or in an **if**, **for**, or **while** statement.

The following functions shall be defined when the **–l** option is specified:

s(*expression*)
: Sine of argument in radians.

c(*expression*)
: Cosine of argument in radians.

a(*expression*)
: Arctangent of argument.

l(*expression*)
: Natural logarithm of argument.

e(*expression*)
: Exponential function of argument.

j(*expression1*, *expression2*)
: Bessel function of *expression2* of the first kind of integer order *expression1*.

The scale of the result returned by these functions shall be the value of the **scale** register at the time the function is invoked. The value of the **scale** register after these functions have completed their execution shall be the same value it had upon invocation. The behavior is undefined if any of these functions is invoked with an argument outside the domain of the mathematical function.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

unspecified An error occurred.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *bc* shall write a diagnostic message to standard error and terminate without any further action.

In an interactive invocation of *bc*, the utility should print an error message and recover following any error in the input. In a non-interactive invocation of *bc*, invalid input causes undefined behavior.

APPLICATION USAGE

Automatic variables in *bc* do not work in exactly the same way as in either C or PL/1.

For historical reasons, the exit status from *bc* cannot be relied upon to indicate that an error has occurred. Returning zero after an error is possible. Therefore, *bc* should be used primarily by interactive users (who can react to error messages) or by application programs that can somehow validate the answers returned as not including error messages.

The *bc* utility always uses the <period> (`'.'`) character to represent a radix point, regardless of any decimal-point character specified as part of the current locale. In languages like C or *awk*, the <period> character is used in program source, so it can be portable and unambiguous, while the locale-specific character is used in input and output. Because there is no distinction between source and input in *bc*, this arrangement would not be possible. Using the locale-specific character in *bc*'s input would introduce ambiguities into the language; consider the following example in a locale with a <comma> as the decimal-point character:

```
define f(a,b) {
    ...
}
...
f(1,2,3)
```

Because of such ambiguities, the <period> character is used in input. Having input follow different conventions from output would be confusing in either pipeline usage or interactive usage, so the <period> is also used in output.

EXAMPLES

In the shell, the following assigns an approximation of the first ten digits of `'π'` to the variable *x*:

```
x=$(printf "%s\n" 'scale = 10; 104348/33215' | bc)
```

The following *bc* program prints the same approximation of `'π'`, with a label, to standard output:

```
scale = 10
"pi equals "
104348 / 33215
```

The following defines a function to compute an approximate value of the exponential function (note that such a function is predefined if the **–l** option is specified):

```
scale = 20
define e(x){
    auto a, b, c, i, s
```

```
        a = 1
        b = 1
        s = 1
        for (i = 1; 1 == 1; i++){
            a = a*x
            b = b*i
            c = a/b
            if (c == 0) {
                 return(s)
            }
            s = s+c
        }
    }
```

The following prints approximate values of the exponential function of the first ten integers:

```
    for (i = 1; i <= 10; ++i) {
        e(i)
    }
```

RATIONALE

The *bc* utility is implemented historically as a front-end processor for *dc*; *dc* was not selected to be part of this volume of POSIX.1-2017 because *bc* was thought to have a more intuitive programmatic interface. Current implementations that implement *bc* using *dc* are expected to be compliant.

The exit status for error conditions has been left unspecified for several reasons:

> The *bc* utility is used in both interactive and non-interactive situations. Different exit codes may be appropriate for the two uses.
>
> It is unclear when a non-zero exit should be given; divide-by-zero, undefined functions, and syntax errors are all possibilities.
>
> It is not clear what utility the exit status has.
>
> In the 4.3 BSD, System V, and Ninth Edition implementations, *bc* works in conjunction with *dc*. The *dc* utility is the parent, *bc* is the child. This was done to cleanly terminate *bc* if *dc* aborted.

The decision to have *bc* exit upon encountering an inaccessible input file is based on the belief that *bc file1 file2* is used most often when at least *file1* contains data/function declarations/initializations. Having *bc* continue with prerequisite files missing is probably not useful. There is no implication in the CONSEQUENCES OF ERRORS section that *bc* must check all its files for accessibility before opening any of them.

There was considerable debate on the appropriateness of the language accepted by *bc*. Several reviewers preferred to see either a pure subset of the C language or some changes to make the language more compatible with C. While the *bc* language has some obvious similarities to C, it has never claimed to be compatible with any version of C. An interpreter for a subset of C might be a very worthwhile utility, and it could potentially make *bc* obsolete. However, no such utility is known in historical practice, and it was not within the scope of this volume of POSIX.1-2017 to define such a language and utility. If and when they are defined, it may be appropriate to include them in a future version of this standard. This left the following alternatives:

1. Exclude any calculator language from this volume of POSIX.1-2017.

   The consensus of the standard developers was that a simple programmatic calculator language is very useful for both applications and interactive users. The only arguments for excluding any calculator were that it would become obsolete if and when a C-compatible one emerged, or that the absence would encourage the development of such a C-compatible one. These arguments did not sufficiently address the needs of current application developers.

2. Standardize the historical *dc*, possibly with minor modifications.

   The consensus of the standard developers was that *dc* is a fundamentally less usable language and that that would be far too severe a penalty for avoiding the issue of being similar to but incompatible with C.

3. Standardize the historical *bc*, possibly with minor modifications.

   This was the approach taken. Most of the proponents of changing the language would not have been satisfied until most or all of the incompatibilities with C were resolved. Since most of the changes considered most desirable would break historical applications and require significant modification to historical implementations, almost no modifications were made. The one significant modification that was made was the replacement of the historical *bc* assignment operators "=+", and so on, with the more modern "+=", and so on. The older versions are considered to be fundamentally flawed because of the lexical ambiguity in uses like *a*=–1.

   In order to permit implementations to deal with backwards-compatibility as they see fit, the behavior of this one ambiguous construct was made undefined. (At least three implementations have been known to support this change already, so the degree of change involved should not be great.)

The '%' operator is the mathematical remainder operator when **scale** is zero. The behavior of this operator for other values of **scale** is from historical implementations of *bc*, and has been maintained for the sake of historical applications despite its non-intuitive nature.

Historical implementations permit setting **ibase** and **obase** to a broader range of values. This includes values less than 2, which were not seen as sufficiently useful to standardize. These implementations do not interpret input properly for values of **ibase** that are greater than 16. This is because numeric constants are recognized syntactically, rather than lexically, as described in this volume of POSIX.1-2017. They are built from lexical tokens of single hexadecimal digits and <period> characters. Since <blank> characters between tokens are not visible at the syntactic level, it is not possible to recognize the multi-digit ``digits'' used in the higher bases properly. The ability to recognize input in these bases was not considered useful enough to require modifying these implementations. Note that the recognition of numeric constants at the syntactic level is not a problem with conformance to this volume of POSIX.1-2017, as it does not impact the behavior of conforming applications (and correct *bc* programs). Historical implementations also accept input with all of the digits '0'–'9' and 'A'–'F' regardless of the value of **ibase**; since digits with value greater than or equal to **ibase** are not really appropriate, the behavior when they appear is undefined, except for the common case of:

```
ibase=8;
    /* Process in octal base. */
...
ibase=A
    /* Restore decimal base. */
```

In some historical implementations, if the expression to be written is an uninitialized array

element, a leading <space> and/or up to four leading 0 characters may be output before the character zero. This behavior is considered a bug; it is unlikely that any currently conforming application relies on:

```
echo 'b[3]' | bc
```

returning 00000 rather than 0.

Exact calculation of the number of fractional digits to output for a given value in a base other than 10 can be computationally expensive. Historical implementations use a faster approximation, and this is permitted. Note that the requirements apply only to values of **obase** that this volume of POSIX.1-2017 requires implementations to support (in particular, not to 1, 0, or negative bases, if an implementation supports them as an extension).

Historical implementations of *bc* did not allow array parameters to be passed as the last parameter to a function. New implementations are encouraged to remove this restriction even though it is not required by the grammar.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 1.3 (on page 2335), *awk*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

Updated to align with the IEEE P1003.2b draft standard, which included resolution of several interpretations of the ISO POSIX-2: 1993 standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0066 [584] and XCU/TC2-2008/0067 [679] are applied.

NAME

bg — run jobs in the background

SYNOPSIS

UP

```
bg [job_id...]
```

DESCRIPTION

If job control is enabled (see the description of *set* **–m**), the *bg* utility shall resume suspended jobs from the current environment (see Section 2.12, on page 2381) by running them as background jobs. If the job specified by *job_id* is already a running background job, the *bg* utility shall have no effect and shall exit successfully.

Using *bg* to place a job into the background shall cause its process ID to become ``known in the current shell execution environment'', as if it had been started as an asynchronous list; see Section 2.9.3.1 (on page 2370).

OPTIONS

None.

OPERANDS

The following operand shall be supported:

job_id Specify the job to be resumed as a background job. If no *job_id* operand is given, the most recently suspended job shall be used. The format of *job_id* is described in XBD Section 3.204 (on page 66).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *bg*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output of *bg* shall consist of a line in the format:

```
"[%d] %s\n", <job-number>, <command>
```

where the fields are as follows:

<*job-number*> A number that can be used to identify the job to the *wait*, *fg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.

<*command*> The associated command that was given to the shell.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If job control is disabled, the *bg* utility shall exit with an error and no job shall be placed in the background.

APPLICATION USAGE

A job is generally suspended by typing the SUSP character (<control>-Z on most systems); see XBD Chapter 11 (on page 199). At that point, *bg* can put the job into the background. This is most effective when the job is expecting no terminal input and its output has been redirected to non-terminal files. A background job can be forced to stop when it has terminal output by issuing the command:

```
stty tostop
```

A background job can be stopped with the command:

```
kill –s stop job ID
```

The *bg* utility does not work as expected when it is operating in its own utility execution environment because that environment has no suspended jobs. In the following examples:

```
... | xargs bg
(bg)
```

each *bg* operates in a different environment and does not share its parent shell's understanding of jobs. For this reason, *bg* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The extensions to the shell specified in this volume of POSIX.1-2017 have mostly been based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of POSIX.1-2017 to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

The *bg* utility is expected to wrap its output if the output exceeds the number of display columns.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The JC margin marker on the SYNOPSIS is removed since support for Job Control is mandatory in this version. This is a FIPS requirement.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

c99 ‡ compile standard C programs

SYNOPSIS

CD

```
c99 [options...] pathname [[pathname] [-I directory]
    [-L directory] [-l library]]...
```

DESCRIPTION

The *c99* utility is an interface to the standard C compilation system; it shall accept source code conforming to the ISO C standard. The system conceptually consists of a compiler and link editor. The input files referenced by *pathname* operands and **-l** option-arguments shall be compiled and linked to produce an executable file. (It is unspecified whether the linking occurs entirely within the operation of *c99*; some implementations may produce objects that are not fully resolved until the file is executed.)

If the **-c** option is specified, for all pathname operands of the form *file***.c**, the files:

```
$(basename pathname .c).o
```

shall be created as the result of successful compilation. If the **-c** option is not specified, it is unspecified whether such **.o** files are created or deleted for the *file***.c** operands.

If there are no options that prevent link editing (such as **-c** or **-E**), and all input files compile and link without error, the resulting executable file shall be written according to the **-o** *outfile* option (if present) or to the file **a.out**.

The executable file shall be created as specified in Section 1.1.1.4 (on page 2328), except that the file permission bits shall be set to:

S_IRWXO | S_IRWXG | S_IRWXU

and the bits specified by the *umask* of the process shall be cleared.

OPTIONS

The *c99* utility shall conform to XBD Section 12.2 (on page 216), except that:

Options can be interspersed with operands.

The order of specifying the **-L** and **-l** options, and the order of specifying **-l** options with respect to *pathname* operands is significant.

Conforming applications shall specify each option separately; that is, grouping option letters (for example, **-cO**) need not be recognized by all implementations.

The following options shall be supported:

-c Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.

-D *name*[**=***value*]
Define *name* as if by a C-language **#define** directive. If no =*value* is given, a value of 1 shall be used. The **-D** option has lower precedence than the **-U** option. That is, if *name* is used in both a **-U** and a **-D** option, *name* shall be undefined regardless of the order of the options. Additional implementation-defined *name*s may be provided by the compiler. Implementations shall support at least 2 048 bytes of **-D** definitions and 256 *names*.

82260 **−E** Copy C-language source files to standard output, executing all preprocessor
82261 directives; no compilation shall be performed. If any operand is not a text file, the
82262 effects are unspecified.

82263 **−g** Produce symbolic information in the object or executable files; the nature of this
82264 information is unspecified, and may be modified by implementation-defined
82265 interactions with other options.

82266 **−I** *directory* Change the algorithm for searching for headers whose names are not absolute
82267 pathnames to look in the directory named by the *directory* pathname before looking
82268 in the usual places. Thus, headers whose names are enclosed in double-quotes (`" "`)
82269 shall be searched for first in the directory of the file with the **#include** line, then in
82270 directories named in **−I** options, and last in the usual places. For headers whose
82271 names are enclosed in angle brackets (`"<>"`), the header shall be searched for only
82272 in directories named in **−I** options and then in the usual places. Directories named
82273 in **−I** options shall be searched in the order specified. If the **−I** option is used to
82274 specify a directory that is one of the usual places searched by default, the results
82275 are unspecified. Implementations shall support at least ten instances of this option
82276 in a single *c99* command invocation.

82277 **−L** *directory* Change the algorithm of searching for the libraries named in the **−l** objects to look
82278 in the directory named by the *directory* pathname before looking in the usual
82279 places. Directories named in **−L** options shall be searched in the order specified. If
82280 the **−L** option is used to specify a directory that is one of the usual places searched
82281 by default, the results are unspecified. Implementations shall support at least ten
82282 instances of this option in a single *c99* command invocation. If a directory specified
82283 by a **−L** option contains files with names starting with any of the strings `"libc."`,
82284 `"libl."`, `"libpthread."`, `"libm."`, `"librt."`, `"libtrace."`, `"libxnet."`,
82285 or `"liby."`, the results are unspecified.

82286 **−l** *library* Search the library named **liblibrary.a**. A library shall be searched when its name is
82287 encountered, so the placement of a **−l** option is significant. Several standard
82288 libraries can be specified in this manner, as described in the EXTENDED
82289 DESCRIPTION section. Implementations may recognize implementation-defined
82290 suffixes other than **.a** as denoting libraries.

82291 **−O** *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit
82292 `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the
82293 nature of the optimization is unspecified. If the **−O** option is omitted, the nature of
82294 the system's default optimization is unspecified. It is unspecified whether code
82295 generated in the presence of the **−O** 0 option is the same as that generated when
82296 **−O** is omitted. Other *optlevel* values may be supported.

82297 **−o** *outfile* Use the pathname *outfile*, instead of the default **a.out**, for the executable file
82298 produced. If the **−o** option is present with **−c** or **−E**, the result is unspecified.

82299 **−s** Produce object or executable files, or both, from which symbolic and other
82300 information not required for proper execution using the *exec* family defined in the
82301 System Interfaces volume of POSIX.1-2017 has been removed (stripped). If both **−g**
82302 and **−s** options are present, the action taken is unspecified.

82303 **−U** *name* Remove any initial definition of *name*.

82304 Multiple instances of the **−D**, **−I**, **−L**, **−l**, and **−U** options can be specified.

82305 **OPERANDS**

82306 The application shall ensure that at least one *pathname* operand is specified. The following forms
82307 for *pathname* operands shall be supported:

82308 *file*.**c** A C-language source file to be compiled and optionally linked. The application
82309 shall ensure that the operand is of this form if the **−c** option is used.

82310 *file*.**a** A library of object files typically produced by the *ar* utility, and passed directly to
82311 the link editor. Implementations may recognize implementation-defined suffixes
82312 other than **.a** as denoting object file libraries.

82313 *file*.**o** An object file produced by *c99* **−c** and passed directly to the link editor.
82314 Implementations may recognize implementation-defined suffixes other than **.o** as
82315 denoting object files.

82316 The processing of other files is implementation-defined.

82317 **STDIN**

82318 Not used.

82319 **INPUT FILES**

82320 Each input file shall be one of the following: a text file containing a C-language source program,
82321 an object file in the format produced by *c99* **−c**, or a library of object files, in the format produced
82322 by archiving zero or more object files, using *ar*. Implementations may supply additional utilities
82323 that produce files in these formats. Additional input file formats are implementation-defined.

82324 **ENVIRONMENT VARIABLES**

82325 The following environment variables shall affect the execution of *c99*:

82326 *LANG* Provide a default value for the internationalization variables that are unset or null.
82327 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
82328 variables used to determine the values of locale categories.)

82329 *LC_ALL* If set to a non-empty string value, override the values of all the other
82330 internationalization variables.

82331 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
82332 characters (for example, single-byte as opposed to multi-byte characters in
82333 arguments and input files).

82334 *LC_MESSAGES*

82335 Determine the locale that should be used to affect the format and contents of
82336 diagnostic messages written to standard error.

82337 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

82338 *TMPDIR* Provide a pathname that should override the default directory for temporary files,
82339 XSI if any. On XSI-conforming systems, provide a pathname that shall override the
82340 default directory for temporary files, if any.

82341 **ASYNCHRONOUS EVENTS**

82342 Default.

82343 **STDOUT**

82344 If more than one *pathname* operand ending in **.c** (or possibly other unspecified suffixes) is given,
82345 for each such file:

82346 `"%s:\n", <pathname>`

82347 may be written. These messages, if written, shall precede the processing of each input file; they

shall not be written to the standard output if they are written to the standard error, as described in the STDERR section.

If the **−E** option is specified, the standard output shall be a text file that represents the results of the preprocessing stage of the language; it may contain extra information appropriate for subsequent compilation passes.

STDERR

The standard error shall be used only for diagnostic messages. If more than one *pathname* operand ending in **.c** (or possibly other unspecified suffixes) is given, for each such file:

`"%s:\n", <pathname>`

may be written to allow identification of the diagnostic and warning messages with the appropriate input file. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard error if they are written to the standard output, as described in the STDOUT section.

This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

OUTPUT FILES

Object files or executable files or both are produced in unspecified formats. If the pathname of an object file or executable file to be created by *c99* resolves to an existing directory entry for a file that is not a regular file, it is unspecified whether *c99* shall attempt to create the file or shall issue a diagnostic and exit with a non-zero exit status.

EXTENDED DESCRIPTION

Standard Libraries

The *c99* utility shall recognize the following **−l** options for standard libraries:

−l c This option shall make available all interfaces referenced in the System Interfaces volume of POSIX.1-2017, with the possible exception of those interfaces listed as residing in **<aio.h>**, **<arpa/inet.h>**, **<complex.h>**, **<fenv.h>**, **<math.h>**, **<mqueue.h>**, **<netdb.h>**, **<net/if.h>**, **<netinet/in.h>**, **<pthread.h>**, **<sched.h>**, **<semaphore.h>**, **<spawn.h>**, **<sys/socket.h>**, *pthread_kill*( ), and *pthread_sigmask*( ) in **<signal.h>**, **<trace.h>**, interfaces marked as optional in **<sys/mman.h>**, interfaces marked as ADV (Advisory Information) in **<fcntl.h>**, and interfaces beginning with the prefix clock_ or timer_ in **<time.h>**. This option shall not be required to be present to cause a search of this library.

−l l This option shall make available all interfaces required by the C-language output of *lex* that are not made available through the **−l c** option.

−l pthread This option shall make available all interfaces referenced in **<pthread.h>** and *pthread_kill*( ) and *pthread_sigmask*( ) referenced in **<signal.h>**. An implementation may search this library in the absence of this option.

−l m This option shall make available all interfaces referenced in **<math.h>**, **<complex.h>**, and **<fenv.h>**. An implementation may search this library in the absence of this option.

−l rt This option shall make available all interfaces referenced in **<aio.h>**, **<mqueue.h>**, **<sched.h>**, **<semaphore.h>**, and **<spawn.h>**, interfaces marked as optional in **<sys/mman.h>**, interfaces marked as ADV (Advisory Information) in **<fcntl.h>**, and interfaces beginning with the prefix clock_ and timer_ in **<time.h>**. An

82392 implementation may search this library in the absence of this option.

82393 OB **–l trace** This option shall make available all interfaces referenced in **<trace.h>**. An
82394 implementation may search this library in the absence of this option.

82395 **–l xnet** This option shall make available all interfaces referenced in **<arpa/inet.h>**,
82396 **<netdb.h>**, **<net/if.h>**, **<netinet/in.h>**, and **<sys/socket.h>**. An implementation
82397 may search this library in the absence of this option.

82398 **–l y** This option shall make available all interfaces required by the C-language output
82399 of *yacc* that are not made available through the **–l c** option.

82400 In the absence of options that inhibit invocation of the link editor, such as **–c** or **–E**, the *c99* utility
82401 shall cause the equivalent of a **–l c** option to be passed to the link editor after the last *pathname*
82402 operand or **–l** option, causing it to be searched after all other object files and libraries are loaded.

82403 OB It is unspecified whether the libraries **libc.a**, **libl.a**, **libm.a**, **libpthread.a**, **librt.a**, **libtrace.a**,
82404 **libxnet.a**, or **liby.a** exist as regular files. The implementation may accept as **–l** option-arguments
82405 names of objects that do not exist as regular files.

82406 **External Symbols**

82407 The C compiler and link editor shall support the significance of external symbols up to a length
82408 of at least 31 bytes; the action taken upon encountering symbols exceeding the implementation-
82409 defined maximum symbol length is unspecified.

82410 The compiler and link editor shall support a minimum of 511 external symbols per source or
82411 object file, and a minimum of 4 095 external symbols in total. A diagnostic message shall be
82412 written to the standard output if the implementation-defined limit is exceeded; other actions are
82413 unspecified.

82414 **Header Search**

82415 If a file with the same name as one of the standard headers defined in XBD Chapter 13 (on page
82416 219), not provided as part of the implementation, is placed in any of the usual places that are
82417 searched by default for headers, the results are unspecified.

82418 **Programming Environments**

82419 All implementations shall support one of the following programming environments as a default.
82420 Implementations may support more than one of the following programming environments.
82421 Applications can use *sysconf*( ) or *getconf* to determine which programming environments are
82422 supported.

82423 **Table 4-4** Programming Environments: Type Sizes

82424 82425 **Programming Environment *getconf* Name**	**Bits in int**	**Bits in long**	**Bits in pointer**	**Bits in off_t**
82426 _POSIX_V7_ILP32_OFF32	32	32	32	32
82427 _POSIX_V7_ILP32_OFFBIG	32	32	32	≥64
82428 _POSIX_V7_LP64_OFF64	32	64	64	64
82429 _POSIX_V7_LPBIG_OFFBIG	≥32	≥64	≥64	≥64

82430 All implementations shall support one or more environments where the widths of the following
82431 types are no greater than the width of type **long**:

82432 **blksize_t** **ptrdiff_t** **tcflag_t**
82433 **cc_t** **size_t** **wchar_t**
82434 **mode_t** **speed_t** **wint_t**
82435 **nfds_t** **ssize_t**
82436 **pid_t** **suseconds_t**

82437 The executable files created when these environments are selected shall be in a proper format for
82438 execution by the *exec* family of functions. Each environment may be one of the ones in Table 4-4,
82439 or it may be another environment. The names for the environments that meet this requirement
82440 shall be output by a *getconf* command using the POSIX_V7_WIDTH_RESTRICTED_ENVS
82441 argument, as a <newline>-separated list of names suitable for use with the *getconf* **–v** option. If
82442 more than one environment meets the requirement, the names of all such environments shall be
82443 output on separate lines. Any of these names can then be used in a subsequent *getconf* command
82444 to obtain the flags specific to that environment with the following suffixes added as appropriate:

82445 _CFLAGS To get the C compiler flags.

82446 _LDFLAGS To get the linker/loader flags.

82447 _LIBS To get the libraries.

82448 This requirement may be removed in a future version.

82449 When this utility processes a file containing a function called *main*(), it shall be defined with a
82450 return type equivalent to **int**. Using return from the initial call to *main*() shall be equivalent
82451 (other than with respect to language scope issues) to calling *exit*() with the returned value.
82452 Reaching the end of the initial call to *main*() shall be equivalent to calling *exit*(0). The
82453 implementation shall not declare a prototype for this function.

82454 Implementations provide configuration strings for C compiler flags, linker/loader flags, and
82455 libraries for each supported environment. When an application needs to use a specific
82456 programming environment rather than the implementation default programming environment
82457 while compiling, the application shall first verify that the implementation supports the desired
82458 environment. If the desired programming environment is supported, the application shall then
82459 invoke *c99* with the appropriate C compiler flags as the first options for the compile, the
82460 appropriate linker/loader flags after any other options except **–l** but before any operands or **–l**
82461 options, and the appropriate libraries at the end of the operands and **–l** options.

82462 Conforming applications shall not attempt to link together object files compiled for different
82463 programming models. Applications shall also be aware that binary data placed in shared
82464 memory or in files might not be recognized by applications built for other programming models.

Table 4-5 Programming Environments: *c99* Arguments

Programming Environment *getconf* **Name**	**Use**	*c99* **Arguments** *getconf* **Name**
_POSIX_V7_ILP32_OFF32	C Compiler Flags	POSIX_V7_ILP32_OFF32_CFLAGS
	Linker/Loader Flags	POSIX_V7_ILP32_OFF32_LDFLAGS
	Libraries	POSIX_V7_ILP32_OFF32_LIBS
_POSIX_V7_ILP32_OFFBIG	C Compiler Flags	POSIX_V7_ILP32_OFFBIG_CFLAGS
	Linker/Loader Flags	POSIX_V7_ILP32_OFFBIG_LDFLAGS
	Libraries	POSIX_V7_ILP32_OFFBIG_LIBS
_POSIX_V7_LP64_OFF64	C Compiler Flags	POSIX_V7_LP64_OFF64_CFLAGS
	Linker/Loader Flags	POSIX_V7_LP64_OFF64_LDFLAGS
	Libraries	POSIX_V7_LP64_OFF64_LIBS
_POSIX_V7_LPBIG_OFFBIG	C Compiler Flags	POSIX_V7_LPBIG_OFFBIG_CFLAGS
	Linker/Loader Flags	POSIX_V7_LPBIG_OFFBIG_LDFLAGS
	Libraries	POSIX_V7_LPBIG_OFFBIG_LIBS

In addition to the type size programming environments above, all implementations also support a multi-threaded programming environment that is orthogonal to all of the programming environments listed above. The *getconf* utility can be used to get flags for the threaded programming environment, as indicated in Table 4-6.

Table 4-6 Threaded Programming Environment: *c99* Arguments

Programming Environment *getconf* **Name**	**Use**	*c99* **Arguments** *getconf* **Name**
_POSIX_THREADS	C Compiler Flags	POSIX_V7_THREADS_CFLAGS
	Linker/Loader Flags	POSIX_V7_THREADS_LDFLAGS

These programming environment flags may be used in conjunction with any of the type size programming environments supported by the implementation.

EXIT STATUS

The following exit values shall be returned:

0 Successful compilation or link edit.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When *c99* encounters a compilation error that causes an object file not to be created, it shall write a diagnostic to standard error and continue to compile other source code operands, but it shall not perform the link phase and it shall return a non-zero exit status. If the link edit is unsuccessful, a diagnostic message shall be written to standard error and *c99* exits with a non-zero status. A conforming application shall rely on the exit status of *c99*, rather than on the existence or mode of the executable file.

APPLICATION USAGE

Since the *c99* utility usually creates files in the current directory during the compilation process, it is typically necessary to run the *c99* utility in a directory in which a file can be created.

On systems providing POSIX Conformance (see XBD Chapter 2, on page 15), *c99* is required only with the C-Language Development option; XSI-conformant systems always provide *c99*.

Some historical implementations have created **.o** files when **−c** is not specified and more than one source file is given. Since this area is left unspecified, the application cannot rely on **.o** files being created, but it also must be prepared for any related **.o** files that already exist being deleted at the completion of the link edit.

There is the possible implication that if a user supplies versions of the standard functions (before they would be encountered by an implicit **−l c** or explicit **−l m**), that those versions would be used in place of the standard versions. There are various reasons this might not be true (functions defined as macros, manipulations for clean name space, and so on), so the existence of files named in the same manner as the standard libraries within the **−L** directories is explicitly stated to produce unspecified behavior.

All of the functions specified in the System Interfaces volume of POSIX.1-2017 may be made visible by implementations when the Standard C Library is searched. Conforming applications must explicitly request searching the other standard libraries when functions made visible by those libraries are used.

In the ISO C standard the mapping from physical source characters to the C source character set is implementation-defined. Implementations may strip white-space characters before the terminating <newline> of a (physical) line as part of this mapping and, as a consequence of this, one or more white-space characters (and no other characters) between a <backslash> character and the <newline> character that terminates the line produces implementation-defined results. Portable applications should not use such constructs.

Some *c99* compilers not conforming to POSIX.1-2017 do not support trigraphs by default.

EXAMPLES

1. The following usage example compiles **foo.c** and creates the executable file **foo**:

   ```
   c99 −o foo foo.c
   ```

   The following usage example compiles **foo.c** and creates the object file **foo.o**:

   ```
   c99 −c foo.c
   ```

   The following usage example compiles **foo.c** and creates the executable file **a.out**:

   ```
   c99 foo.c
   ```

   The following usage example compiles **foo.c**, links it with **bar.o**, and creates the executable file **a.out**. It may also create and leave **foo.o**:

   ```
   c99 foo.c bar.o
   ```

2. The following example shows how an application using threads interfaces can test for support of and use a programming environment supporting 32-bit **int**, **long**, and **pointer** types and an **off_t** type using at least 64 bits:

   ```
   offbig_env=$(getconf _POSIX_V7_ILP32_OFFBIG)
   if [ $offbig_env != "-1" ] && [ $offbig_env != "undefined" ]
   then
       c99 $(getconf POSIX_V7_ILP32_OFFBIG_CFLAGS) \
   ```

```
        $(getconf POSIX_V7_THREADS_CFLAGS) -D_XOPEN_SOURCE=700 \
        $(getconf POSIX_V7_ILP32_OFFBIG_LDFLAGS) \
        $(getconf POSIX_V7_THREADS_LDFLAGS) foo.c -o foo \
        $(getconf POSIX_V7_ILP32_OFFBIG_LIBS) \
        -l pthread
else
        echo ILP32_OFFBIG programming environment not supported
        exit 1
fi
```

3. The following examples clarify the use and interactions of **–L** and **–l** options.

   Consider the case in which module **a.c** calls function *f*( ) in library **libQ.a**, and module **b.c** calls function *g*( ) in library **libp.a**. Assume that both libraries reside in **/a/b/c**. The command line to compile and link in the desired way is:

   ```
   c99 –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this case the **–L** option need only precede the first **–l** option, since both **libQ.a** and **libp.a** reside in the same directory.

   Multiple **–L** options can be used when library name collisions occur. Building on the previous example, suppose that the user wants to use a new **libp.a**, in **/a/a/a**, but still wants *f*( ) from **/a/b/c/libQ.a**:

   ```
   c99 –L /a/a/a –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this example, the linker searches the **–L** options in the order specified, and finds **/a/a/a/libp.a** before **/a/b/c/libp.a** when resolving references for **b.c**. The order of the **–l** options is still important, however.

4. The following example shows how an application can use a programming environment where the widths of the following types:

   blksize_t, **cc_t**, **mode_t**, **nfds_t**, **pid_t**, **ptrdiff_t**, **size_t**, **speed_t**, **ssize_t**, **suseconds_t**, **tcflag_t**, **wchar_t**, **wint_t**

   are no greater than the width of type **long**:

   ```
   # First choose one of the listed environments ...
   # ... if there are no additional constraints, the first one will do:
   CENV=$(getconf POSIX_V7_WIDTH_RESTRICTED_ENVS | head -n 1)
   # ... or, if an environment that supports large files is preferred,
   # look for names that contain "OFF64" or "OFFBIG". (This chooses
   # the last one in the list if none match.)
   for CENV in $(getconf POSIX_V7_WIDTH_RESTRICTED_ENVS)
   do
       case $CENV in
       *OFF64*|*OFFBIG*) break ;;
       esac
   done
   # The chosen environment name can now be used like this:
   c99 $(getconf ${CENV}_CFLAGS) -D _POSIX_C_SOURCE=200809L \
   $(getconf ${CENV}_LDFLAGS) foo.c -o foo \
   $(getconf ${CENV}_LIBS)
   ```

RATIONALE

The *c99* utility is based on the *c89* utility originally introduced in the ISO POSIX-2: 1993 standard.

Some of the changes from *c89* include the ability to intersperse options and operands (which many *c89* implementations allowed despite it not being specified), the description of **–l** as an option instead of an operand, and the modification to the contents of the Standard Libraries section to account for new headers and options; for example, **<spawn.h>** added to the description of **–l rt**, and **–l trace** added for the Tracing option.

POSIX.1-2017 specifies that the *c99* utility must be able to use regular files for ***.o** files and for **a.out** files. Implementations are free to overwrite existing files of other types when attempting to create object files and executable files, but are not required to do so. If something other than a regular file is specified and using it fails for any reason, *c99* is required to issue a diagnostic message and exit with a non-zero exit status. But for some file types, the problem may not be noticed for a long time. For example, if a FIFO named **a.out** exists in the current directory, *c99* may attempt to open **a.out** and will hang in the *open*( ) call until another process opens the FIFO for reading. Then *c99* may write most of the **a.out** to the FIFO and fail when it tries to seek back close to the start of the file to insert a timestamp (FIFOs are not seekable files). The *c99* utility is also allowed to issue a diagnostic immediately if it encounters an **a.out** or ***.o** file that is not a regular file. For portable use, applications should ensure that any **a.out**, **–o** option-argument, or ***.o** files corresponding to any ***.c** files do not conflict with names already in use that are not regular files or symbolic links that point to regular files.

On many systems, multi-threaded applications run in a programming environment that is distinct from that used by single-threaded applications. This multi-threaded programming environment (in addition to needing to specify **–l pthread** at link time) may require additional flags to be set when headers are processed at compile time (**–D_REENTRANT** being common). This programming environment is orthogonal to the type size programming environments discussed above and listed in Table 4-4 (on page 2547). This version of the standard adds *getconf* utility calls to provide the C compiler flags and linker/loader flags needed to support multi-threaded applications. Note that on a system where single-threaded applications are a special case of a multi-threaded application, both of these *getconf* calls may return NULL strings; on other implementations both of these strings may be non-NULL strings.

The C standardization committee invented trigraphs (e.g., `"??!"` to represent `'|'`) to address character portability problems in development environments based on national variants of the 7-bit ISO/IEC 646: 1991 standard character set. However, these environments were already obsolete by the time the first ISO C standard was published, and in practice trigraphs have not been used for their intended purpose, and usually are intended to have their original meaning in K&R C. For example, in practice a C-language source string like `"What??!"` is usually intended to end in two <question-mark> characters and an <exclamation-mark>, not in `'|'`.

When the **–E** option is used, execution of some **#pragma** preprocessor directives may simply result in a copy of the directive being included in the output as part of the allowed extra information used by subsequent compilation passes (see STDOUT).

FUTURE DIRECTIONS

Unlike all of the other non-OB-shaded utilities in this standard, a utility by this name probably will not appear in the next version of this standard. This utility's name is tied to the current revision of the ISO C standard at the time this standard is approved. Since the ISO C standard and this standard are maintained by different organizations on different schedules, we cannot predict what the compiler will be named in the next version of the standard.

CHANGE HISTORY

First released in Issue 6. Included for alignment with the ISO/IEC 9899: 1999 standard.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/12 is applied, correcting the EXTENDED DESCRIPTION of **–l c** and **–l m**. Previously, the text did not take into account the presence of the *c99* math headers.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/13 is applied, changing the reference to the **libxnet** library to **libxnet.a**.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/5 is applied, updating the OPTIONS section, so that the names of files contained in the directory specified by the **–L** option are not assumed to end in the **.a** suffix. The set of library prefixes is also updated.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/6 is applied, removing the lead underscore from the POSIX_V6_WIDTH_RESTRICTED_ENVS variable in the EXTENDED DESCRIPTION and the EXAMPLES sections.

Issue 7

Austin Group Interpretation 1003.1-2001 #020 (SD5-XCU-ERN-10) is applied, adding to the OUTPUT FILES section and also adding associated RATIONALE.

Austin Group Interpretation 1003.1-2001 #095 is applied, clarifying the **–l** *library* operand.

Austin Group Interpretation 1003.1-2001 #166 is applied.

Austin Group Interpretation 1003.1-2001 #190 is applied, clarifying the handling of trailing white-space characters.

Austin Group Interpretation 1003.1-2001 #191 is applied, adding APPLICATION USAGE and RATIONALE regarding C-language trigraphs.

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply (options can be interspersed with operands).

SD5-XCU-ERN-11 is applied, adding the **<net/if.h>** header to the descriptions of **–l c** and **–l xnet**.

SD5-XCU-ERN-65 is applied, updating the EXAMPLES section.

SD5-XCU-ERN-67 and SD5-XCU-ERN-97 are applied, updating the SYNOPSIS.

SD5-XCU-ERN-133 is applied, updating the EXTENDED DESCRIPTION.

The *getconf* variables for the supported programming environments are updated to be V7.

The **–l trace** operand is marked obsolescent.

The *c99* reference page is rewritten to describe **–l** as an option rather than an operand.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0068 [129], XCU/TC1-2008/0069 [187], XCU/TC1-2008/0070 [187], XCU/TC1-2008/0071 [131], XCU/TC1-2008/0072 [187], and XCU/TC1-2008/0073 [364,430] are applied.

82675 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0068 [650], XCU/TC2-2008/0069
82676 [670], XCU/TC2-2008/0070 [638], XCU/TC2-2008/0071 [650], and XCU/TC2-2008/0072 [784]
82677 are applied.

NAME

cal ‡'print a calendar

SYNOPSIS

XSI
```
cal [[month] year]
```

DESCRIPTION

The *cal* utility shall write a calendar to standard output using the Julian calendar for dates from January 1, 1 through September 2, 1752 and the Gregorian calendar for dates from September 14, 1752 through December 31, 9999 as though the Gregorian calendar had been adopted on September 14, 1752.

If no operands are given, *cal* shall produce a one-month calendar for the current month in the current year. If only the *year* operand is given, *cal* shall produce a calendar for all twelve months in the given calendar year. If both *month* and *year* operands are given, *cal* shall produce a one-month calendar for the given month in the given year.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

month Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December).

year Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cal*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

LC_TIME Determine the format and contents of the calendar.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone used to calculate the value of the current month.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used to display the calendar, in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that:

```
cal 83
```

refers to A.D. 83, not 1983.

EXAMPLES

None.

RATIONALE

Earlier versions of this standard incorrectly required that the command:

```
cal 2000
```

write a one-month calendar for the current calendar month (no matter what the current year is) in the year 2000 to standard output. This did not match historic practice in any known version of the *cal* utility. The description has been updated to match historic practice. When only the *year* operand is given, *cal* writes a twelve-month calendar for the specified year.

FUTURE DIRECTIONS

A future version of this standard may support locale-specific recognition of the date of adoption of the Gregorian calendar.

Issue 6

The DESCRIPTION is updated to allow for traditional behavior for years before the adoption of the Gregorian calendar.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0074 [56] and XCU/TC1-2008/0075 [56] are applied.

NAME

cat ‡'concatenate and print files

SYNOPSIS

```
cat [−u] [file...]
```

DESCRIPTION

The *cat* utility shall read files in sequence and shall write their contents to the standard output in the same sequence.

OPTIONS

The *cat* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−u Write bytes from the input file to the standard output without delay as each is read.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, the standard input shall be used. If a *file* is `'−'`, the *cat* utility shall read from the standard input at that point in the sequence. The *cat* utility shall not close and reopen standard input when it is referenced in this way, but shall accept multiple occurrences of `'−'` as a *file* operand.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cat*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

82803 **STDOUT**

82804 The standard output shall contain the sequence of bytes read from the input files. Nothing else
82805 shall be written to the standard output. If the standard output is a regular file, and is the same
82806 file as any of the input file operands, the implementation may treat this as an error.

82807 **STDERR**

82808 The standard error shall be used only for diagnostic messages.

82809 **OUTPUT FILES**

82810 None.

82811 **EXTENDED DESCRIPTION**

82812 None.

82813 **EXIT STATUS**

82814 The following exit values shall be returned:

82815 0 All input files were output successfully.

82816 >0 An error occurred.

82817 **CONSEQUENCES OF ERRORS**

82818 Default.

82819 **APPLICATION USAGE**

82820 The **−u** option has value in prototyping non-blocking reads from FIFOs. The intent is to support
82821 the following sequence:

```
82822 mkfifo foo
82823 cat −u foo > /dev/tty13 &
82824 cat −u > foo
```

82825 It is unspecified whether standard output is or is not buffered in the default case. This is
82826 sometimes of interest when standard output is associated with a terminal, since buffering may
82827 delay the output. The presence of the **−u** option guarantees that unbuffered I/O is available. It is
82828 implementation-defined whether the *cat* utility buffers output if the **−u** option is not specified.
82829 Traditionally, the **−u** option is implemented using the equivalent of the *setvbuf*( ) function
82830 defined in the System Interfaces volume of POSIX.1-2017.

82831 **EXAMPLES**

82832 The following command:

```
82833 cat myfile
```

82834 writes the contents of the file **myfile** to standard output.

82835 The following command:

```
82836 cat doc1 doc2 > doc.all
```

82837 concatenates the files **doc1** and **doc2** and writes the result to **doc.all**.

82838 Because of the shell language mechanism used to perform output redirection, a command such
82839 as this:

```
82840 cat doc doc.end > doc
```

82841 causes the original data in **doc** to be lost before *cat* even begins execution. This is true whether
82842 the *cat* command fails with an error or silently succeeds (the specification allows both
82843 behaviors). In order to append the contents of **doc.end** without losing the original contents of
82844 **doc**, this command should be used instead:

```
cat doc.end >> doc
```

The command:

```
cat start - middle - end > file
```

when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a single invocation of *cat*. Note, however, that if standard input is a regular file, this would be equivalent to the command:

```
cat start - middle /dev/null end > file
```

because the entire contents of the file would be consumed by *cat* the first time '−' was used as a *file* operand and an end-of-file condition would be detected immediately when '−' was referenced the second time.

RATIONALE

Historical versions of the *cat* utility include the **−e**, **−t**, and **−v**, options which permit the ends of lines, <tab> characters, and invisible characters, respectively, to be rendered visible in the output. The standard developers omitted these options because they provide too fine a degree of control over what is made visible, and similar output can be obtained using a command such as:

```
sed −n l pathname
```

The latter also has the advantage that its output is unambiguous, whereas the output of historical *cat* **−etv** is not.

The **−s** option was omitted because it corresponds to different functions in BSD and System V-based systems. The BSD **−s** option to squeeze blank lines can be accomplished by the shell script shown in the following example:

```
sed −n '
# Write non-empty lines.
/./   {
      p
      d
      }
# Write a single empty line, then look for more empty lines.
/^$/  p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/  {
      N
      s/.//
      b Empty
      }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
      p
'
```

The System V **−s** option to silence error messages can be accomplished by redirecting the standard error. Note that the BSD documentation for *cat* uses the term ``blank line'' to mean the same as the POSIX ``empty line'': a line consisting only of a <newline>.

The BSD **−n** option was omitted because similar functionality can be obtained from the **−n** option of the *pr* utility.

FUTURE DIRECTIONS

None.

NAME

cd — change the working directory

SYNOPSIS

```
cd [-L|-P] [directory]
cd -
```

DESCRIPTION

The *cd* utility shall change the working directory of the current shell execution environment (see Section 2.12, on page 2381) by executing the following steps in sequence. (In the following steps, the symbol **curpath** represents an intermediate value used to simplify the description of the algorithm used by *cd*. There is no requirement that **curpath** be made visible to the application.)

1. If no *directory* operand is given and the *HOME* environment variable is empty or undefined, the default behavior is implementation-defined and no further steps shall be taken.
2. If no *directory* operand is given and the *HOME* environment variable is set to a non-empty value, the *cd* utility shall behave as if the directory named in the *HOME* environment variable was specified as the *directory* operand.
3. If the *directory* operand begins with a <slash> character, set **curpath** to the operand and proceed to step 7.
4. If the first component of the *directory* operand is dot or dot-dot, proceed to step 6.
5. Starting with the first pathname in the <colon>-separated pathnames of *CDPATH* (see the ENVIRONMENT VARIABLES section) if the pathname is non-null, test if the concatenation of that pathname, a <slash> character if that pathname did not end with a <slash> character, and the *directory* operand names a directory. If the pathname is null, test if the concatenation of dot, a <slash> character, and the operand names a directory. In either case, if the resulting string names an existing directory, set **curpath** to that string and proceed to step 7. Otherwise, repeat this step with the next pathname in *CDPATH* until all pathnames have been tested.
6. Set **curpath** to the *directory* operand.
7. If the **–P** option is in effect, proceed to step 10. If **curpath** does not begin with a <slash> character, set **curpath** to the string formed by the concatenation of the value of *PWD*, a <slash> character if the value of *PWD* did not end with a <slash> character, and **curpath**.
8. The **curpath** value shall then be converted to canonical form as follows, considering each component from beginning to end, in sequence:
    a. Dot components and any <slash> characters that separate them from the next component shall be deleted.
    b. For each dot-dot component, if there is a preceding component and it is neither root nor dot-dot, then:
        i. If the preceding component does not refer (in the context of pathname resolution with symbolic links followed) to a directory, then the *cd* utility shall display an appropriate error message and no further steps shall be taken.
        ii. The preceding component, all <slash> characters separating the preceding component from dot-dot, dot-dot, and all <slash> characters separating dot-dot from the following component (if any) shall be deleted.

c. An implementation may further simplify **curpath** by removing any trailing <slash> characters that are not also leading <slash> characters, replacing multiple non-leading consecutive <slash> characters with a single <slash>, and replacing three or more leading <slash> characters with a single <slash>. If, as a result of this canonicalization, the **curpath** variable is null, no further steps shall be taken.

9. If **curpath** is longer than {PATH_MAX} bytes (including the terminating null) and the *directory* operand was not longer than {PATH_MAX} bytes (including the terminating null), then **curpath** shall be converted from an absolute pathname to an equivalent relative pathname if possible. This conversion shall always be considered possible if the value of *PWD*, with a trailing <slash> added if it does not already have one, is an initial substring of **curpath**. Whether or not it is considered possible under other circumstances is unspecified. Implementations may also apply this conversion if **curpath** is not longer than {PATH_MAX} bytes or the *directory* operand was longer than {PATH_MAX} bytes.

10. The *cd* utility shall then perform actions equivalent to the *chdir*( ) function called with **curpath** as the *path* argument. If these actions fail for any reason, the *cd* utility shall display an appropriate error message and the remainder of this step shall not be executed. If the **−P** option is not in effect, the *PWD* environment variable shall be set to the value that **curpath** had on entry to step 9 (i.e., before conversion to a relative pathname). If the **−P** option is in effect, the *PWD* environment variable shall be set to the string that would be output by *pwd* **−P**. If there is insufficient permission on the new directory, or on any parent of that directory, to determine the current working directory, the value of the *PWD* environment variable is unspecified.

If, during the execution of the above steps, the *PWD* environment variable is set, the *OLDPWD* environment variable shall also be set to the value of the old working directory (that is the current working directory immediately prior to the call to *cd*).

OPTIONS

The *cd* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

−L Handle the operand dot-dot logically; symbolic link components shall not be resolved before dot-dot components are processed (see steps 8. and 9. in the DESCRIPTION).

−P Handle the operand dot-dot physically; symbolic link components shall be resolved before dot-dot components are processed (see step 7. in the DESCRIPTION).

If both **−L** and **−P** options are specified, the last of these options shall be used and all others ignored. If neither **−L** nor **−P** is specified, the operand shall be handled dot-dot logically; see the DESCRIPTION.

OPERANDS

The following operands shall be supported:

directory An absolute or relative pathname of the directory that shall become the new working directory. The interpretation of a relative pathname by *cd* depends on the **−L** option and the *CDPATH* and *PWD* environment variables. If *directory* is an empty string, the results are unspecified.

− When a <hyphen-minus> is used as the operand, this shall be equivalent to the command:

```
cd "$OLDPWD" && pwd
```

which changes to the previous working directory and then writes its name.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cd*:

CDPATH A <colon>-separated list of pathnames that refer to directories. The *cd* utility shall use this list in its attempt to change the directory, as described in the DESCRIPTION. An empty string in place of a directory pathname represents the current directory. If *CDPATH* is not set, it shall be treated as if it were an empty string.

HOME The name of the directory, used when no *directory* operand is specified.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

OLDPWD A pathname of the previous working directory, used by *cd* −.

PWD This variable shall be set as specified in the DESCRIPTION. If an application sets or unsets the value of *PWD*, the behavior of *cd* is unspecified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If a non-empty directory name from *CDPATH* is used, or if *cd* − is used, an absolute pathname of the new working directory shall be written to the standard output as follows:

```
"%s\n", <new directory>
```

Otherwise, there shall be no output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The directory was successfully changed.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The working directory shall remain unchanged.

APPLICATION USAGE

Since *cd* affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(cd /tmp)
nohup cd
find . –exec cd {} \;
```

it does not affect the working directory of the caller's environment.

The user must have execute (search) permission in *directory* in order to change to it.

EXAMPLES

The following template can be used to perform processing in the directory specified by *location* and end up in the current working directory in use before the first *cd* command was issued:

```
cd location
if [ $? –ne 0 ]
then
    print error message
    exit 1
fi
... do whatever is desired as long as the OLDPWD environment variable
    is not modified
cd –
```

RATIONALE

The use of the *CDPATH* was introduced in the System V shell. Its use is analogous to the use of the *PATH* variable in the shell. The BSD C shell used a shell parameter *cdpath* for this purpose.

A common extension when *HOME* is undefined is to get the login directory from the user database for the invoking user. This does not occur on System V implementations.

Some historical shells, such as the KornShell, took special actions when the directory name contained a dot-dot component, selecting the logical parent of the directory, rather than the actual parent directory; that is, it moved up one level toward the '/' in the pathname, remembering what the user typed, rather than performing the equivalent of:

```
chdir("..");
```

In such a shell, the following commands would not necessarily produce equivalent output for all directories:

```
cd .. && ls      ls ..
```

This behavior is now the default. It is not consistent with the definition of dot-dot in most

historical practice; that is, while this behavior has been optionally available in the KornShell, other shells have historically not supported this functionality. The logical pathname is stored in the *PWD* environment variable when the *cd* utility completes and this value is used to construct the next directory name if *cd* is invoked with the **−L** option.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

XSH *chdir*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The *cd* – operand, *PWD*, and *OLDPWD* are added.

The **−L** and **−P** options are added to align with the IEEE P1003.2b draft standard. This also includes the introduction of a new description to include the effect of these options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/14 is applied, changing the SYNOPSIS to make it clear that the **−L** and **−P** options are mutually-exclusive.

Issue 7

Austin Group Interpretation 1003.1-2001 #037 is applied.

Austin Group Interpretation 1003.1-2001 #199 is applied, clarifying how the *cd* utility handles concatenation of two pathnames when the first pathname ends in a <slash> character.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Step 7 of the processing performed by *cd* is revised to refer to **curpath** instead of ``the operand''.

Changes to the *pwd* utility and *PWD* environment variable have been made to match the changes to the *getcwd*( ) function made for Austin Group Interpretation 1003.1-2001 #140.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0076 [230], XCU/TC1-2008/0077 [240], XCU/TC1-2008/0078 [240], and XCU/TC1-2008/0079 [123] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0074 [584] is applied.

NAME

cflow ‡'generate a C-language flowgraph (**DEVELOPMENT**)

SYNOPSIS

XSI
```
cflow [−r] [−d num] [−D name[=def]]... [−i incl] [−I dir]...
    [−U dir]... file...
```

DESCRIPTION

The *cflow* utility shall analyze a collection of object files or assembler, C-language, *lex*, or *yacc* source files, and attempt to build a graph, written to standard output, charting the external references.

OPTIONS

The *cflow* utility shall conform to XBD Section 12.2 (on page 216), except that the order of the **−D**, **−I**, and **−U** options (which are identical to their interpretation by *c99*) is significant.

The following options shall be supported:

−d *num* Indicate the depth at which the flowgraph is cut off. The application shall ensure that the argument *num* is a decimal integer. By default this is a very large number (typically greater than 32 000). Attempts to set the cut-off depth to a non-positive integer shall be ignored.

−i *incl* Increase the number of included symbols. The *incl* option-argument is one of the following characters:

x Include external and static data symbols. The default shall be to include only functions in the flowgraph.

_ (Underscore) Include names that begin with an <underscore>. The default shall be to exclude these functions (and data if **−i x** is used).

−r Reverse the caller:callee relationship, producing an inverted listing showing the callers of each function. The listing shall also be sorted in lexicographical order by callee.

OPERANDS

The following operand is supported:

file The pathname of a file for which a graph is to be generated. Filenames suffixed by **.l** shall shall be taken to be *lex* input, **.y** as *yacc* input, **.c** as *c99* input, and **.i** as the output of *c99* **−E**. Such files shall be processed as appropriate, determined by their suffix.

Files suffixed by **.s** (conventionally assembler source) may have more limited information extracted from them.

STDIN

Not used.

INPUT FILES

The input files shall be object files or assembler, C-language, *lex*, or *yacc* source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cflow*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the ordering of the output when the **−r** option is used.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The flowgraph written to standard output shall be formatted as follows:

`"%d %s:%s\n", <reference number>, <global>, <definition>`

Each line of output begins with a reference (that is, line) number, followed by indentation of at least one column position per level. This is followed by the name of the global, a <colon>, and its definition. Normally globals are only functions not defined as an external or beginning with an <underscore>; see the OPTIONS section for the **−i** inclusion option. For information extracted from C-language source, the definition consists of an abstract type declaration (for example, **char** *) and, delimited by angle brackets, the name of the source file and the line number where the definition was found. Definitions extracted from object files indicate the filename and location counter under which the symbol appeared (for example, *text*).

Once a definition of a name has been written, subsequent references to that name contain only the reference number of the line where the definition can be found. For undefined references, only `"< >"` shall be written.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE

Files produced by *lex* and *yacc* cause the reordering of line number declarations, and this can confuse *cflow*. To obtain proper results, the input of *yacc* or *lex* must be directed to *cflow*.

EXAMPLES

Given the following in **file.c**:

```
int i;
int f();
int g();
int h();
int
main()
{
    f();
    g();
    f();
}
int
f()
{
    i = h();
}
```

The command:

```
cflow -i x file.c
```

produces the output:

```
1 main: int(), <file.c 6>
2    f: int(), <file.c 13>
3        h: <>
4        i: int, <file.c 1>
5    g: <>
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

chgrp — change the file group ownership

SYNOPSIS

```
chgrp [-h] group file...
chgrp -R [-H|-L|-P] group file...
```

DESCRIPTION

The *chgrp* utility shall set the group ID of the file named by each *file* operand to the group ID specified by the *group* operand.

For each *file* operand, or, if the **-R** option is used, each file encountered while walking the directory trees specified by the *file* operands, the *chgrp* utility shall perform actions equivalent to the *chown*() function defined in the System Interfaces volume of POSIX.1-2017, called with the following arguments:

The *file* operand shall be used as the *path* argument.

The user ID of the file shall be used as the *owner* argument.

The specified group ID shall be used as the *group* argument.

Unless *chgrp* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chgrp* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

-h For each *file* operand that names a file of type symbolic link, *chgrp* shall attempt to set the group ID of the symbolic link instead of the file referenced by the symbolic link.

-H If the **-R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

-L If the **-R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

-P If the **-R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group ID of the symbolic link. The *chgrp* utility shall not follow the symbolic link to any other part of the file hierarchy.

-R Recursively change file group IDs. For each *file* operand that names a directory, *chgrp* shall change the group of the directory and all files in the file hierarchy below it. Unless a **-H**, **-L**, or **-P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **-H**, **-L**, and **-P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

group A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the *file* operands. If a numeric *group* operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.

file A pathname of a file whose group ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chgrp*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of *chgrp* to a user with appropriate privileges when the *group* specified is not the effective group ID or one of the supplementary group IDs of the calling process.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. The standard developers chose to mask these by specifying only 0 and >0 as exit values.

The functionality of *chgrp* is described substantially through references to *chown*( ). In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

FUTURE DIRECTIONS

None.

NAME

chmod ‡'change the file modes

SYNOPSIS

```
chmod [-R] mode file...
```

DESCRIPTION

The *chmod* utility shall change any or all of the file mode bits of the file named by each *file* operand in the way specified by the *mode* operand.

It is implementation-defined whether and how the *chmod* utility affects any alternate or additional file access control mechanism (see XBD Section 4.5, on page 108) being used for the specified file.

Only a process whose effective user ID matches the user ID of the file, or a process with appropriate privileges, shall be permitted to change the file mode bits of a file.

Upon successfully changing the file mode bits of a file, the *chmod* utility shall mark for update the last file status change timestamp of the file.

OPTIONS

The *chmod* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-R Recursively change file mode bits. For each *file* operand that names a directory, *chmod* shall change the file mode bits of the directory and all files in the file hierarchy below it.

OPERANDS

The following operands shall be supported:

mode Represents the change to be made to the file mode bits of each file named by one of the *file* operands; see the EXTENDED DESCRIPTION section.

file A pathname of a file whose file mode bits shall be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chmod*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *mode* operand shall be either a *symbolic_mode* expression or a non-negative octal integer. The *symbolic_mode* form is described by the grammar later in this section.

Each **clause** shall specify an operation to be performed on the current file mode bits of each *file*. The operations shall be performed on each *file* in the order in which the **clause**s are specified.

The **who** symbols **u**, **g**, and **o** shall specify the *user*, *group*, and *other* parts of the file mode bits, respectively. A **who** consisting of the symbol **a** shall be equivalent to **ugo**.

The **perm** symbols **r**, **w**, and **x** represent the *read*, *write*, and *execute/search* portions of file mode bits, respectively. The **perm** symbol **s** shall represent the *set-user-ID-on-execution* (when **who** contains or implies **u**) and *set-group-ID-on-execution* (when **who** contains or implies **g**) bits.

The **perm** symbol **X** shall represent the execute/search portion of the file mode bits if the file is a directory or if the current (unmodified) file mode bits have at least one of the execute bits (S_IXUSR, S_IXGRP, or S_IXOTH) set. It shall be ignored if the file is not a directory and none of the execute bits are set in the current file mode bits.

The **permcopy** symbols **u**, **g**, and **o** shall represent the current permissions associated with the user, group, and other parts of the file mode bits, respectively. For the remainder of this section, **perm** refers to the non-terminals **perm** and **permcopy** in the grammar.

If multiple **actionlist**s are grouped with a single **wholist** in the grammar, each **actionlist** shall be applied in the order specified with that **wholist**. The *op* symbols shall represent the operation performed, as follows:

\+ If **perm** is not specified, the `'+'` operation shall not change the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

\− If **perm** is not specified, the `'-'` operation shall not change the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be cleared.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be cleared.

= Clear the file mode bits specified by the **who** value, or, if no **who** value is specified, all of the file mode bits specified in this volume of POSIX.1-2017.

If **perm** is not specified, the '=' operation shall make no further modifications to the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

When using the symbolic mode form on a regular file, it is implementation-defined whether or not:

Requests to set the set-user-ID-on-execution or set-group-ID-on-execution bit when all execute bits are currently clear and none are being set are ignored.

Requests to clear all execute bits also clear the set-user-ID-on-execution and set-group-ID-on-execution bits.

Requests to clear the set-user-ID-on-execution or set-group-ID-on-execution bits when all execute bits are currently clear are ignored. However, if the command *ls* **–l** *file* writes an *s* in the position indicating that the set-user-ID-on-execution or set-group-ID-on-execution is set, the commands *chmod* **u–s** *file* or *chmod* **g–s** *file*, respectively, shall not be ignored.

When using the symbolic mode form on other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

If the **who** symbol **o** is used in conjunction with the **perm** symbol **s** with no other **who** symbols being specified, the set-user-ID-on-execution and set-group-ID-on-execution bits shall not be modified. It shall not be an error to specify the **who** symbol **o** in conjunction with the **perm** symbol **s**.

XSI The **perm** symbol **t** shall specify the S_ISVTX bit. When used with a file of type directory, it can be used with the **who** symbol **a**, or with no **who** symbol. It shall not be an error to specify a **who** symbol of **u**, **g**, or **o** in conjunction with the **perm** symbol **t**, but the meaning of these combinations is unspecified. The effect when using the **perm** symbol **t** with any file type other than directory is unspecified.

For an octal integer *mode* operand, the file mode bits shall be set absolutely.

For each bit set in the octal number, the corresponding file permission bit shown in the following table shall be set; all other file permission bits shall be cleared. For regular files, for each bit set in the octal number corresponding to the set-user-ID-on-execution or the set-group-ID-on-execution, bits shown in the following table shall be set; if these bits are not set in the octal number, they are cleared. For other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

Octal	Mode Bit	Octal	Mode Bit	Octal	Mode Bit	Octal	Mode Bit
4000	S_ISUID	**0400**	S_IRUSR	**0040**	S_IRGRP	**0004**	S_IROTH
2000	S_ISGID	**0200**	S_IWUSR	**0020**	S_IWGRP	**0002**	S_IWOTH
XSI **1000**	S_ISVTX	**0100**	S_IXUSR	**0010**	S_IXGRP	**0001**	S_IXOTH

When bits are set in the octal number other than those listed in the table above, the behavior is unspecified.

Grammar for chmod

The grammar and lexical conventions in this section describe the syntax for the *symbolic_mode* operand. The general conventions for this style of grammar are described in Section 1.3 (on page 2335). A valid *symbolic_mode* can be represented as the non-terminal symbol *symbolic_mode* in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

The lexical processing is based entirely on single characters. Implementations need not allow <blank> characters within the single argument being processed.

```
%start    symbolic_mode
%%

symbolic_mode    : clause
                 | symbolic_mode ',' clause
                 ;

clause           : actionlist
                 | wholist actionlist
                 ;

wholist          : who
                 | wholist who
                 ;

who              : 'u' | 'g' | 'o' | 'a'
                 ;

actionlist       : action
                 | actionlist action
                 ;

action           : op
                 | op permlist
                 | op permcopy
                 ;

permcopy         : 'u' | 'g' | 'o'
                 ;

op               : '+' | '-' | '='
                 ;

permlist         : perm
                 | perm permlist
                 ;

XSI  perm        : 'r' | 'w' | 'x' | 'X' | 's' | 't'
                 ;
```

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Some implementations of the *chmod* utility change the mode of a directory before the files in the directory when performing a recursive (**–R** option) change; others change the directory mode after the files in the directory. If an application tries to remove read or search permission for a file hierarchy, the removal attempt fails if the directory is changed first; on the other hand, trying to re-enable permissions to a restricted hierarchy fails if directories are changed last. Users should not try to make a hierarchy inaccessible to themselves.

Some implementations of *chmod* never used the *umask* of the process when changing modes; systems conformant with this volume of POSIX.1-2017 do so when **who** is not specified. Note the difference between:

```
chmod a–w file
```

which removes all write permissions, and:

```
chmod –– –w file
```

which removes write permissions that would be allowed if **file** was created with the same *umask*.

Conforming applications should never assume that they know how the set-user-ID and set-group-ID bits on directories are interpreted.

EXAMPLES

Mode	Results
a+=	Equivalent to *a*+,*a*=; clears all file mode bits.
go+–w	Equivalent to *go*+,*go*–*w*; clears group and other write bits.
g=*o*–*w*	Equivalent to *g*=*o*,*g*–*w*; sets group bit to match other bits and then clears group write bit.
g–*r*+*w*	Equivalent to *g*–*r*,*g*+*w*; clears group read bit and sets group write bit.
uo=*g*	Sets owner bits to match group bits and sets other bits to match group bits.

RATIONALE

The functionality of *chmod* is described substantially through references to concepts defined in the System Interfaces volume of POSIX.1-2017. In this way, there is less duplication of effort required for describing the interactions of permissions. However, the behavior of this utility is not described in terms of the *chmod*( ) function from the System Interfaces volume of POSIX.1-2017 because that specification requires certain side-effects upon alternate file access control mechanisms that might not be appropriate, depending on the implementation.

Implementations that support mandatory file and record locking as specified by the 1984 /usr/group standard historically used the combination of set-group-ID bit set and group execute bit clear to indicate mandatory locking. This condition is usually set or cleared with the symbolic mode **perm** symbol **l** instead of the **perm** symbols **s** and **x** so that the mandatory locking mode is not changed without explicit indication that that was what the user intended. Therefore, the details on how the implementation treats these conditions must be defined in the documentation. This volume of POSIX.1-2017 does not require mandatory locking (nor does the System Interfaces volume of POSIX.1-2017), but does allow it as an extension. However, this volume of POSIX.1-2017 does require that the *ls* and *chmod* utilities work consistently in this

area. If *ls* **–l** *file* indicates that the set-group-ID bit is set, *chmod* **g–s** *file* must clear it (assuming appropriate privileges exist to change modes).

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. This problem is avoided here by specifying only 0 and >0 as exit values.

The System Interfaces volume of POSIX.1-2017 indicates that implementation-defined restrictions may cause the S_ISUID and S_ISGID bits to be ignored. This volume of POSIX.1-2017 allows the *chmod* utility to choose to modify these bits before calling *chmod*( ) (or some function providing equivalent capabilities) for non-regular files. Among other things, this allows implementations that use the set-user-ID and set-group-ID bits on directories to enable extended features to handle these extensions in an intelligent manner.

The **X perm** symbol was adopted from BSD-based systems because it provides commonly desired functionality when doing recursive (**–R** option) modifications. Similar functionality is not provided by the *find* utility. Historical BSD versions of *chmod*, however, only supported **X** with *op*+; it has been extended in this volume of POSIX.1-2017 because it is also useful with *op*=. (It has also been added for *op*– even though it duplicates **x**, in this case, because it is intuitive and easier to explain.)

The grammar was extended with the *permcopy* non-terminal to allow historical-practice forms of symbolic modes like **o=u –g** (that is, set the ``other'' permissions to the permissions of ``owner'' minus the permissions of ``group'').

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

> Octal modes have been kept and made mandatory despite being marked obsolescent in the ISO POSIX-2: 1993 standard.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to ``Default.''.

The Open Group Base Resolution bwg2001-010 is applied, adding the description of the S_ISVTX bit and the **t perm** symbol as part of the XSI option.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/16 is applied, changing the XSI shaded text in the EXTENDED DESCRIPTION from:

> ``The **perm** symbol **t** shall specify the S_ISVTX bit and shall apply to directories only. The effect when using it with any other file type is unspecified. It can be used with the **who** symbols **o**, **a**, or with no **who** symbol. It shall not be an error to specify a **who** symbol of **u** or **g** in conjunction with the **perm** symbol **t**; it shall be ignored for **u** and **g**.''

to:

> ``The **perm** symbol **t** shall specify the S_ISVTX bit. When used with a file of type directory, it can be used with the **who** symbol **a**, or with no **who** symbol. It shall not be an error to specify a **who** symbol of **u**, **g**, or **o** in conjunction with the **perm** symbol **t**, but the meaning of these combinations is unspecified. The effect when using the **perm** symbol **t** with any file type other than directory is unspecified.''

This change is to permit historical behavior.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #130 is applied, adding text to the DESCRIPTION about about marking for update the last file status change timestamp of the file.

NAME

chown ‡'change the file ownership

SYNOPSIS

```
chown [-h] owner[:group] file...
chown -R [-H|-L|-P] owner[:group] file...
```

DESCRIPTION

The *chown* utility shall set the user ID of the file named by each *file* operand to the user ID specified by the *owner* operand.

For each *file* operand, or, if the **-R** option is used, each file encountered while walking the directory trees specified by the *file* operands, the *chown* utility shall perform actions equivalent to the *chown*() function defined in the System Interfaces volume of POSIX.1-2017, called with the following arguments:

1. The *file* operand shall be used as the *path* argument.
2. The user ID indicated by the *owner* portion of the first operand shall be used as the *owner* argument.
3. If the *group* portion of the first operand is given, the group ID indicated by it shall be used as the *group* argument; otherwise, the group ownership shall not be changed.

Unless *chown* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chown* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

-h For each file operand that names a file of type symbolic link, *chown* shall attempt to set the user ID of the symbolic link. If a group ID was specified, for each file operand that names a file of type symbolic link, *chown* shall attempt to set the group ID of the symbolic link.

-H If the **-R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chown* shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

-L If the **-R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chown* shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

-P If the **-R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chown* shall change the owner ID (and group ID, if specified) of the symbolic link. The *chown* utility shall not follow the symbolic link to any other part of the file hierarchy.

-R Recursively change file user and group IDs. For each *file* operand that names a directory, *chown* shall change the user ID (and group ID, if specified) of the directory and all files in the file hierarchy below it. Unless a **-H**, **-L**, or **-P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **-H**, **-L**, and **-P** shall not be

considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

owner[:*group*] A user ID and optional group ID to be assigned to *file*. The *owner* portion of this operand shall be a user name from the user database or a numeric user ID. Either specifies a user ID which shall be given to each file named by one of the *file* operands. If a numeric *owner* operand exists in the user database as a user name, the user ID number associated with that user name shall be used as the user ID. Similarly, if the *group* portion of this operand is present, it shall be a group name from the group database or a numeric group ID. Either specifies a group ID which shall be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name shall be used as the group ID.

file A pathname of a file whose user ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chown*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of *chown* to a user with appropriate privileges.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. These are masked by specifying only 0 and >0 as exit values.

The functionality of *chown* is described substantially through references to functions in the System Interfaces volume of POSIX.1-2017. In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

The 4.3 BSD method of specifying both owner and group was included in this volume of POSIX.1-2017 because:

> There are cases where the desired end condition could not be achieved using the *chgrp* and *chown* (that only changed the user ID) utilities. (If the current owner is not a member of the desired group and the desired owner is not a member of the current group, the *chown*( ) function could fail unless both owner and group are changed at the same time.)
>
> Even if they could be changed independently, in cases where both are being changed, there is a 100% performance penalty caused by being forced to invoke both utilities.

The BSD syntax *user*[.*group*] was changed to *user*[:*group*] in this volume of POSIX.1-2017 because the <period> is a valid character in login names (as specified by the Base Definitions volume of POSIX.1-2017, login names consist of characters in the portable filename character set). The <colon> character was chosen as the replacement for the <period> character because it would never be allowed as a character in a user name or group name on historical implementations.

The **−R** option is considered by some observers as an undesirable departure from the historical UNIX system tools approach; since a tool, *find*, already exists to recurse over directories, there seemed to be no good reason to require other tools to have to duplicate that functionality. However, the **−R** option was deemed an important user convenience, is far more efficient than forking a separate process for each element of the directory hierarchy, and is in widespread historical use.

FUTURE DIRECTIONS

None.

XSH *chown*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

New options **–h**, **–H**, **–L**, and **–P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to ``Default.''.

The ``otherwise, ...'' text in item 3. of the DESCRIPTION is changed to ``otherwise, the group ownership shall not be changed''.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/17 is applied, changing the SYNOPSIS to make it clear that **–h** and **–R** are optional.

Issue 7

SD5-XCU-ERN-9 is applied, removing the **–R** from the first line of the SYNOPSIS.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The description of the **–h** and **–P** options is revised.

NAME

cksum ‡'write file checksums and sizes

SYNOPSIS

```
cksum [file...]
```

DESCRIPTION

The *cksum* utility shall calculate and write to standard output a cyclic redundancy check (CRC) for each input file, and also write to standard output the number of octets in each file. The CRC used is based on the polynomial used for CRC error checking in the ISO/IEC 8802-3:1996 standard (Ethernet).

The encoding for the CRC checksum is defined by the generating polynomial:

$$G(x)=x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

Mathematically, the CRC value corresponding to a given file shall be defined by the following procedure:

1. The n bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These n bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer shall be used.
2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31.
3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.
4. The bit sequence is complemented and the result is the CRC.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be checked. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cksum*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

83805 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
83806 characters (for example, single-byte as opposed to multi-byte characters in
83807 arguments).

83808 *LC_MESSAGES*
83809 Determine the locale that should be used to affect the format and contents of
83810 diagnostic messages written to standard error.

83811 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

83812 **ASYNCHRONOUS EVENTS**
83813 Default.

83814 **STDOUT**
83815 For each file processed successfully, the *cksum* utility shall write in the following format:

83816 `"%u %d %s\n", <checksum>, <# of octets>, <pathname>`

83817 If no *file* operand was specified, the pathname and its leading <space> shall be omitted.

83818 **STDERR**
83819 The standard error shall be used only for diagnostic messages.

83820 **OUTPUT FILES**
83821 None.

83822 **EXTENDED DESCRIPTION**
83823 None.

83824 **EXIT STATUS**
83825 The following exit values shall be returned:

83826 0 All files were processed successfully.

83827 >0 An error occurred.

83828 **CONSEQUENCES OF ERRORS**
83829 Default.

83830 **APPLICATION USAGE**
83831 The *cksum* utility is typically used to quickly compare a suspect file against a trusted version of
83832 the same, such as to ensure that files transmitted over noisy media arrive intact. However, this
83833 comparison cannot be considered cryptographically secure. The chances of a damaged file
83834 producing the same CRC as the original are small; deliberate deception is difficult, but probably
83835 not impossible.

83836 Although input files to *cksum* can be any type, the results need not be what would be expected
83837 on character special device files or on file types not described by the System Interfaces volume of
83838 POSIX.1-2017. Since this volume of POSIX.1-2017 does not specify the block size used when
83839 doing input, checksums of character special files need not process all of the data in those files.

83840 The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted
83841 between two systems and undergoes any data transformation (such as changing little-endian
83842 byte ordering to big-endian), identical CRC values cannot be expected. Implementations
83843 performing such transformations may extend *cksum* to handle such situations.

83844 **EXAMPLES**
83845 None.

RATIONALE

The following C-language program can be used as a model to describe the algorithm. It assumes that a **char** is one octet. It also assumes that the entire file is available for one pass through the function. This was done for simplicity in demonstrating the algorithm, rather than as an implementation model.

    register unsigned c, s = 0;

    for (i = n; i > 0; --i) {
        c = *b++;
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
    }

    /* Extend with the length of the string. */
    while (n != 0) {
        c = n & 0377;
        n >>= 8;
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
    }

    return ~s;
}
```

The historical practice of writing the number of ``blocks'' has been changed to writing the number of octets, since the latter is not only more useful, but also since historical implementations have not been consistent in defining what a ``block'' meant.

The algorithm used was selected to increase the operational robustness of *cksum*. Neither the System V nor BSD *sum* algorithm was selected. Since each of these was different and each was the default behavior on those systems, no realistic compromise was available if either were selected—some set of historical applications would break. Therefore, the name was changed to *cksum*. Although the historical *sum* commands will probably continue to be provided for many years, programs designed for portability across systems should use the new name.

The algorithm selected is based on that used by the ISO/IEC 8802-3: 1996 standard (Ethernet) for the frame check sequence field. The algorithm used does not match the technical definition of a *checksum*; the term is used for historical reasons. The length of the file is included in the CRC calculation because this parallels inclusion of a length field by Ethernet in its CRC, but also because it guards against inadvertent collisions between files that begin with different series of zero octets. The chance that two different files produce identical CRCs is much greater when their lengths are not considered. Keeping the length and the checksum of the file itself separate would yield a slightly more robust algorithm, but historical usage has always been that a single number (the checksum as printed) represents the signature of the file. It was decided that historical usage was the more important consideration.

Early proposals contained modifications to the Ethernet algorithm that involved extracting table values whenever an intermediate result became zero. This was demonstrated to be less robust than the current method and mathematically difficult to describe or justify.

The calculation used is identical to that given in pseudo-code in the referenced Sarwate article. The pseudo-code rendition is:

```
X <- 0; Y <- 0;
for i <- m -1 step -1 until 0 do
    begin
    T <- X(1) ^ A[i];
    X(1) <- X(0); X(0) <- Y(1); Y(1) <- Y(0); Y(0) <- 0;
    comment: f[T] and f'[T] denote the T-th words in the
        table f and f' ;
    X <- X ^ f[T]; Y <- Y ^ f'[T];
    end
```

The pseudo-code is reproduced exactly as given; however, note that in the case of *cksum*, **A[i]** represents a byte of the file, the words **X** and **Y** are treated as a single 32-bit value, and the tables **f** and **f′** are a single table containing 32-bit values.

The referenced Sarwate article also discusses generating the table.

FUTURE DIRECTIONS

None.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0081 [446] is applied.

NAME

cmp ‡'compare two files

SYNOPSIS

```
cmp [-l|-s] file1 file2
```

DESCRIPTION

The *cmp* utility shall compare two files. The *cmp* utility shall write no output if the files are the same. Under default options, if they differ, it shall write to standard output the byte and line number at which the first difference occurred. Bytes and lines shall be numbered beginning with 1.

OPTIONS

The *cmp* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-l (Lowercase ell.) Write the byte number (decimal) and the differing bytes (octal) for each difference.

-s Write nothing to standard output or standard error when files differ; indicate differing files through exit status only. It is unspecified whether a diagnostic message is written to standard error when an error is encountered; if a message is not written, the error is indicated through exit status only.

OPERANDS

The following operands shall be supported:

file1 A pathname of the first file to be compared. If *file1* is `'-'`, the standard input shall be used.

file2 A pathname of the second file to be compared. If *file2* is `'-'`, the standard input shall be used.

If both *file1* and *file2* refer to standard input or refer to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if the *file1* or *file2* operand refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cmp*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to

standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In the POSIX locale, results of the comparison shall be written to standard output. When no options are used, the format shall be:

```
"%s %s differ: char %d, line %d\n", file1, file2,
    <byte number>, <line number>
```

When the **–l** option is used, the format shall be:

```
"%d %o %o\n", <byte number>, <differing byte>,
    <differing byte>
```

for each byte that differs. The first <*differing byte*> number is from *file1* while the second is from *file2*. In both cases, <*byte number*> shall be relative to the beginning of the file, beginning with 1.

No output shall be written to standard output when the **–s** option is used.

STDERR

The standard error shall be used only for diagnostic messages. If the **–l** option is used and *file1* and *file2* differ in length, or if the **–s** option is not used and *file1* and *file2* are identical for the entire length of the shorter file, in the POSIX locale the following diagnostic message shall be written:

```
"cmp: EOF on %s%s\n", <name of shorter file>, <additional info>
```

The <*additional info*> field shall either be null or a string that starts with a <blank> and contains no <newline> characters. Some implementations report on the number of lines in this case.

If the **–s** option is used and an error occurs, it is unspecified whether a diagnostic message is written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The files are identical.

1 The files are different; this includes the case where one file is identical to the first part of the other.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Although input files to *cmp* can be any type, the results might not be what would be expected on character special device files or on file types not described by the System Interfaces volume of POSIX.1-2017. Since this volume of POSIX.1-2017 does not specify the block size used when doing input, comparisons of character special files need not compare all of the data in those files.

For files which are not text files, line numbers simply reflect the presence of a <newline>, without any implication that the file is organized into lines.

Since the behavior of **−s** differs between implementations as to whether error messages are written, the only way to ensure consistent behavior of *cmp* when **−s** is used is to redirect standard error to **/dev/null**.

If error messages are wanted, instead of using **−s** standard output should be redirected to **/dev/null**, and anything written to standard error should be discarded if the exit status is 1. For example:

```
silent_cmp() {
    # compare files with no output except error messages
    message=$(cmp "$@" 2>&1 >/dev/null)
    status=$?
    case $status in
    (0|1) ;;
    (*) printf '%s\n' "$message" ;;
    esac
    return $status
}
```

EXAMPLES

None.

RATIONALE

The global language in Section 1.4 (on page 2336) indicates that using two mutually-exclusive options together produces unspecified results. Some System V implementations consider the option usage:

```
cmp −l −s ...
```

to be an error. They also treat:

```
cmp −s −l ...
```

as if no options were specified. Both of these behaviors are considered bugs, but are allowed.

The word **char** in the standard output format comes from historical usage, even though it is actually a byte number. When *cmp* is supported in other locales, implementations are encouraged to use the word *byte* or its equivalent in another language. Users should not interpret this difference to indicate that the functionality of the utility changed between locales.

Some implementations report on the number of lines in the identical-but-shorter file case. This is allowed by the inclusion of the *<additional info>* fields in the output format. The restriction on having a leading <blank> and no <newline> characters is to make parsing for the filename easier. It is recognized that some filenames containing white-space characters make parsing difficult anyway, but the restriction does aid programs used on systems where the names are predominantly well behaved.

FUTURE DIRECTIONS

Future versions of this standard may require that diagnostic messages are written to standard error when the **–s** option is specified.

NAME

comm — select or reject lines common to two files

SYNOPSIS

```
comm [-123] file1 file2
```

DESCRIPTION

The *comm* utility shall read *file1* and *file2*, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in *file1*, lines only in *file2*, and lines in both files.

If the lines in both files are not ordered according to the collating sequence of the current locale, the results are unspecified.

If the collating sequence of the current locale does not have a total ordering of all characters (see XBD Section 7.3.2, on page 147) and any lines from the input files collate equally but are not identical, *comm* should treat them as different lines but may treat them as being the same. If it treats them as different, *comm* should expect them to be ordered according to a further byte-by-byte comparison using the collating sequence for the POSIX locale and if they are not ordered in this way, the output of *comm* can identify such lines as being both unique to *file1* and unique to *file2* instead of being in both files.

OPTIONS

The *comm* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-1 Suppress the output column of lines unique to *file1*.

-2 Suppress the output column of lines unique to *file2*.

-3 Suppress the output column of lines duplicated in *file1* and *file2*.

OPERANDS

The following operands shall be supported:

file1 A pathname of the first file to be compared. If *file1* is `'-'`, the standard input shall be used.

file2 A pathname of the second file to be compared. If *file2* is `'-'`, the standard input shall be used.

If both *file1* and *file2* refer to standard input or to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if one of the *file1* or *file2* operands refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *comm*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

84149 *LC_ALL* If set to a non-empty string value, override the values of all the other
84150 internationalization variables.

84151 *LC_COLLATE*
84152 Determine the locale for the collating sequence *comm* expects to have been used
84153 when the input files were sorted.

84154 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
84155 characters (for example, single-byte as opposed to multi-byte characters in
84156 arguments and input files).

84157 *LC_MESSAGES*
84158 Determine the locale that should be used to affect the format and contents of
84159 diagnostic messages written to standard error.

84160 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

84161 **ASYNCHRONOUS EVENTS**
84162 Default.

84163 **STDOUT**
84164 The *comm* utility shall produce output depending on the options selected. If the **–1**, **–2**, and **–3**
84165 options are all selected, *comm* shall write nothing to standard output.

84166 If the **–1** option is not selected, lines contained only in *file1* shall be written using the format:

84167 `"%s\n", <line in file1>`

84168 If the **–2** option is not selected, lines contained only in *file2* are written using the format:

84169 `"%s%s\n", <lead>, <line in file2>`

84170 where the string <*lead*> is as follows:

84171 <tab> The **–1** option is not selected.

84172 null string The **–1** option is selected.

84173 If the **–3** option is not selected, lines contained in both files shall be written using the format:

84174 `"%s%s\n", <lead>, <line in both>`

84175 where the string <*lead*> is as follows:

84176 <tab><tab> Neither the **–1** nor the **–2** option is selected.

84177 <tab> Exactly one of the **–1** and **–2** options is selected.

84178 null string Both the **–1** and **–2** options are selected.

84179 If the input files were ordered according to the collating sequence of the current locale, the lines
84180 written shall be in the collating sequence of the current locale. If the input files contained any
84181 lines that collated equally but were not identical and within each file those lines were ordered
84182 according to a further byte-by-byte comparison using the collating sequence for the POSIX
84183 locale, and *comm* treated them as different lines, then lines written that collate equally but are not
84184 identical should be ordered according to a further byte-by-byte comparison using the collating
84185 sequence for the POSIX locale.

84186 **STDERR**
84187 The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were successfully output as specified.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the input files are not properly presorted, the output of *comm* might not be useful.

When using *comm* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

If the collating sequence of the current locale does not have a total ordering of all characters, this can affect the behavior of *comm* in the following ways:

> If *comm* treats lines as being the same only if they are identical, some lines can be misleadingly identified as being both unique to *file1* and unique to *file2*.
>
> If *comm* treats lines as being the same if they collate equally and a line from *file1* collates equally with a line from *file2* but is not identical to it, one of the lines is misleadingly identified as being in both files and the other is not written to the output at all.

Such problems can be avoided by forcing the use of the POSIX locale; for example, the following identifies lines in both *file1* and *file2*:

```
LC_ALL=POSIX sort file1 > file1.posix
LC_ALL=POSIX sort file2 > file2.posix
LC_ALL=POSIX comm -12 file1.posix file2.posix | sort
```

The final *sort* re-sorts the output of *comm* according to the collating sequence of the original locale. Doing this might be difficult if more than one column is output and leading <blank>s cannot be ignored.

EXAMPLES

If a file named **xcu** contains a sorted list of the utilities in this volume of POSIX.1-2017, a file named **xpg3** contains a sorted list of the utilities specified in the X/Open Portability Guide, Issue 3, and a file named **svid89** contains a sorted list of the utilities in the System V Interface Definition Third Edition:

```
comm -23 xcu xpg3 | comm -23 - svid89
```

would print a list of utilities in this volume of POSIX.1-2017 not specified by either of the other documents:

```
comm -12 xcu xpg3 | comm -12 - svid89
```

would print a list of utilities specified by all three documents, and:

```
comm -12 xpg3 svid89 | comm -23 - xcu
```

would print a list of utilities specified by both XPG3 and the SVID, but not specified in this volume of POSIX.1-2017.

RATIONALE

None.

FUTURE DIRECTIONS

A future version of this standard may require that if any lines from the input files collate equally but are not identical, then *comm* treats them as different lines and expects them to be ordered according to a further byte-by-byte comparison using the collating sequence for the POSIX locale.

A future version of this standard may require that if the input files contained any lines that collated equally but were not identical and within each file those lines were ordered according to a further byte-by-byte comparison using the collating sequence for the POSIX locale, then lines written that collate equally but are not identical are ordered according to a further byte-by-byte comparison using the collating sequence for the POSIX locale.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0076 [963], XCU/TC2-2008/0077 [663], and XCU/TC2-2008/0078 [963] are applied.

NAME

command ‡'execute a simple command

SYNOPSIS

```
command [-p] command_name [argument...]
command [-p][-v|-V] command_name
```

DESCRIPTION

The *command* utility shall cause the shell to treat the arguments as a simple command, suppressing the shell function lookup that is described in Section 2.9.1.1 (on page 2367), item 1b.

If the *command_name* is the same as the name of one of the special built-in utilities, the special properties in the enumerated list at the beginning of Section 2.14 (on page 2384) shall not occur. In every other respect, if *command_name* is not the name of a function, the effect of *command* (with no options) shall be the same as omitting *command*.

When the **−v** or **−V** option is used, the *command* utility shall provide information concerning how a command name is interpreted by the shell.

OPTIONS

The *command* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−p Perform the command search using a default value for *PATH* that is guaranteed to find all of the standard utilities.

−v Write a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment (see Section 2.12, on page 2381), to invoke *command_name*, but do not invoke *command_name*.

Utilities, regular built-in utilities, *command_name*s including a <slash> character, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1, on page 2367), shall be written as absolute pathnames.

Shell functions, special built-in utilities, regular built-in utilities not associated with a *PATH* search, and shell reserved words shall be written as just their names.

An alias shall be written as a command line that represents its alias definition.

Otherwise, no output shall be written and the exit status shall reflect that the name was not found.

−V Write a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment (see Section 2.12, on page 2381), but do not invoke *command_name*. Although the format of this string is unspecified, it shall indicate in which of the following categories *command_name* falls and shall include the information stated:

Utilities, regular built-in utilities, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1, on page 2367), shall be identified as such and include the absolute pathname in the string.

Other shell functions shall be identified as functions.

Aliases shall be identified as aliases and their definitions included in the string.

Special built-in utilities shall be identified as special built-in utilities.

Regular built-in utilities not associated with a *PATH* search shall be identified as regular built-in utilities. (The term ``regular'' need not be used.)

Shell reserved words shall be identified as reserved words.

OPERANDS

The following operands shall be supported:

argument One of the strings treated as an argument to *command_name*.

command_name
The name of a utility or a special built-in utility.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *command*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path used during the command search described in Section 2.9.1.1 (on page 2367), except as described under the **−p** option.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **−v** option is specified, standard output shall be formatted as:

```
"%s\n", <pathname or command>
```

When the **−V** option is specified, standard output shall be formatted as:

```
"%s\n", <unspecified>
```

84338 **STDERR**

84339 The standard error shall be used only for diagnostic messages.

84340 **OUTPUT FILES**

84341 None.

84342 **EXTENDED DESCRIPTION**

84343 None.

84344 **EXIT STATUS**

84345 When the **−v** or **−V** options are specified, the following exit values shall be returned:

84346 0 Successful completion.

84347 >0 The *command_name* could not be found or an error occurred.

84348 Otherwise, the following exit values shall be returned:

84349 126 The utility specified by *command_name* was found but could not be invoked.

84350 127 An error occurred in the *command* utility or the utility specified by *command_name* could not
84351 be found.

84352 Otherwise, the exit status of *command* shall be that of the simple command specified by the
84353 arguments to *command*.

84354 **CONSEQUENCES OF ERRORS**

84355 Default.

84356 **APPLICATION USAGE**

84357 The order for command search allows functions to override regular built-ins and path searches.
84358 This utility is necessary to allow functions that have the same name as a utility to call the utility
84359 (instead of a recursive call to the function).

84360 The system default path is available using *getconf*; however, since *getconf* may need to have the
84361 *PATH* set up before it can be called itself, the following can be used:

84362 `command −p getconf PATH`

84363 There are some advantages to suppressing the special characteristics of special built-ins on
84364 occasion. For example:

84365 `command exec > unwritable-file`

84366 does not cause a non-interactive script to abort, so that the output status can be checked by the
84367 script.

84368 The *command*, *env*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an
84369 error occurs so that applications can distinguish ``failure to find a utility'' from ``invoked utility
84370 exited with an error indication''. The value 127 was chosen because it is not commonly used for
84371 other meanings; most utilities use small values for ``normal error conditions'' and the values
84372 above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen
84373 in a similar manner to indicate that the utility could be found, but not invoked. Some scripts
84374 produce meaningful error messages differentiating the 126 and 127 cases. The distinction
84375 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
84376 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for
84377 any other reason.

84378 Since the **−v** and **−V** options of *command* produce output in relation to the current shell execution
84379 environment, *command* is generally provided as a shell regular built-in. If it is called in a subshell
84380 or separate utility execution environment, such as one of the following:

```
(PATH=foo command -v)
 nohup command -v
```

it does not necessarily produce correct results. For example, when called with *nohup* or an *exec* function, in a separate utility execution environment, most implementations are not able to identify aliases, functions, or special built-ins.

Two types of regular built-ins could be encountered on a system and these are described separately by *command*. The description of command search in Section 2.9.1.1 (on page 2367) allows for a standard utility to be implemented as a regular built-in as long as it is found in the appropriate place in a *PATH* search. So, for example, *command* **-v** *true* might yield **/bin/true** or some similar pathname. Other implementation-defined utilities that are not defined by this volume of POSIX.1-2017 might exist only as built-ins and have no pathname associated with them. These produce output identified as (regular) built-ins. Applications encountering these are not able to count on *exec*ing them, using them with *nohup*, overriding them with a different *PATH*, and so on.

EXAMPLES

1. Make a version of *cd* that always prints out the new working directory exactly once:

```
cd() {
    command cd "$@" >/dev/null
    pwd
}
```

2. Start off a ``secure shell script'' in which the script avoids being spoofed by its parent:

```
IFS='
'
#    The preceding value should be <space><tab><newline>.
#    Set IFS to its default value.

\unalias -a
#    Unset all possible aliases.
#    Note that unalias is escaped to prevent an alias
#    being used for unalias.

unset -f command
#    Ensure command is not a user function.

PATH="$(command -p getconf PATH):$PATH"
#    Put on a reliable PATH prefix.

#    ...
```

At this point, given correct permissions on the directories called by *PATH*, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this volume of POSIX.1-2017, but it is not prohibited as an extension. For example, the *ENV* variable precedes the invocation of the script with a user start-up script. Such a script could define functions to spoof the application.

RATIONALE

Since *command* is a regular built-in utility it is always found prior to the *PATH* search.

There is nothing in the description of *command* that implies the command line is parsed any differently from that of any other simple command. For example:

```
command a | b ; c
```

is not parsed in any special way that causes `'|'` or `';'` to be treated other than a pipe operator or <semicolon> or that prevents function lookup on **b** or **c**.

The *command* utility is somewhat similar to the Eighth Edition shell *builtin* command, but since *command* also goes to the file system to search for utilities, the name *builtin* would not be intuitive.

The *command* utility is most likely to be provided as a regular built-in. It is not listed as a special built-in for the following reasons:

> The removal of exportable functions made the special precedence of a special built-in unnecessary.
>
> A special built-in has special properties (see Section 2.14, on page 2384) that were inappropriate for invoking other utilities. For example, two commands such as:
>
> ```
> date > unwritable-file
> ```
>
> ```
> command date > unwritable-file
> ```
>
> would have entirely different results; in a non-interactive script, the former would continue to execute the next command, the latter would abort. Introducing this semantic difference along with suppressing functions was seen to be non-intuitive.

The **−p** option is present because it is useful to be able to ensure a safe path search that finds all the standard utilities. This search might not be identical to the one that occurs through one of the *exec* functions (as defined in the System Interfaces volume of POSIX.1-2017) when *PATH* is unset. At the very least, this feature is required to allow the script to access the correct version of *getconf* so that the value of the default path can be accurately retrieved.

The *command* **−v** and **−V** options were added to satisfy requirements from users that are currently accomplished by three different historical utilities: *type* in the System V shell, *whence* in the KornShell, and *which* in the C shell. Since there is no historical agreement on how and what to accomplish here, the POSIX *command* utility was enhanced and the historical utilities were left unmodified. The C shell *which* merely conducts a path search. The KornShell *whence* is more elaborate ‡in addition to the categories required by POSIX, it also reports on tracked aliases, exported aliases, and undefined functions.

The output format of **−V** was left mostly unspecified because human users are its only audience. Applications should not be written to care about this information; they can use the output of **−v** to differentiate between various types of commands, but the additional information that may be emitted by the more verbose **−V** is not needed and should not be arbitrarily constrained in its verbosity or localization for application parsing reasons.

FUTURE DIRECTIONS

None.

compress — compress data

SYNOPSIS

XSI

```
compress [−fv] [−b bits] [file...]
compress [−cfv] [−b bits] [file]
```

DESCRIPTION

The *compress* utility shall attempt to reduce the size of the named files by using adaptive Lempel-Ziv coding algorithm.

Note: Lempel-Ziv is US Patent 4464650, issued to William Eastman, Abraham Lempel, Jacob Ziv, Martin Cohn on August 7th, 1984, and assigned to Sperry Corporation.

Lempel-Ziv-Welch compression is covered by US Patent 4558302, issued to Terry A. Welch on December 10th, 1985, and assigned to Sperry Corporation.

On systems not supporting adaptive Lempel-Ziv coding algorithm, the input files shall not be changed and an error value greater than two shall be returned. Except when the output is to the standard output, each file shall be replaced by one with the extension **.Z**. If the invoking process has appropriate privileges, the ownership, modes, access time, and modification time of the original file are preserved. If appending the **.Z** to the filename would make the name exceed {NAME_MAX} bytes, the command shall fail. If no files are specified, the standard input shall be compressed to the standard output.

OPTIONS

The *compress* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−b *bits* Specify the maximum number of bits to use in a code. For a conforming application, the *bits* argument shall be:

```
9 <= bits <= 14
```

The implementation may allow *bits* values of greater than 14. The default is 14, 15, or 16.

−c Cause *compress* to write to the standard output; the input file is not changed, and no **.Z** files are created.

−f Force compression of *file*, even if it does not actually reduce the size of the file, or if the corresponding *file***.Z** file already exists. If the **−f** option is not given, and the process is not running in the background, the user is prompted as to whether an existing *file***.Z** file should be overwritten. If the response is affirmative, the existing file will be overwritten.

−v Write the percentage reduction of each file to standard error.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be compressed.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.

INPUT FILES

If *file* operands are specified, the input files contain the data to be compressed.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *compress*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages, prompts, and the output from the **−v** option written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no *file* operands are specified, or if a *file* operand is `'−'`, or if the **−c** option is specified, the standard output contains the compressed output.

STDERR

The standard error shall be used only for diagnostic and prompt messages and the output from **−v**.

OUTPUT FILES

The output files shall contain the compressed output. The format of compressed files is unspecified and interchange of such files between implementations (including access via unspecified file sharing mechanisms) is not required by POSIX.1-2017.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

1 An error occurred.

2 One or more files were not compressed because they would have increased in size (and the **−f** option was not specified).

>2 An error occurred.

CONSEQUENCES OF ERRORS

The input file shall remain unmodified.

APPLICATION USAGE

The amount of compression obtained depends on the size of the input, the number of *bits* per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50-60%. Compression is generally much better than that achieved by Huffman coding or adaptive Huffman coding (*compact*), and takes less time to compute.

Although *compress* strictly follows the default actions upon receipt of a signal or when an error occurs, some unexpected results may occur. In some implementations it is likely that a partially compressed file is left in place, alongside its uncompressed input file. Since the general operation of *compress* is to delete the uncompressed file only after the **.Z** file has been successfully filled, an application should always carefully check the exit status of *compress* before arbitrarily deleting files that have like-named neighbors with **.Z** suffixes.

The limit of 14 on the *bits* option-argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

An error case is added for systems not supporting adaptive Lempel-Ziv coding.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #125 is applied, revising the ENVIRONMENT VARIABLES section.

NAME

cp ‡'copy files

SYNOPSIS

```
cp [−Pfip] source_file target_file
cp [−Pfip] source_file... target
cp −R [−H|−L|−P] [−fip] source_file... target
```

DESCRIPTION

The first synopsis form is denoted by two operands, neither of which are existing files of type directory. The *cp* utility shall copy the contents of *source_file* (or, if *source_file* is a file of type symbolic link, the contents of the file referenced by *source_file*) to the destination path named by *target_file.*

The second synopsis form is denoted by two or more operands where the **−R** option is not specified and the first synopsis form is not applicable. It shall be an error if any *source_file* is a file of type directory, if *target* does not exist, or if *target* does not name a directory. The *cp* utility shall copy the contents of each *source_file* (or, if *source_file* is a file of type symbolic link, the contents of the file referenced by *source_file*) to the destination path named by the concatenation of *target*, a single <slash> character if *target* did not end in a <slash>, and the last component of *source_file*.

The third synopsis form is denoted by two or more operands where the **−R** option is specified. The *cp* utility shall copy each file in the file hierarchy rooted in each *source_file* to a destination path named as follows:

If *target* exists and names an existing directory, the name of the corresponding destination path for each file in the file hierarchy shall be the concatenation of *target*, a single <slash> character if *target* did not end in a <slash>, and the pathname of the file relative to the directory containing *source_file*.

If *target* does not exist and two operands are specified, the name of the corresponding destination path for *source_file* shall be *target*; the name of the corresponding destination path for all other files in the file hierarchy shall be the concatenation of *target*, a <slash> character, and the pathname of the file relative to *source_file*.

It shall be an error if *target* does not exist and more than two operands are specified, or if *target* exists and does not name a directory.

In the following description, the term *dest_file* refers to the file named by the destination path. The term *source_file* refers to the file that is being copied, whether specified as an operand or a file in a file hierarchy rooted in a *source_file* operand. If *source_file* is a file of type symbolic link:

If the **−R** option was not specified, *cp* shall take actions based on the type and contents of the file referenced by the symbolic link, and not by the symbolic link itself, unless the **−P** option was specified.

If the **−R** option was specified:

‡ If none of the options **−H**, **−L**, nor **−P** were specified, it is unspecified which of **−H**, **−L**, or **−P** will be used as a default.

‡ If the **−H** option was specified, *cp* shall take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.

‡ If the **−L** option was specified, *cp* shall take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand or any symbolic links encountered during traversal of a file hierarchy.

If the **−P** option was specified, *cp* shall copy any symbolic link specified as a *source_file* operand and any symbolic links encountered during traversal of a file hierarchy, and shall not follow any symbolic links.

For each *source_file*, the following steps shall be taken:

1. If *source_file* references the same file as *dest_file*, *cp* may write a diagnostic message to standard error; it shall do nothing more with *source_file* and shall go on to any remaining files.
2. If *source_file* is of type directory, the following steps shall be taken:
   a. If the **−R** option was not specified, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.
   b. If *source_file* was not specified as an operand and *source_file* is dot or dot-dot, *cp* shall do nothing more with *source_file* and go on to any remaining files.
   c. If *dest_file* exists and it is a file type not specified by the System Interfaces volume of POSIX.1-2017, the behavior is implementation-defined.
   d. If *dest_file* exists and it is not of type directory, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file* or any files below *source_file* in the file hierarchy, and go on to any remaining files.
   e. If the directory *dest_file* does not exist, it shall be created with file permission bits set to the same value as those of *source_file*, modified by the file creation mask of the user if the **−p** option was not specified, and then bitwise-inclusively OR'ed with S_IRWXU. If *dest_file* cannot be created, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files. It is unspecified if *cp* attempts to copy files in the file hierarchy rooted in *source_file*.
   f. The files in the directory *source_file* shall be copied to the directory *dest_file*, taking the four steps (1 to 4) listed here with the files as *source_file*s.
   g. If *dest_file* was created, its file permission bits shall be changed (if necessary) to be the same as those of *source_file*, modified by the file creation mask of the user if the **−p** option was not specified.
   h. The *cp* utility shall do nothing more with *source_file* and go on to any remaining files.
3. If *source_file* is of type regular file, the following steps shall be taken:
   a. The behavior is unspecified if *dest_file* exists and was written by a previous step. Otherwise, if *dest_file* exists, the following steps shall be taken:
      i. If the **−i** option is in effect, the *cp* utility shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, *cp* shall do nothing more with *source_file* and go on to any remaining files.
      ii. A file descriptor for *dest_file* shall be obtained by performing actions equivalent to the *open*( ) function defined in the System Interfaces volume of POSIX.1-2017 called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_TRUNC as the *oflag* argument.
      iii. If the attempt to obtain a file descriptor fails and the **−f** option is in effect, *cp* shall attempt to remove the file by performing actions equivalent to the *unlink*( ) function defined in the System Interfaces volume of POSIX.1-2017

called using *dest_file* as the *path* argument. If this attempt succeeds, *cp* shall continue with step 3b.

b. If *dest_file* does not exist, a file descriptor shall be obtained by performing actions equivalent to the *open*() function defined in the System Interfaces volume of POSIX.1-2017 called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_CREAT as the *oflag* argument. The file permission bits of *source_file* shall be the *mode* argument.

c. If the attempt to obtain a file descriptor fails, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

d. The contents of *source_file* shall be written to the file descriptor. Any write errors shall cause *cp* to write a diagnostic message to standard error and continue to step 3e.

e. The file descriptor shall be closed.

f. The *cp* utility shall do nothing more with *source_file*. If a write error occurred in step 3d, it is unspecified if *cp* continues with any remaining files. If no write error occurred in step 3d, *cp* shall go on to any remaining files.

4. Otherwise, the **−R** option was specified, and the following steps shall be taken:

a. The *dest_file* shall be created with the same file type as *source_file*.

b. If *source_file* is a file of type FIFO, the file permission bits shall be the same as those of *source_file,* modified by the file creation mask of the user if the **−p** option was not specified. Otherwise, the permissions, owner ID, and group ID of *dest_file* are implementation-defined.

If this creation fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

c. If *source_file* is a file of type symbolic link, and the options require the symbolic link itself to be acted upon, the pathname contained in *dest_file* shall be the same as the pathname contained in *source_file*.

If this fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

If the implementation provides additional or alternate access control mechanisms (see XBD Section 4.5, on page 108), their effect on copies of files is implementation-defined.

OPTIONS

The *cp* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−f If a file descriptor for a destination file cannot be obtained, as described in step 3.a.ii., attempt to unlink the destination file and proceed.

−H Take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.

−i Write a prompt to standard error before copying to any existing non-directory destination file. If the response from the standard input is affirmative, the copy shall be attempted; otherwise, it shall not.

84722 **−L** Take actions based on the type and contents of the file referenced by any symbolic
84723 link specified as a *source_file* operand or any symbolic links encountered during
84724 traversal of a file hierarchy.

84725 **−P** Take actions on any symbolic link specified as a *source_file* operand or any
84726 symbolic link encountered during traversal of a file hierarchy.

84727 **−p** Duplicate the following characteristics of each source file in the corresponding
84728 destination file:

84729 1. The time of last data modification and time of last access. If this duplication
84730 fails for any reason, *cp* shall write a diagnostic message to standard error.

84731 2. The user ID and group ID. If this duplication fails for any reason, it is
84732 unspecified whether *cp* writes a diagnostic message to standard error.

84733 3. The file permission bits and the S_ISUID and S_ISGID bits. Other,
84734 implementation-defined, bits may be duplicated as well. If this duplication
84735 fails for any reason, *cp* shall write a diagnostic message to standard error.

84736 If the user ID or the group ID cannot be duplicated, the file permission bits
84737 S_ISUID and S_ISGID shall be cleared. If these bits are present in the source file but
84738 are not duplicated in the destination file, it is unspecified whether *cp* writes a
84739 diagnostic message to standard error.

84740 The order in which the preceding characteristics are duplicated is unspecified. The
84741 *dest_file* shall not be deleted if these characteristics cannot be preserved.

84742 **−R** Copy file hierarchies.

84743 Specifying more than one of the mutually-exclusive options **−H**, **−L**, and **−P** shall not be
84744 considered an error. The last option specified shall determine the behavior of the utility.

84745 **OPERANDS**

84746 The following operands shall be supported:

84747 *source_file* A pathname of a file to be copied. If a *source_file* operand is `'−'`, it shall refer to a
84748 file named −; implementations shall not treat it as meaning standard input.

84749 *target_file* A pathname of an existing or nonexistent file, used for the output when a single
84750 file is copied. If a *target_file* operand is `'−'`, it shall refer to a file named −;
84751 implementations shall not treat it as meaning standard output.

84752 *target* A pathname of a directory to contain the copied files.

84753 **STDIN**

84754 The standard input shall be used to read an input line in response to each prompt specified in
84755 the STDERR section. Otherwise, the standard input shall not be used.

84756 **INPUT FILES**

84757 The input files specified as operands may be of any file type.

84758 **ENVIRONMENT VARIABLES**

84759 The following environment variables shall affect the execution of *cp*:

84760 *LANG* Provide a default value for the internationalization variables that are unset or null.
84761 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
84762 variables used to determine the values of locale categories.)

84763 *LC_ALL* If set to a non-empty string value, override the values of all the other
84764 internationalization variables.

84765 *LC_COLLATE*
84766 Determine the locale for the behavior of ranges, equivalence classes, and multi-
84767 character collating elements used in the extended regular expression defined for
84768 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

84769 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
84770 characters (for example, single-byte as opposed to multi-byte characters in
84771 arguments and input files) and the behavior of character classes used in the
84772 extended regular expression defined for the **yesexpr** locale keyword in the
84773 *LC_MESSAGES* category.

84774 *LC_MESSAGES*
84775 Determine the locale used to process affirmative responses, and the locale used to
84776 affect the format and contents of diagnostic messages and prompts written to
84777 standard error.

84778 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

84779 **ASYNCHRONOUS EVENTS**
84780 Default.

84781 **STDOUT**
84782 Not used.

84783 **STDERR**
84784 A prompt shall be written to standard error under the conditions specified in the DESCRIPTION
84785 section. The prompt shall contain the destination pathname, but its format is otherwise
84786 unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

84787 **OUTPUT FILES**
84788 The output files may be of any type.

84789 **EXTENDED DESCRIPTION**
84790 None.

84791 **EXIT STATUS**
84792 The following exit values shall be returned:

84793 0 All files were copied successfully.

84794 >0 An error occurred.

84795 **CONSEQUENCES OF ERRORS**
84796 If *cp* is prematurely terminated by a signal or error, files or file hierarchies may be only partially
84797 copied and files and directories may have incorrect permissions or access and modification
84798 times.

APPLICATION USAGE

The set-user-ID and set-group-ID bits are explicitly cleared when files are created. This is to prevent users from creating programs that are set-user-ID or set-group-ID to them when copying files or to make set-user-ID or set-group-ID files accessible to new groups of users. For example, if a file is set-user-ID and the copy has a different group ID than the source, a new group of users has execute permission to a set-user-ID program than did previously. In particular, this is a problem for superusers copying users' trees.

EXAMPLES

None.

RATIONALE

The **−i** option exists on BSD systems, giving applications and users a way to avoid accidentally removing files when copying. Although the 4.3 BSD version does not prompt if the standard input is not a terminal, the standard developers decided that use of **−i** is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds on standard input.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application using the **−i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The **−p** option is historical practice on BSD systems, duplicating the time of last data modification and time of last access. This volume of POSIX.1-2017 extends it to preserve the user and group IDs, as well as the file permissions. This requirement has obvious problems in that the directories are almost certainly modified after being copied. This volume of POSIX.1-2017 requires that the modification times be preserved. The statement that the order in which the characteristics are duplicated is unspecified is to permit implementations to provide the maximum amount of security for the user. Implementations should take into account the obvious security issues involved in setting the owner, group, and mode in the wrong order or creating files with an owner, group, or mode different from the final value.

It is unspecified whether *cp* writes diagnostic messages when the user and group IDs cannot be set due to the widespread practice of users using **−p** to duplicate some portion of the file characteristics, indifferent to the duplication of others. Historic implementations only write diagnostic messages on errors other than [EPERM].

Earlier versions of this standard included support for the **−r** option to copy file hierarchies. The **−r** option is historical practice on BSD and BSD-derived systems. This option is no longer specified by POSIX.1-2017 but may be present in some implementations. The **−R** option was added as a close synonym to the **−r** option, selected for consistency with all other options in this volume of POSIX.1-2017 that do recursive directory descent.

The difference between **−R** and the removed **−r** option is in the treatment by *cp* of file types other than regular and directory. It was implementation-defined how the − option treated special files to allow both historical implementations and those that chose to support **−r** with the same abilities as **−R** defined by this volume of POSIX.1-2017. The original **−r** flag, for historic reasons, did not handle special files any differently from regular files, but always read the file and copied its contents. This had obvious problems in the presence of special file types; for example, character devices, FIFOs, and sockets.

When a failure occurs during the copying of a file hierarchy, *cp* is required to attempt to copy files that are on the same level in the hierarchy or above the file where the failure occurred. It is unspecified if *cp* shall attempt to copy files below the file where the failure occurred (which

cannot succeed in any case).

Permissions, owners, and groups of created special file types have been deliberately left as implementation-defined. This is to allow systems to satisfy special requirements (for example, allowing users to create character special devices, but requiring them to be owned by a certain group). In general, it is strongly suggested that the permissions, owner, and group be the same as if the user had run the historical *mknod*, *ln*, or other utility to create the file. It is also probable that additional privileges are required to create block, character, or other implementation-defined special file types.

Additionally, the −**p** option explicitly requires that all set-user-ID and set-group-ID permissions be discarded if any of the owner or group IDs cannot be set. This is to keep users from unintentionally giving away special privilege when copying programs.

When creating regular files, historical versions of *cp* use the mode of the source file as modified by the file mode creation mask. Other choices would have been to use the mode of the source file unmodified by the creation mask or to use the same mode as would be given to a new file created by the user (plus the execution bits of the source file) and then modify it by the file mode creation mask. In the absence of any strong reason to change historic practice, it was in large part retained.

When creating directories, historical versions of *cp* use the mode of the source directory, plus read, write, and search bits for the owner, as modified by the file mode creation mask. This is done so that *cp* can copy trees where the user has read permission, but the owner does not. A side-effect is that if the file creation mask denies the owner permissions, *cp* fails. Also, once the copy is done, historical versions of *cp* set the permissions on the created directory to be the same as the source directory, unmodified by the file creation mask.

This behavior has been modified so that *cp* is always able to create the contents of the directory, regardless of the file creation mask. After the copy is done, the permissions are set to be the same as the source directory, as modified by the file creation mask. This latter change from historical behavior is to prevent users from accidentally creating directories with permissions beyond those they would normally set and for consistency with the behavior of *cp* in creating files.

It is not a requirement that *cp* detect attempts to copy a file to itself; however, implementations are strongly encouraged to do so. Historical implementations have detected the attempt in most cases.

There are two methods of copying subtrees in this volume of POSIX.1-2017. The other method is described as part of the *pax* utility (see *pax*). Both methods are historical practice. The *cp* utility provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy, while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

The wording allowing *cp* to copy a directory to implementation-defined file types not specified by the System Interfaces volume of POSIX.1-2017 is provided so that implementations supporting symbolic links are not required to prohibit copying directories to symbolic links. Other extensions to the System Interfaces volume of POSIX.1-2017 file types may need to use this loophole as well.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The **−r** option is marked obsolescent.

The new options **−H**, **−L**, and **−P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 #194 is applied, adding a description of the **−P** option.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/18 is applied, correcting an error in the SEE ALSO section.

Issue 7

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

Austin Group Interpretations 1003.1-2001 #092, #164, #165, and #168 are applied.

SD5-XCU-ERN-31 and SD5-XCU-ERN-42 are applied, updating the DESCRIPTION.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-102 is applied, clarifying the **−i** option within the OPTIONS section.

The obsolescent **−r** option is removed.

The **−P** option is added to the SYNOPSIS and to the DESCRIPTION with respect to the **−R** option.

NAME

crontab — schedule periodic background work

SYNOPSIS

```
crontab [file]
UP  crontab [-e|-l|-r]
```

DESCRIPTION

UP The *crontab* utility shall create, replace, or edit a user's crontab entry; a crontab entry is a list of commands and the times at which they shall be executed. The new crontab entry can be input by UP specifying *file* or input from standard input if no *file* operand is specified, or by using an editor, if **−e** is specified.

Upon execution of a command from a crontab entry, the implementation shall supply a default environment, defining at least the following environment variables:

HOME A pathname of the user's home directory.

LOGNAME The user's login name.

PATH A string representing a search path guaranteed to find all of the standard utilities.

SHELL A pathname of the command interpreter. When *crontab* is invoked as specified by this volume of POSIX.1-2017, the value shall be a pathname for *sh*.

The values of these variables when *crontab* is invoked as specified by this volume of POSIX.1-2017 shall not affect the default values provided when the scheduled command is run.

If standard output and standard error are not redirected by commands executed from the crontab entry, any generated output or errors shall be mailed, via an implementation-defined method, to the user.

XSI Users shall be permitted to use *crontab* if their names appear in the file **cron.allow** which is located in an implementation-defined directory. If that file does not exist, the file **cron.deny**, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to *crontab*. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only **cron.deny** exists and is empty, global usage shall be permitted. The **cron.allow** and **cron.deny** files shall consist of one user name per line.

OPTIONS

The *crontab* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

UP **−e** Edit a copy of the invoking user's crontab entry, or create an empty entry to edit if the crontab entry does not exist. When editing is complete, the entry shall be installed as the user's crontab entry.

−l (The letter ell.) List the invoking user's crontab entry.

−r Remove the invoking user's crontab entry.

OPERANDS

The following operand shall be supported:

file The pathname of a file that contains specifications, in the format defined in the INPUT FILES section, for crontab entries.

84956 **STDIN**

84957 See the INPUT FILES section.

84958 **INPUT FILES**

84959 In the POSIX locale, the user or application shall ensure that a crontab entry is a text file
84960 consisting of lines of six fields each. The fields shall be separated by <blank> characters. The
84961 first five fields shall be integer patterns that specify the following:

84962 1. Minute [0,59]
84963 2. Hour [0,23]
84964 3. Day of the month [1,31]
84965 4. Month of the year [1,12]
84966 5. Day of the week ([0,6] with 0=Sunday)

84967 Each of these patterns can be either an <asterisk> (meaning all valid values), an element, or a list
84968 of elements separated by <comma> characters. An element shall be either a number or two
84969 numbers separated by a <hyphen-minus> (meaning an inclusive range). The specification of
84970 days can be made by two fields (day of the month and day of the week). If month, day of month,
84971 and day of week are all <asterisk> characters, every day shall be matched. If either the month or
84972 day of month is specified as an element or list, but the day of week is an <asterisk>, the month
84973 and day of month fields shall specify the days that match. If both month and day of month are
84974 specified as an <asterisk>, but day of week is an element or list, then only the specified days of
84975 the week match. Finally, if either the month or day of month is specified as an element or list,
84976 and the day of week is also specified as an element or list, then any day matching either the
84977 month and day of month, or the day of week, shall be matched.

84978 The sixth field of a line in a crontab entry is a string that shall be executed by *sh* at the specified
84979 times. A <percent-sign> character in this field shall be translated to a <newline>. Any character
84980 preceded by a <backslash> (including the `'%'`) shall cause that character to be treated literally.
84981 Only the first line (up to a `'%'` or end-of-line) of the command field shall be executed by the
84982 command interpreter. The other lines shall be made available to the command as standard input.

84983 Blank lines and those whose first non-<blank> is `'#'` shall be ignored.

84984 XSI The text files **cron.allow** and **cron.deny**, which are located in an implementation-defined
84985 directory, shall contain zero or more user names, one per line, of users who are, respectively,
84986 authorized or denied access to the service underlying the *crontab* utility.

84987 **ENVIRONMENT VARIABLES**

84988 The following environment variables shall affect the execution of *crontab*:

84989 *EDITOR* Determine the editor to be invoked when the **−e** option is specified. The default
84990 editor shall be *vi*.

84991 *LANG* Provide a default value for the internationalization variables that are unset or null.
84992 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
84993 variables used to determine the values of locale categories.)

84994 *LC_ALL* If set to a non-empty string value, override the values of all the other
84995 internationalization variables.

84996 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
84997 characters (for example, single-byte as opposed to multi-byte characters in
84998 arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
If the **–l** option is specified, the crontab entry shall be written to the standard output.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
UP The user's crontab entry is not submitted, removed, edited, or listed.

APPLICATION USAGE
The format of the crontab entry shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

The default settings of the *HOME*, *LOGNAME*, *PATH*, and *SHELL* variables that are given to the scheduled job are not affected by the settings of those variables when *crontab* is run; as stated, they are defaults. The text about ``invoked as specified by this volume of POSIX.1-2017'' means that the implementation may provide extensions that allow these variables to be affected at runtime, but that the user has to take explicit action in order to access the extension, such as give a new option flag or modify the format of the crontab entry.

A typical user error is to type only *crontab*; this causes the system to wait for the new crontab entry on standard input. If end-of-file is typed (generally <control>-D), the crontab entry is replaced by an empty file. In this case, the user should type the interrupt character, which prevents the crontab entry from being replaced.

EXAMPLES

1. Clean up **core** files every weekday morning at 3:15 am:

```
15 3 * * 1–5 find "$HOME" –name core –exec rm –f {} + 2>/dev/null
```

2. Mail a birthday greeting:

```
0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.
```

3. As an example of specifying the two types of days:

```
0 0 1,15 * 1
```

would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to `'*'`; for example:

```
0 0 * * 1
```

would run a command only on Mondays.

RATIONALE

All references to a *cron* daemon and to *cron files* have been omitted. Although historical implementations have used this arrangement, there is no reason to limit future implementations.

This description of *crontab* is designed to support only users with normal privileges. The format of the input is based on the System V *crontab*; however, there is no requirement here that the actual system database used by the *cron* daemon (or a similar mechanism) use this format internally. For example, systems derived from BSD are likely to have an additional field appended that indicates the user identity to be used when the job is submitted.

The **−e** option was adopted from the SVID as a user convenience, although it does not exist in all historical implementations.

FUTURE DIRECTIONS

None.

SEE ALSO

at

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

The *crontab* utility (except for the **−e** option) is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the *crontab* utility.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The first example is changed to remove the unreliable use of *find* | *xargs*.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0079 [584] is applied.

NAME

csplit ‡'split files based on context

SYNOPSIS

```
csplit [-ks] [-f prefix] [-n number] file arg...
```

DESCRIPTION

The *csplit* utility shall read the file named by the *file* operand, write all or part of that file into other files as directed by the *arg* operands, and write the sizes of the files.

OPTIONS

The *csplit* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-f *prefix* Name the created files *prefix***00**, *prefix***01**, ..., *prefix**n*. The default is **xx00** ... **xx***n*. If the *prefix* argument would create a filename exceeding {NAME_MAX} bytes, an error shall result, *csplit* shall exit with a diagnostic message, and no files shall be created.

-k Leave previously created files intact. By default, *csplit* shall remove created files if an error occurs.

-n *number* Use *number* decimal digits to form filenames for the file pieces. The default shall be 2.

-s Suppress the output of file size messages.

OPERANDS

The following operands shall be supported:

file The pathname of a text file to be split. If *file* is `'-'`, the standard input shall be used.

Each *arg* operand can be one of the following:

*/rexp/***[***offset***]**

A file shall be created using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with *offset*, if any, applied. The regular expression *rexp* shall follow the rules for basic regular expressions described in XBD Section 9.3 (on page 183). The application shall use the sequence `"\/"` to specify a <slash> character within the *rexp*. The optional offset shall be a positive or negative integer value representing a number of lines. A positive integer value can be preceded by `'+'`. If the selection of lines from an *offset* expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line shall be set to the line that results from the evaluation of the regular expression with any offset applied. If the current line is the first line in the file and a regular expression operation has not yet been performed, the pattern match of *rexp* shall be applied from the current line to the end of the file. Otherwise, the pattern match of *rexp* shall be applied from the line following the current line to the end of the file.

*%rexp%***[***offset***]**

Equivalent to */rexp/***[***offset***]**, except that no file shall be created for the selected section of the input file. The application shall use the sequence `"\%"` to specify a <percent-sign> character within the *rexp*.

85117 *line_no* Create a file from the current line up to (but not including) the line number *line_no*.
85118 Lines in the file shall be numbered starting at one. The current line becomes
85119 *line_no*.

85120 {*num*} Repeat operand. This operand can follow any of the operands described
85121 previously. If it follows a *rexp* type operand, that operand shall be applied *num*
85122 more times. If it follows a *line_no* operand, the file shall be split every *line_no* lines,
85123 *num* times, from that point.

85124 An error shall be reported if an operand does not reference a line between the current position
85125 and the end of the file.

85126 **STDIN**

85127 See the INPUT FILES section.

85128 **INPUT FILES**

85129 The input file shall be a text file.

85130 **ENVIRONMENT VARIABLES**

85131 The following environment variables shall affect the execution of *csplit*:

85132 *LANG* Provide a default value for the internationalization variables that are unset or null.
85133 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
85134 variables used to determine the values of locale categories.)

85135 *LC_ALL* If set to a non-empty string value, override the values of all the other
85136 internationalization variables.

85137 *LC_COLLATE*
85138 Determine the locale for the behavior of ranges, equivalence classes, and multi-
85139 character collating elements within regular expressions.

85140 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
85141 characters (for example, single-byte as opposed to multi-byte characters in
85142 arguments and input files) and the behavior of character classes within regular
85143 expressions.

85144 *LC_MESSAGES*
85145 Determine the locale that should be used to affect the format and contents of
85146 diagnostic messages written to standard error.

85147 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

85148 **ASYNCHRONOUS EVENTS**

85149 If the **–k** option is specified, created files shall be retained. Otherwise, the default action occurs.

85150 **STDOUT**

85151 Unless the **–s** option is used, the standard output shall consist of one line per file created, with a
85152 format as follows:

85153 `"%d\n", <file size in bytes>`

85154 **STDERR**

85155 The standard error shall be used only for diagnostic messages.

85156 **OUTPUT FILES**

85157 The output files shall contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

By default, created files shall be removed if an error occurs. When the **−k** option is specified, created files shall not be removed if an error occurs.

APPLICATION USAGE

None.

EXAMPLES

1. This example creates four files, **cobol00** . . . **cobol03**:

   ```
   csplit −f cobol file '/procedure division/' /par5./ /par16./
   ```

   After editing the split files, they can be recombined as follows:

   ```
   cat cobol0[0−3] > file
   ```

   Note that this example overwrites the original file.

2. This example would split the file after the first 99 lines, and every 100 lines thereafter, up to 9 999 lines; this is because lines in the file are numbered from 1 rather than zero, for historical reasons:

   ```
   csplit −k file  100  {99}
   ```

3. Assuming that **prog.c** follows the C-language coding convention of ending routines with a `'}'` at the beginning of the line, this example creates a file containing each separate C routine (up to 21) in **prog.c**:

   ```
   csplit −k prog.c '%main(%'  '/^}/+1' {20}
   ```

RATIONALE

The **−n** option was added to extend the range of filenames that could be handled.

Consideration was given to adding a **−a** flag to use the alphabetic filename generation used by the historical *split* utility, but the functionality added by the **−n** option was deemed to make alphabetic naming unnecessary.

FUTURE DIRECTIONS

None.

SEE ALSO

sed, *split*

XBD Chapter 8 (on page 173), Section 9.3 (on page 183), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The description of regular expression operands is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

The *csplit* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The SYNOPSIS and OPERANDS sections are revised to use a single *arg* to split a file into two pieces.

NAME

ctags — create a tags file (**DEVELOPMENT**, **FORTRAN**)

SYNOPSIS

SD

```
ctags [−a] [−f tagsfile] pathname...

ctags −x pathname...
```

DESCRIPTION

The *ctags* utility shall be provided on systems that support the the Software Development Utilities option, and either or both of the C-Language Development Utilities option and FORTRAN Development Utilities option. On other systems, it is optional.

The *ctags* utility shall write a *tagsfile* or an index of objects from C-language or FORTRAN source files specified by the *pathname* operands. The *tagsfile* shall list the locators of language-specific objects within the source files. A locator consists of a name, pathname, and either a search pattern or a line number that can be used in searching for the object definition. The objects that shall be recognized are specified in the EXTENDED DESCRIPTION section.

OPTIONS

The *ctags* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−a Append to *tagsfile*.

−f *tagsfile* Write the object locator lists into *tagsfile* instead of the default file named **tags** in the current directory.

−x Produce a list of object names, the line number, and filename in which each is defined, as well as the text of that line, and write this to the standard output. A *tagsfile* shall not be created when **−x** is specified.

OPERANDS

The following *pathname* operands are supported:

*file***.c** Files with basenames ending with the **.c** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.

*file***.h** Files with basenames ending with the **.h** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.

*file***.f** Files with basenames ending with the **.f** suffix shall be treated as FORTRAN-language source code. Such files that are not valid input to *fort77* produce unspecified results.

The handling of other files is implementation-defined.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be text files containing source code in the language indicated by the operand filename suffixes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ctags*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the order in which output is sorted for the **–x** option. The POSIX locale determines the order in which the *tagsfile* is written.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). When processing C-language source code, if the locale is not compatible with the C locale described by the ISO C standard, the results are unspecified.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The list of object name information produced by the **–x** option shall be written to standard output in the following format:

```
"%s %d %s %s", <object-name>, <line-number>, <filename>, <text>
```

where <*text*> is the text of line <*line-number*> of file <*filename*>.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

When the **–x** option is not specified, the format of the output file shall be:

```
"%s\t%s\t/%s/\n", <identifier>, <filename>, <pattern>
```

where <*pattern*> is a search pattern that could be used by an editor to find the defining instance of <*identifier*> in <*filename*> (where *defining instance* is indicated by the declarations listed in the EXTENDED DESCRIPTION).

An optional <circumflex> (`'^'`) can be added as a prefix to <*pattern*>, and an optional <dollar-sign> can be appended to <*pattern*> to indicate that the pattern is anchored to the beginning (end) of a line of text. Any <slash> or <backslash> characters in <*pattern*> shall be preceded by a <backslash> character. The anchoring <circumflex>, <dollar-sign>, and escaping <backslash> characters shall not be considered part of the search pattern. All other characters in the search pattern shall be considered literal characters.

An alternative format is:

`"%s\t%s\t?%s?\n", <identifier>, <filename>, <pattern>`

which is identical to the first format except that <slash> characters in <*pattern*> shall not be preceded by escaping <backslash> characters, and <question-mark> characters in <*pattern*> shall be preceded by <backslash> characters.

A second alternative format is:

`"%s\t%s\t%d\n", <identifier>, <filename>, <lineno>`

where <*lineno*> is a decimal line number that could be used by an editor to find <*identifier*> in <*filename*>.

Neither alternative format shall be produced by *ctags* when it is used as described by POSIX.1-2017, but the standard utilities that process tags files shall be able to process those formats as well as the first format.

In any of these formats, the file shall be sorted by identifier, based on the collation sequence in the POSIX locale.

EXTENDED DESCRIPTION

If the operand identifies C-language source, the *ctags* utility shall attempt to produce an output line for each of the following objects:

- Function definitions
- Type definitions
- Macros with arguments

It may also produce output for any of the following objects:

- Function prototypes
- Structures
- Unions
- Global variable definitions
- Enumeration types
- Macros without arguments
- **#define** statements
- **#line** statements

Any **#if** and **#ifdef** statements shall produce no output. The tag **main** is treated specially in C programs. The tag formed shall be created by prefixing **M** to the name of the file, with the trailing **.c**, and leading pathname components (if any) removed.

On systems that do not support the C-Language Development Utilities option, *ctags* produces unspecified results for C-language source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

If the operand identifies FORTRAN source, the *ctags* utility shall produce an output line for each function definition. It may also produce output for any of the following objects:

- Subroutine definitions

85325 COMMON statements

85326 PARAMETER statements

85327 DATA and BLOCK DATA statements

85328 Statement numbers

85329 On systems that do not support the FORTRAN Development Utilities option, *ctags* produces
85330 unspecified results for FORTRAN source code files. It should write to standard error a message
85331 identifying this condition and cause a non-zero exit status to be produced.

85332 It is implementation-defined what other objects (including duplicate identifiers) produce output.

85333 **EXIT STATUS**

85334 The following exit values shall be returned:

85335 0 Successful completion.

85336 >0 An error occurred.

85337 **CONSEQUENCES OF ERRORS**

85338 Default.

85339 **APPLICATION USAGE**

85340 The output with −**x** is meant to be a simple index that can be written out as an off-line readable
85341 function index. If the input files to *ctags* (such as **.c** files) were not created using the same locale
85342 as that in effect when *ctags* −**x** is run, results might not be as expected.

85343 The description of C-language processing says ``attempts to'' because the C language can be
85344 greatly confused, especially through the use of **#define**s, and this utility would be of no use if
85345 the real C preprocessor were run to identify them. The output from *ctags* may be fooled and
85346 incorrect for various constructs.

85347 **EXAMPLES**

85348 None.

85349 **RATIONALE**

85350 The option list was significantly reduced from that provided by historical implementations. The
85351 −**F** option was omitted as redundant, since it is the default. The −**B** option was omitted as being
85352 of very limited usefulness. The −**t** option was omitted since the recognition of **typedef**s is now
85353 required for C source files. The −**u** option was omitted because the update function was judged
85354 to be not only inefficient, but also rarely needed.

85355 An early proposal included a −**w** option to suppress warning diagnostics. Since the types of such
85356 diagnostics could not be described, the option was omitted as being not useful.

85357 The text for *LC_CTYPE* about compatibility with the C locale acknowledges that the ISO C
85358 standard imposes requirements on the locale used to process C source. This could easily be a
85359 superset of that known as ``the C locale'' by way of implementation extensions, or one of a few
85360 alternative locales for systems supporting different codesets. No statement is made for
85361 FORTRAN because the ANSI X3.9-1978 standard (FORTRAN 77) does not (yet) define a similar
85362 locale concept. However, a general rule in this volume of POSIX.1-2017 is that any time that
85363 locales do not match (preparing a file for one locale and processing it in another), the results are
85364 suspect.

85365 The collation sequence of the tags file is not affected by *LC_COLLATE* because it is typically not
85366 used by human readers, but only by programs such as *vi* to locate the tag within the source files.
85367 Using the POSIX locale eliminates some of the problems of coordinating locales between the
85368 *ctags* file creator and the *vi* file reader.

Historically, the tags file has been used only by *ex* and *vi*. However, the format of the tags file has been published to encourage other programs to use the tags in new ways. The format allows either patterns or line numbers to find the identifiers because the historical *vi* recognizes either. The *ctags* utility does not produce the format using line numbers because it is not useful following any source file changes that add or delete lines. The documented search patterns match historical practice. It should be noted that literal leading <circumflex> or trailing <dollar-sign> characters in the search pattern will only behave correctly if anchored to the beginning of the line or end of the line by an additional <circumflex> or <dollar-sign> character.

Historical implementations also understand the objects used by the languages Pascal and sometimes LISP, and they understand the C source output by *lex* and *yacc*. The *ctags* utility is not required to accommodate these languages, although implementors are encouraged to do so.

The following historical option was not specified, as *vgrind* is not included in this volume of POSIX.1-2017:

−v If the **−v** flag is given, an index of the form expected by *vgrind* is produced on the standard output. This listing contains the function name, filename, and page number (assuming 64-line pages). Since the output is sorted into lexicographic order, it may be desired to run the output through *sort* **−f**. Sample use:

```
ctags −v files | sort −f > index vgrind −x index
```

The special treatment of the tag **main** makes the use of *ctags* practical in directories with more than one program.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The OUTPUT FILES section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE PASC Interpretation 1003.2 #168 is applied, changing ``create'' to ``write'' in the DESCRIPTION.

Issue 7

The *ctags* utility is no longer dependent on support for the User Portability Utilities option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

85407 **NAME**

85408 cut ‡'cut out selected fields of each line of a file

85409 **SYNOPSIS**

85410 `cut –b` *list* `[–n] [`*file*`...]`

85411 `cut –c` *list* `[`*file*`...]`

85412 `cut –f` *list* `[–d` *delim*`] [–s] [`*file*`...]`

85413 **DESCRIPTION**

85414 The *cut* utility shall cut out bytes (**–b** option), characters (**–c** option), or character-delimited fields
85415 (**–f** option) from each line in one or more files, concatenate them, and write them to standard
85416 output.

85417 **OPTIONS**

85418 The *cut* utility shall conform to XBD Section 12.2 (on page 216).

85419 The application shall ensure that the option-argument *list* (see options **–b**, **–c**, and **–f** below) is a
85420 <comma>-separated list or <blank>-separated list of positive numbers and ranges. Ranges can
85421 be in three forms. The first is two positive numbers separated by a <hyphen-minus> (*low–high*),
85422 which represents all fields from the first number to the second number. The second is a positive
85423 number preceded by a <hyphen-minus> (*–high*), which represents all fields from field number 1
85424 to that number. The third is a positive number followed by a <hyphen-minus> (*low–*), which
85425 represents that number to the last field, inclusive. The elements in *list* can be repeated, can
85426 overlap, and can be specified in any order, but the bytes, characters, or fields selected shall be
85427 written in the order of the input data. If an element appears in the selection list more than once,
85428 it shall be written exactly once.

85429 The following options shall be supported:

85430 **–b** *list* Cut based on a *list* of bytes. Each selected byte shall be output unless the **–n** option
85431 is also specified. It shall not be an error to select bytes not present in the input line.

85432 **–c** *list* Cut based on a *list* of characters. Each selected character shall be output. It shall
85433 not be an error to select characters not present in the input line.

85434 **–d** *delim* Set the field delimiter to the character *delim*. The default is the <tab>.

85435 **–f** *list* Cut based on a *list* of fields, assumed to be separated in the file by a delimiter
85436 character (see **–d**). Each selected field shall be output. Output fields shall be
85437 separated by a single occurrence of the field delimiter character. Lines with no field
85438 delimiters shall be passed through intact, unless **–s** is specified. It shall not be an
85439 error to select fields not present in the input line.

85440 **–n** Do not split characters. When specified with the **–b** option, each element in *list* of
85441 the form *low–high* (<hyphen-minus>-separated numbers) shall be modified as
85442 follows:

85443 If the byte selected by *low* is not the first byte of a character, *low* shall be
85444 decremented to select the first byte of the character originally selected by *low*.
85445 If the byte selected by *high* is not the last byte of a character, *high* shall be
85446 decremented to select the last byte of the character prior to the character
85447 originally selected by *high*, or zero if there is no prior character. If the
85448 resulting range element has *high* equal to zero or *low* greater than *high*, the list
85449 element shall be dropped from *list* for that input line without causing an
85450 error.

85451 Each element in *list* of the form *low–* shall be treated as above with *high* set to the

number of bytes in the current line, not including the terminating <newline>. Each element in *list* of the form *–high* shall be treated as above with *low* set to 1. Each element in *list* of the form *num* (a single number) shall be treated as above with *low* set to *num* and *high* set to *num*.

–s Suppress lines with no delimiter characters, when used with the **–f** option. Unless specified, lines with no delimiters shall be passed through untouched.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, or if a *file* operand is `'–'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cut*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *cut* utility output shall be a concatenation of the selected bytes, characters, or fields (one of the following):

```
"%s\n", <concatenation of bytes>
"%s\n", <concatenation of characters>
"%s\n", <concatenation of fields and field delimiters>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *cut* and *fold* utilities can be used to create text files out of files with arbitrary line lengths. The *cut* utility should be used when the number of lines (or records) needs to remain constant. The *fold* utility should be used when the contents of long lines need to be kept contiguous.

Earlier versions of the *cut* utility worked in an environment where bytes and characters were considered equivalent (modulo <backspace> and <tab> processing in some implementations). In the extended world of multi-byte characters, the new **−b** option has been added. The **−n** option (used with **−b**) allows it to be used to act on bytes rounded to character boundaries. The algorithm specified for **−n** guarantees that:

```
cut −b 1−500 −n file > file1
cut −b 501− −n file > file2
```

ends up with all the characters in **file** appearing exactly once in **file1** or **file2**. (There is, however, a <newline> in both **file1** and **file2** for each <newline> in **file**.)

EXAMPLES

Examples of the option qualifier list:

1,4,7 Select the first, fourth, and seventh bytes, characters, or fields and field delimiters.

1−3,8 Equivalent to 1,2,3,8.

−5,10 Equivalent to 1,2,3,4,5,10.

3− Equivalent to third to last, inclusive.

The *low*−*high* forms are not always equivalent when used with **−b** and **−n** and multi-byte characters; see the description of **−n**.

The following command:

```
cut −d : −f 1,6 /etc/passwd
```

reads the System V password file (user database) and produces lines of the form:

```
<user ID>:<home directory>
```

Most utilities in this volume of POSIX.1-2017 work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if **file** contains long lines:

```
cut −b 1−500 −n file > file1
cut −b 501− −n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline>) and **file2** that contains the remainder of the data from **file**. (Note that **file2** is not a text file if there are lines in **file** that are longer than 500 + {LINE_MAX} bytes.) The original file can be recreated from **file1** and **file2** using the command:

```
paste -d "\0" file1 file2 > file
```

RATIONALE

Some historical implementations do not count <backspace> characters in determining character counts with the **-c** option. This may be useful for using *cut* for processing *nroff* output. It was deliberately decided not to have the **-c** option treat either <backspace> or <tab> characters in any special fashion. The *fold* utility does treat these characters specially.

Unlike other utilities, some historical implementations of *cut* exit after not finding an input file, rather than continuing to process the remaining *file* operands. This behavior is prohibited by this volume of POSIX.1-2017, where only the exit status is affected by this problem.

The behavior of *cut* when provided with either mutually-exclusive options or options that do not work logically together has been deliberately left unspecified in favor of global wording in Section 1.4 (on page 2336).

The OPTIONS section was changed in response to IEEE PASC Interpretation 1003.2 #149. The change represents historical practice on all known systems. The original standard was ambiguous on the nature of the output.

The *list* option-arguments are historically used to select the portions of the line to be written, but do not affect the order of the data. For example:

```
echo abcdefghi | cut -c6,2,4-7,1
```

yields `"abdefg"`.

A proposal to enhance *cut* with the following option:

-o Preserve the selected field order. When this option is specified, each byte, character, or field (or ranges of such) shall be written in the order specified by the *list* option-argument, even if this requires multiple outputs of the same bytes, characters, or fields.

was rejected because this type of enhancement is outside the scope of the IEEE P1003.2b draft standard.

FUTURE DIRECTIONS

None.

Issue 6

The OPTIONS section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-171 is applied, adding APPLICATION USAGE.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0080 [584] is applied.

NAME

cxref — generate a C-language program cross-reference table (**DEVELOPMENT**)

SYNOPSIS

XSI
```
cxref [–cs] [–o file] [–w num] [–D name[=def]]... [–I dir]...
    [–U name]... file...
```

DESCRIPTION

The *cxref* utility shall analyze a collection of C-language *file*s and attempt to build a cross-reference table. Information from **#define** lines shall be included in the symbol table. A sorted listing shall be written to standard output of all symbols (auto, static, and global) in each *file* separately, or with the **–c** option, in combination. Each symbol shall contain an <asterisk> before the declaring reference.

OPTIONS

The *cxref* utility shall conform to XBD Section 12.2 (on page 216), except that the order of the **–D**, **–I**, and **–U** options (which are identical to their interpretation by *c99*) is significant. The following options shall be supported:

–c Write a combined cross-reference of all input files.

–s Operate silently; do not print input filenames.

–o *file* Direct output to named *file*.

–w *num* Format output no wider than *num* (decimal) columns. This option defaults to 80 if *num* is not specified or is less than 51.

–D Equivalent to *c99*.

–I Equivalent to *c99*.

–U Equivalent to *c99*.

OPERANDS

The following operand shall be supported:

file A pathname of a C-language source file.

STDIN

Not used.

INPUT FILES

The input files are C-language source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cxref*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the ordering of the output.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

85617 *LC_MESSAGES*
85618 Determine the locale that should be used to affect the format and contents of
85619 diagnostic messages written to standard error.

85620 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

85621 **ASYNCHRONOUS EVENTS**
85622 Default.

85623 **STDOUT**
85624 The standard output shall be used for the cross-reference listing, unless the −**o** option is used to
85625 select a different output file.

85626 The format of standard output is unspecified, except that the following information shall be
85627 included:

85628 If the −**c** option is not specified, each portion of the listing shall start with the name of the
85629 input file on a separate line.

85630 The name line shall be followed by a sorted list of symbols, each with its associated
85631 location pathname, the name of the function in which it appears (if it is not a function
85632 name itself), and line number references.

85633 Each line number may be preceded by an <asterisk> (`'*'`) flag, meaning that this is the
85634 declaring reference. Other single-character flags, with implementation-defined meanings,
85635 may be included.

85636 **STDERR**
85637 The standard error shall be used only for diagnostic messages.

85638 **OUTPUT FILES**
85639 The output file named by the −**o** option shall be used instead of standard output.

85640 **EXTENDED DESCRIPTION**
85641 None.

85642 **EXIT STATUS**
85643 The following exit values shall be returned:

85644 0 Successful completion.

85645 >0 An error occurred.

85646 **CONSEQUENCES OF ERRORS**
85647 Default.

85648 **APPLICATION USAGE**
85649 None.

85650 **EXAMPLES**
85651 None.

85652 **RATIONALE**
85653 None.

85654 **FUTURE DIRECTIONS**
85655 None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the SYNOPSIS, [**−U** *dir*] is changed to [**−U** *name*].

Issue 6

The APPLICATION USAGE section is added.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

85667 **NAME**

85668 date ‡'write the date and time

85669 **SYNOPSIS**

85670 `date [-u] [+format]`

85671 XSI `date [-u] mmddhhmm[[cc]yy]`

85672 **DESCRIPTION**

85673 XSI The *date* utility shall write the date and time to standard output or attempt to set the system
85674 date and time. By default, the current date and time shall be written. If an operand beginning
85675 with '+' is specified, the output format of *date* shall be controlled by the conversion
85676 specifications and other text in the operand.

85677 **OPTIONS**

85678 The *date* utility shall conform to XBD Section 12.2 (on page 216).

85679 The following option shall be supported:

85680 **-u** Perform operations as if the *TZ* environment variable was set to the string "UTC0",
85681 or its equivalent historical value of "GMT0". Otherwise, *date* shall use the timezone
85682 indicated by the *TZ* environment variable or the system default if that variable is
85683 unset or null.

85684 **OPERANDS**

85685 The following operands shall be supported:

85686 *+format* When the format is specified, each conversion specifier shall be replaced in the
85687 standard output by its corresponding value. All other characters shall be copied to
85688 the output without change. The output shall always be terminated with a
85689 <newline>.

85690 **Conversion Specifications**

85691 %a Locale's abbreviated weekday name.

85692 %A Locale's full weekday name.

85693 %b Locale's abbreviated month name.

85694 %B Locale's full month name.

85695 %c Locale's appropriate date and time representation.

85696 %C Century (a year divided by 100 and truncated to an integer) as a decimal
85697 number [00,99].

85698 %d Day of the month as a decimal number [01,31].

85699 %D Date in the format *mm/dd/yy*.

85700 %e Day of the month as a decimal number [1,31] in a two-digit field with
85701 leading <space> character fill.

85702 %h A synonym for %b.

85703 %H Hour (24-hour clock) as a decimal number [00,23].

85704 %I Hour (12-hour clock) as a decimal number [01,12].

85705 `%j` Day of the year as a decimal number [001,366].

85706 `%m` Month as a decimal number [01,12].

85707 `%M` Minute as a decimal number [00,59].

85708 `%n` A <newline>.

85709 `%p` Locale's equivalent of either AM or PM.

85710 `%r` 12-hour clock time [01,12] using the AM/PM notation; in the POSIX
85711 locale, this shall be equivalent to `%I:%M:%S %p`.

85712 `%S` Seconds as a decimal number [00,60].

85713 `%t` A <tab>.

85714 `%T` 24-hour clock time [00,23] in the format *HH*:*MM*:*SS*.

85715 `%u` Weekday as a decimal number [1,7] (1=Monday).

85716 `%U` Week of the year (Sunday as the first day of the week) as a decimal
85717 number [00,53]. All days in a new year preceding the first Sunday shall be
85718 considered to be in week 0.

85719 `%V` Week of the year (Monday as the first day of the week) as a decimal
85720 number [01,53]. If the week containing January 1 has four or more days in
85721 the new year, then it shall be considered week 1; otherwise, it shall be the
85722 last week of the previous year, and the next week shall be week 1.

85723 `%w` Weekday as a decimal number [0,6] (0=Sunday).

85724 `%W` Week of the year (Monday as the first day of the week) as a decimal
85725 number [00,53]. All days in a new year preceding the first Monday shall
85726 be considered to be in week 0.

85727 `%x` Locale's appropriate date representation.

85728 `%X` Locale's appropriate time representation.

85729 `%y` Year within century [00,99].

85730 `%Y` Year with century as a decimal number.

85731 `%Z` Timezone name, or no characters if no timezone is determinable.

85732 `%%` A <percent-sign> character.

85733 See XBD Section 7.3.5 (on page 159) for the conversion specifier values in the
85734 POSIX locale.

85735 **Modified Conversion Specifications**

85736 Some conversion specifiers can be modified by the `E` and `O` modifier characters to
85737 indicate a different format or specification as specified in the *LC_TIME* locale
85738 description (see XBD Section 7.3.5, on page 159). If the corresponding keyword
85739 (see **era**, **era_year**, **era_d_fmt**, and **alt_digits** in XBD Section 7.3.5, on page 159) is
85740 not specified or not supported for the current locale, the unmodified conversion
85741 specifier value shall be used.

85742 `%Ec` Locale's alternative appropriate date and time representation.

`%EC` The name of the base year (period) in the locale's alternative representation.

`%Ex` Locale's alternative date representation.

`%EX` Locale's alternative time representation.

`%Ey` Offset from `%EC` (year only) in the locale's alternative representation.

`%EY` Full alternative year representation.

`%Od` Day of month using the locale's alternative numeric symbols.

`%Oe` Day of month using the locale's alternative numeric symbols.

`%OH` Hour (24-hour clock) using the locale's alternative numeric symbols.

`%OI` Hour (12-hour clock) using the locale's alternative numeric symbols.

`%Om` Month using the locale's alternative numeric symbols.

`%OM` Minutes using the locale's alternative numeric symbols.

`%OS` Seconds using the locale's alternative numeric symbols.

`%Ou` Weekday as a number in the locale's alternative representation (Monday = 1).

`%OU` Week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.

`%OV` Week number of the year (Monday as the first day of the week, rules corresponding to `%V`), using the locale's alternative numeric symbols.

`%Ow` Weekday as a number in the locale's alternative representation (Sunday = 0).

`%OW` Week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.

`%Oy` Year (offset from `%C`) in alternative representation.

XSI *mmddhhmm*[[*cc*]*yy*]

Attempt to set the system date and time from the value given in the operand. This is only possible if the user has appropriate privileges and the system permits the setting of the system date and time. The first *mm* is the month (number); *dd* is the day (number); *hh* is the hour (number, 24-hour system); the second *mm* is the minute (number); *cc* is the century and is the first two digits of the year (this is optional); *yy* is the last two digits of the year and is optional. If century is not specified, then values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive. The current year is the default if *yy* is omitted.

Note: It is expected that in a future version of this standard the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *date*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *date*.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone in which the time and date are written, unless the **−u** option is specified. If the *TZ* variable is unset or null and **−u** is not specified, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When no formatting operand is specified, the output in the POSIX locale shall be equivalent to specifying:

```
date "+%a %b %e %H:%M:%S %Z %Y"
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The date was written successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Conversion specifiers are of unspecified format when not in the POSIX locale. Some of them can contain <newline> characters in some locales, so it may be difficult to use the format shown in standard output for parsing the output of *date* in those locales.

The range of values for `%S` extends from 0 to 60 seconds to accommodate the occasional leap second.

Although certain of the conversion specifiers in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these fields may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The date string formatting capabilities are intended for use in Gregorian-style calendars, possibly with a different starting year (or years). The `%x` and `%c` conversion specifications, however, are intended for local representation; these may be based on a different, non-Gregorian calendar.

The `%C` conversion specification was introduced to allow a fallback for the `%EC` (alternative year format base year); it can be viewed as the base of the current subdivision in the Gregorian calendar. The century number is calculated as the year divided by 100 and truncated to an integer; it should not be confused with the use of ordinal numbers for centuries (for example, ``twenty-first century''.) Both the `%Ey` and `%y` can then be viewed as the offset from `%EC` and `%C`, respectively.

The `E` and `O` modifiers modify the traditional conversion specifiers, so that they can always be used, even if the implementation (or the current locale) does not support the modifier.

The `E` modifier supports alternative date formats, such as the Japanese Emperor's Era, as long as these are based on the Gregorian calendar system. Extending the `E` modifiers to other date elements may provide an implementation-defined extension capable of supporting other calendar systems, especially in combination with the `O` modifier.

The `O` modifier supports time and date formats using the locale's alternative numerical symbols, such as Kanji or Hindi digits or ordinal number representation.

Non-European locales, whether they use Latin digits in computational items or not, often have local forms of the digits for use in date formats. This is not totally unknown even in Europe; a variant of dates uses Roman numerals for the months: the third day of September 1991 would be written as 3.IX.1991. In Japan, Kanji digits are regularly used for dates; in Arabic-speaking countries, Hindi digits are used. The `%d`, `%e`, `%H`, `%I`, `%m`, `%S`, `%U`, `%w`, `%W`, and `%y` conversion specifications always return the date and time field in Latin digits (that is, 0 to 9). The `%O` modifier was introduced to support the use for display purposes of non-Latin digits. In the *LC_TIME* category in *localedef*, the optional **alt_digits** keyword is intended for this purpose. As an example, assume the following (partial) *localedef* source:

```
alt_digits  "";"I";"II";"III";"IV";"V";"VI";"VII";"VIII" \
            "IX";"X";"XI";"XII"
d_fmt       "%e.%Om.%Y"
```

With the above date, the command:

```
date "+%x"
```

would yield 3.IX.1991. With the same **d_fmt**, but without the **alt_digits**, the command would yield 3.9.1991.

EXAMPLES

1. The following are input/output examples of *date* used at arbitrary times in the POSIX locale:

```
$ date
Tue Jun 26 09:58:10 PDT 1990

$ date "+DATE: %m/%d/%y%nTIME: %H:%M:%S"
DATE: 11/02/91
TIME: 13:36:16

$ date "+TIME: %r"
TIME: 01:36:32 PM
```

2. Examples for Denmark, where the default date and time format is `%a %d %b %Y %T %Z`:

```
$ LANG=da_DK.iso_8859-1 date
ons 02 okt 1991 15:03:32 CET

$ LANG=da_DK.iso_8859-1 \
    date "+DATO: %A den %e. %B %Y%nKLOKKEN: %H:%M:%S"
DATO: onsdag den 2. oktober 1991
KLOKKEN: 15:03:56
```

3. Examples for Germany, where the default date and time format is `%a %d.%h.%Y, %T %Z`:

```
$ LANG=De_DE.88591 date
Mi 02.Okt.1991, 15:01:21 MEZ

$ LANG=De_DE.88591 date "+DATUM: %A, %d. %B %Y%nZEIT: %H:%M:%S"
DATUM: Mittwoch, 02. Oktober 1991
ZEIT: 15:02:02
```

4. Examples for France, where the default date and time format is `%a %d %h %Y %Z %T`:

```
$ LANG=Fr_FR.88591 date
Mer 02 oct 1991 MET 15:03:32

$ LANG=Fr_FR.88591 date "+JOUR: %A %d %B %Y%nHEURE: %H:%M:%S"
JOUR: Mercredi 02 octobre 1991
HEURE: 15:03:56
```

RATIONALE

Some of the new options for formatting are from the ISO C standard. The **−u** option was introduced to allow portable access to Coordinated Universal Time (UTC). The string `"GMT0"` is allowed as an equivalent *TZ* value to be compatible with all of the systems using the BSD implementation, where this option originated.

The `%e` format conversion specification (adopted from System V) was added because the ISO C standard conversion specifications did not provide any way to produce the historical default *date* output during the first nine days of any month.

There are two varieties of day and week numbering supported (in addition to any others created with the locale-dependent `%E` and `%O` modifier characters):

> The historical variety in which Sunday is the first day of the week and the weekdays preceding the first Sunday of the year are considered week 0. These are represented by `%w` and `%U`. A variant of this is `%W`, using Monday as the first day of the week, but still referring to week 0. This view of the calendar was retained because so many historical

applications depend on it and the ISO C standard *strftime*( ) function, on which many *date* implementations are based, was defined in this way.

The international standard, based on the ISO 8601: 2004 standard where Monday is the first weekday and the algorithm for the first week number is more complex: If the week (Monday to Sunday) containing January 1 has four or more days in the new year, then it is week 1; otherwise, it is week 53 of the previous year, and the next week is week 1. These are represented by the new conversion specifications `%u` and `%V`, added as a result of international comments.

FUTURE DIRECTIONS

None.

XSH *fprintf*( ), *strftime*( )

CHANGE HISTORY

First released in Issue 2.

Issue 5

Changes are made for Year 2000 alignment.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The `%EX` modified conversion specification is added.

The Open Group Corrigendum U048/2 is applied, correcting the examples.

The DESCRIPTION is updated to refer to conversion specifications, instead of field descriptors for consistency with the *LC_TIME* category.

A clarification is made such that the current year is the default if the *yy* argument is omitted when setting the system date and time.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/19 is applied, correcting the CHANGE HISTORY section.

NAME

dd ‡'convert and copy a file

SYNOPSIS

```
dd [operand...]
```

DESCRIPTION

The *dd* utility shall copy the specified input file to the specified output file with possible conversions using specific input and output block sizes. It shall read the input one block at a time, using the specified input block size; it shall then process the block of data actually returned, which could be smaller than the requested block size. It shall apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size. If the **bs**=*expr* operand is specified and no conversions other than **sync**, **noerror**, or **notrunc** are requested, the data returned from each input block shall be written as a separate output block; if the read returns less than a full block and the **sync** conversion is not specified, the resulting output block shall be the same size as the input block. If the **bs**=*expr* operand is not specified, or a conversion other than **sync**, **noerror**, or **notrunc** is requested, the input shall be processed and collected into full-sized output blocks until the end of the input is reached.

The processing order shall be as follows:

1. An input block is read.
2. If the input block is shorter than the specified input block size and the **sync** conversion is specified, null bytes shall be appended to the input data up to the specified size. (If either **block** or **unblock** is also specified, <space> characters shall be appended instead of null bytes.) The remaining conversions and output shall include the pad characters as if they had been read from the input.
3. If the **bs**=*expr* operand is specified and no conversion other than **sync** or **noerror** is requested, the resulting data shall be written to the output as a single block, and the remaining steps are omitted.
4. If the **swab** conversion is specified, each pair of input data bytes shall be swapped. If there is an odd number of bytes in the input block, the last byte in the input record shall not be swapped.
5. Any remaining conversions (**block**, **unblock**, **lcase**, and **ucase**) shall be performed. These conversions shall operate on the input data independently of the input blocking; an input or output fixed-length record may span block boundaries.
6. The data resulting from input or conversion or both shall be aggregated into output blocks of the specified size. After the end of input is reached, any remaining output shall be written as a block without padding if **conv**=**sync** is not specified; thus, the final output block may be shorter than the output block size.

OPTIONS

None.

OPERANDS

All of the operands shall be processed before any input is read. The following operands shall be supported:

if=*file* Specify the input pathname; the default is standard input.

of=*file* Specify the output pathname; the default is standard output. If the **seek**=*expr* conversion is not also specified, the output file shall be truncated before the copy begins if an explicit **of**=*file* operand is specified, unless **conv**=**notrunc** is specified.

If **seek**=*expr* is specified, but **conv**=**notrunc** is not, the effect of the copy shall be to preserve the blocks in the output file over which *dd* seeks, but no other portion of the output file shall be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file shall be shortened by the copy. If the input file is empty and either the size of the seek is greater than the previous size of the output file or the output file did not previously exist, the size of the output file shall be set to the file offset after the seek.)

ibs=*expr* Specify the input block size, in bytes, by *expr* (default is 512).

obs=*expr* Specify the output block size, in bytes, by *expr* (default is 512).

bs=*expr* Set both input and output block sizes to *expr* bytes, superseding **ibs**= and **obs**=. If no conversion other than **sync**, **noerror**, and **notrunc** is specified, each input block shall be copied to the output as a single block without aggregating short blocks.

cbs=*expr* Specify the conversion block size for **block** and **unblock** in bytes by *expr* (default is zero). If **cbs**= is omitted or given a value of zero, using **block** or **unblock** produces unspecified results.

XSI The application shall ensure that this operand is also specified if the **conv**= operand is specified with a value of **ascii**, **ebcdic**, or **ibm**. For a **conv**= operand with an **ascii** value, the input is handled as described for the **unblock** value, except that characters are converted to ASCII before any trailing <space> characters are deleted. For **conv**= operands with **ebcdic** or **ibm** values, the input is handled as described for the **block** value except that the characters are converted to EBCDIC or IBM EBCDIC, respectively, after any trailing <space> characters are added.

skip=*n* Skip *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation shall read the blocks or seek past them; on non-seekable files, the blocks shall be read and the data shall be discarded.

seek=*n* Skip *n* blocks (using the specified output block size) from the beginning of the output file before copying. On non-seekable files, existing blocks shall be read and space from the current end-of-file to the specified offset, if any, filled with null bytes; on seekable files, the implementation shall seek to the specified offset or read the blocks as described for non-seekable files.

count=*n* Copy only *n* input blocks. If *n* is zero, it is unspecified whether no blocks or all blocks are copied.

conv=*value*[,*value* ...]
Where *value*s are <comma>-separated symbols from the following list:

XSI **ascii** Convert EBCDIC to ASCII; see Table 4-7 (on page 2644).

XSI **ebcdic** Convert ASCII to EBCDIC; see Table 4-7 (on page 2644).

XSI **ibm** Convert ASCII to a different EBCDIC set; see Table 4-8 (on page 2645).

XSI The **ascii**, **ebcdic**, and **ibm** values are mutually-exclusive.

block Treat the input as a sequence of <newline>-terminated or end-of-file-terminated variable-length records independent of the input block boundaries. Each record shall be converted to a record with a fixed length specified by the conversion block size. Any <newline> shall be removed from the input line; <space> characters shall be appended to lines that are shorter than their conversion block size to fill the block.

86026 Lines that are longer than the conversion block size shall be truncated
86027 to the largest number of characters that fit into that size; the number of
86028 truncated lines shall be reported (see the STDERR section).

86029 The **block** and **unblock** values are mutually-exclusive.

86030 **unblock** Convert fixed-length records to variable length. Read a number of bytes
86031 equal to the conversion block size (or the number of bytes remaining in
86032 the input, if less than the conversion block size), delete all trailing
86033 <space> characters, and append a <newline>.

86034 **lcase** Map uppercase characters specified by the *LC_CTYPE* keyword
86035 **tolower** to the corresponding lowercase character. Characters for which
86036 no mapping is specified shall not be modified by this conversion.

86037 The **lcase** and **ucase** symbols are mutually-exclusive.

86038 **ucase** Map lowercase characters specified by the *LC_CTYPE* keyword
86039 **toupper** to the corresponding uppercase character. Characters for
86040 which no mapping is specified shall not be modified by this conversion.

86041 **swab** Swap every pair of input bytes.

86042 **noerror** Do not stop processing on an input error. When an input error occurs, a
86043 diagnostic message shall be written on standard error, followed by the
86044 current input and output block counts in the same format as used at
86045 completion (see the STDERR section). If the **sync** conversion is
86046 specified, the missing input shall be replaced with null bytes and
86047 processed normally; otherwise, the input block shall be omitted from
86048 the output.

86049 **notrunc** Do not truncate the output file. Preserve blocks in the output file not
86050 explicitly written by this invocation of the *dd* utility. (See also the
86051 preceding **of**=*file* operand.)

86052 **sync** Pad every input block to the size of the **ibs**= buffer, appending null
86053 bytes. (If either **block** or **unblock** is also specified, append <space>
86054 characters, rather than null bytes.)

86055 The behavior is unspecified if operands other than **conv**= are specified more than once.

86056 For the **bs**=, **cbs**=, **ibs**=, and **obs**= operands, the application shall supply an expression
86057 specifying a size in bytes. The expression, *expr*, can be:

86058 1. A positive decimal number
86059 2. A positive decimal number followed by *k*, specifying multiplication by 1 024
86060 3. A positive decimal number followed by *b*, specifying multiplication by 512
86061 4. Two or more positive decimal numbers (with or without *k* or *b*) separated by *x*, specifying
86062 the product of the indicated values

86063 All of the operands are processed before any input is read.

86064 XSI The following two tables display the octal number character values used for the **ascii** and **ebcdic**
86065 conversions (first table) and for the **ibm** conversion (second table). In both tables, the ASCII
86066 values are the row and column headers and the EBCDIC values are found at their intersections.
86067 For example, ASCII 0012 (LF) is the second row, third column, yielding 0045 in EBCDIC. The
86068 inverted tables (for EBCDIC to ASCII conversion) are not shown, but are in one-to-one

86069 correspondence with these tables. The differences between the two tables are highlighted by
86070 small boxes drawn around five entries.

86071 **Table 4-7** ASCII to EBCDIC Conversion

86073 **STDIN**

86074 If no **if**= operand is specified, the standard input shall be used. See the INPUT FILES section.

86075 **INPUT FILES**

86076 The input file can be any file type.

86077 **ENVIRONMENT VARIABLES**

86078 The following environment variables shall affect the execution of *dd*:

86079 *LANG* Provide a default value for the internationalization variables that are unset or null.
86080 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
86081 variables used to determine the values of locale categories.)

86082 *LC_ALL* If set to a non-empty string value, override the values of all the other
86083 internationalization variables.

86084 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
86085 characters (for example, single-byte as opposed to multi-byte characters in
86086 arguments and input files), the classification of characters as uppercase or
86087 lowercase, and the mapping of characters from one case to the other.

86088 *LC_MESSAGES*
86089 Determine the locale that should be used to affect the format and contents of
86090 diagnostic messages written to standard error and informative messages written to
86091 standard output.

86092 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

86093 **ASYNCHRONOUS EVENTS**

86094 For SIGINT, the *dd* utility shall interrupt its current processing, write status information to
86095 standard error, and exit as though terminated by SIGINT. It shall take the standard action for all
86096 other signals; see the ASYNCHRONOUS EVENTS section in Section 1.4 (on page 2336).

86097 **STDOUT**

86098 If no **of**= operand is specified, the standard output shall be used. The nature of the output
86099 depends on the operands selected.

86100 **STDERR**

86101 On completion, *dd* shall write the number of input and output blocks to standard error. In the
86102 POSIX locale the following formats shall be used:

86103 `"%u+%u records in\n", <number of whole input blocks>,`
86104 `    <number of partial input blocks>`

86105 `"%u+%u records out\n", <number of whole output blocks>,`
86106 `    <number of partial output blocks>`

86107 A partial input block is one for which *read*() returned less than the input block size. A partial
86108 output block is one that was written with fewer bytes than specified by the output block size.

86109 In addition, when there is at least one truncated block, the number of truncated blocks shall be
86110 written to standard error. In the POSIX locale, the format shall be:

86111 `"%u truncated %s\n", <number of truncated blocks>, "record" (if`
86112 `    <number of truncated blocks> is one) "records" (otherwise)`

86113 Diagnostic messages may also be written to standard error.

OUTPUT FILES

If the **of**= operand is used, the output shall be the same as described in the STDOUT section.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The input file was copied successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If an input error is detected and the **noerror** conversion has not been specified, any partial output block shall be written to the output file, a diagnostic message shall be written, and the copy operation shall be discontinued. If some other error is detected, a diagnostic message shall be written and the copy operation shall be discontinued.

APPLICATION USAGE

The input and output block size can be specified to take advantage of raw physical I/O.

There are many different versions of the EBCDIC codesets. The ASCII and EBCDIC conversions specified for the *dd* utility perform conversions for the version specified by the tables.

EXAMPLES

The following command:

```
dd if=/dev/rmt0h  of=/dev/rmt1h
```

copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

The following command:

```
dd ibs=10  skip=1
```

strips the first 10 bytes from standard input.

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file **x**:

```
dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

RATIONALE

The OPTIONS section is listed as ``None'' because there are no options recognized by historical *dd* utilities. Certainly, many of the operands could have been designed to use the Utility Syntax Guidelines, which would have resulted in the classic hyphenated option letters. In this version of this volume of POSIX.1-2017, *dd* retains its curious JCL-like syntax due to the large number of applications that depend on the historical implementation.

A suggested implementation technique for **conv**=**noerror**,**sync** is to zero (or <space>-fill, if **block**ing or **unblock**ing) the input buffer before each read and to write the contents of the input buffer to the output even after an error. In this manner, any data transferred to the input buffer before the error was detected is preserved. Another point is that a failed read on a regular file or a disk generally does not increment the file offset, and *dd* must then seek past the block on which the error occurred; otherwise, the input error occurs repetitively. When the input is a magnetic tape, however, the tape normally has passed the block containing the error when the error is reported, and thus no seek is necessary.

The default **ibs**= and **obs**= sizes are specified as 512 bytes because there are historical (largely portable) scripts that assume these values. If they were left unspecified, unusual results could

86157 occur if an implementation chose an odd block size.

86158 Historical implementations of *dd* used *creat*() when processing **of**=*file*. This makes the **seek**=
86159 operand unusable except on special files. The **conv**=**notrunc** feature was added because more
86160 recent BSD-based implementations use *open*() (without O_TRUNC) instead of *creat*(), but they
86161 fail to delete output file contents after the data copied.

86162 The *w* multiplier (historically meaning *word*), is used in System V to mean 2 and in 4.2 BSD to
86163 mean 4. Since *word* is inherently non-portable, its use is not supported by this volume of
86164 POSIX.1-2017.

86165 Standard EBCDIC does not have the characters '[' and ']'. The values used in the table are
86166 taken from a common print train that does contain them. Other than those characters, the print
86167 train values are not filled in, but appear to provide some of the motivation for the historical
86168 choice of translations reflected here.

86169 The Standard EBCDIC table provides a 1:1 translation for all 256 bytes.

86170 The IBM EBCDIC table does not provide such a translation. The marked cells in the tables differ
86171 in such a way that:

86172 1. EBCDIC 0112 ('¢') and 0152 (broken pipe) do not appear in the table.

86173 2. EBCDIC 0137 (' ') translates to/from ASCII 0236 ('^'). In the standard table, EBCDIC
86174 0232 (no graphic) is used.

86175 3. EBCDIC 0241 ('~') translates to/from ASCII 0176 ('~'). In the standard table, EBCDIC
86176 0137 (' ') is used.

86177 4. 0255 ('[') and 0275 (']') appear twice, once in the same place as for the standard table
86178 and once in place of 0112 ('¢') and 0241 ('~').

86179 In net result:

86180 EBCDIC 0275 (']') displaced EBCDIC 0241 ('~') in cell 0345.

86181 That displaced EBCDIC 0137 (' ') in cell 0176.

86182 That displaced EBCDIC 0232 (no graphic) in cell 0136.

86183 That replaced EBCDIC 0152 (broken pipe) in cell 0313.

86184 EBCDIC 0255 ('[') replaced EBCDIC 0112 ('¢').

86185 This translation, however, reflects historical practice that (ASCII) '~' and ' ' were often
86186 mapped to each other, as were '[' and '¢'; and ']' and (EBCDIC) '~'.

86187 The **cbs** operand is required if any of the **ascii**, **ebcdic**, or **ibm** operands are specified. For the
86188 **ascii** operand, the input is handled as described for the **unblock** operand except that characters
86189 are converted to ASCII before the trailing <space> characters are deleted. For the **ebcdic** and
86190 **ibm** operands, the input is handled as described for the **block** operand except that the characters
86191 are converted to EBCDIC or IBM EBCDIC after the trailing <space> characters are added.

86192 The **block** and **unblock** keywords are from historical BSD practice.

86193 The consistent use of the word **record** in standard error messages matches most historical
86194 practice. An earlier version of System V used **block**, but this has been updated in more recent
86195 releases.

86196 Early proposals only allowed two numbers separated by **x** to be used in a product when
86197 specifying **bs**=, **cbs**=, **ibs**=, and **obs**= sizes. This was changed to reflect the historical practice of

allowing multiple numbers in the product as provided by Version 7 and all releases of System V and BSD.

A change to the **swab** conversion is required to match historical practice and is the result of IEEE PASC Interpretations 1003.2 #03 and #04, submitted for the ISO POSIX-2: 1993 standard.

A change to the handling of SIGINT is required to match historical practice and is the result of IEEE PASC Interpretation 1003.2 #06 submitted for the ISO POSIX-2: 1993 standard.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The second paragraph of the **cbs**= description is reworded and marked EX.

The FUTURE DIRECTIONS section is added.

Issue 6

Changes are made to **swab** conversion and SIGINT handling to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE PASC Interpretation 1003.2 #209 is applied, clarifying the interaction between *dd* **of**=*file* and **conv**=**notrunc**.

Issue 7

Austin Group Interpretation 1003.1-2001 #102 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0081 [907] is applied.

NAME

delta ‡’make a delta (change) to an SCCS file(**DEVELOPMENT**)

SYNOPSIS

XSI
```
delta [-nps] [-g list] [-m mrlist] [-r SID] [-y[comment]] file...
```

DESCRIPTION

The *delta* utility shall be used to permanently introduce into the named SCCS files changes that were made to the files retrieved by *get* (called the *g-files*, or generated files).

OPTIONS

The *delta* utility shall conform to XBD Section 12.2 (on page 216), except that the **-y** option has an optional option-argument. This optional option-argument shall not be presented as a separate argument.

The following options shall be supported:

-r *SID* Uniquely identify which delta is to be made to the SCCS file. The use of this option shall be necessary only if two or more outstanding *get* commands for editing (*get* **-e**) on the same SCCS file were done by the same person (login name). The SID value specified with the **-r** option can be either the SID specified on the *get* command line or the SID to be made as reported by the *get* utility; see *get* (on page 2823).

-s Suppress the report to standard output of the activity associated with each *file*. See the STDOUT section.

-n Specify retention of the edited *g-file* (normally removed at completion of delta processing).

-g *list* Specify a *list* (see *get* for the definition of *list*) of deltas that shall be ignored when the file is accessed at the change level (SID) created by this delta.

-m *mrlist* Specify a modification request (MR) number that the application shall supply as the reason for creating the new delta. This shall be used if the SCCS file has the **v** flag set; see *admin*.

If **-m** is not used and `'-'` is not specified as a file argument, and the standard input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued.

MRs in a list shall be separated by <blank> characters or escaped <newline> characters. An unescaped <newline> shall terminate the MR list. The escape character is <backslash>.

If the **v** flag has a value, it shall be taken to be the name of a program which validates the correctness of the MR numbers. If a non-zero exit status is returned from the MR number validation program, the *delta* utility shall terminate. (It is assumed that the MR numbers were not all valid.)

-y[*comment*] Describe the reason for making the delta. The *comment* shall be an arbitrary group of lines that would meet the definition of a text file. Implementations shall support *comment*s from zero to 512 bytes and may support longer values. A null string (specified as either **-y**, **-y**`""`, or in response to a prompt for a comment) shall be considered a valid *comment*.

If **-y** is not specified and `'-'` is not specified as a file argument, and the standard

input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued. An unescaped <newline> shall terminate the comment text. The escape character is <backslash>.

The **−y** option shall be required if the *file* operand is specified as `'−'`.

−p Write (to standard output) the SCCS file differences before and after the delta is applied in *diff* format; see *diff*.

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *delta* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only in the following cases:

To read an *mrlist* or a *comment* (see the **−m** and **−y** options).

A *file* operand shall be specified as `'−'`. In this case, the **−y** option must be used to specify the comment, and if the SCCS file has the **v** flag set, the **−m** option must also be used to specify the MR list.

INPUT FILES

Input files shall be text files whose data is to be included in the SCCS files. If the first character of any line of an input file is <SOH> in the POSIX locale, the results are unspecified. If this file contains more than 99 999 lines, the number of lines recorded in the header for this file shall be 99 999 for this delta.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *delta*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

86310 *TZ* Determine the timezone in which the time and date are written in the SCCS file. If
86311 the *TZ* variable is unset or NULL, an unspecified system default timezone is used.

86312 **ASYNCHRONOUS EVENTS**

86313 If SIGINT is caught, temporary files shall be cleaned up and *delta* shall exit with a non-zero exit
86314 code. The standard action shall be taken for all other signals; see Section 1.4 (on page 2336).

86315 **STDOUT**

86316 The standard output shall be used only for the following messages in the POSIX locale:

86317 Prompts (see the **–m** and **–y** options) in the following formats:

86318 `"MRs? "`

86319 `"comments? "`

86320 The MR prompt, if written, shall always precede the comments prompt.

86321 A report of each file's activities (unless the **–s** option is specified) in the following format:

86322 `"%s\n%d inserted\n%d deleted\n%d unchanged\n", <New SID>,`
86323 `<number of lines inserted>, <number of lines deleted>,`
86324 `<number of lines unchanged>`

86325 **STDERR**

86326 The standard error shall be used only for diagnostic messages.

86327 **OUTPUT FILES**

86328 Any SCCS files updated shall be files of an unspecified format.

86329 **EXTENDED DESCRIPTION**

86330 **System Date and Time**

86331 When a delta is added to an SCCS file, the system date and time shall be recorded for the new
86332 delta. If a *get* is performed using an SCCS file with a date recorded apparently in the future, the
86333 behavior is unspecified.

86334 **EXIT STATUS**

86335 The following exit values shall be returned:

86336 0 Successful completion.

86337 >0 An error occurred.

86338 **CONSEQUENCES OF ERRORS**

86339 Default.

86340 **APPLICATION USAGE**

86341 Problems can arise if the system date and time have been modified (for example, put forward
86342 and then back again, or unsynchronized clocks across a network) and can also arise when
86343 different values of the *TZ* environment variable are used.

86344 Problems of a similar nature can also arise for the operation of the *get* utility, which records the
86345 date and time in the file body.

86346 **EXAMPLES**

86347 None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The output format description in the STDOUT section is corrected.

Issue 6

The APPLICATION USAGE section is added.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The Open Group Base Resolution bwg2001-007 is applied as follows:

The use of `'-'` as a file argument is clarified.

The use of STDIN is added.

The ASYNCHRONOUS EVENTS section is updated to remove the implicit requirement that implementations re-signal themselves when catching a normally fatal signal.

New text is added to the INPUT FILES section warning that the maximum lines recorded in the file is 99 999.

New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections regarding how the system date and time may be taken into account, and the *TZ* environment variable is added to the ENVIRONMENT VARIABLES section as per The Open Group Base Resolution bwg2001-007.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

df — report free disk space

SYNOPSIS

XSI `df [-k] [-P|-t] [file...]`

DESCRIPTION

XSI The *df* utility shall write the amount of available space and file slots for file systems on which the invoking user has appropriate read access. File systems shall be specified by the *file* operands; when none are specified, information shall be written for all file systems. The format of the default output from *df* is unspecified, but all space figures are reported in 512-byte units, unless the **−k** option is specified. This output shall contain at least the file system names, amount XSI of available space on each of these file systems, and, if no options other than **−t** are specified, the number of free file slots, or *inode*s, available; when **−t** is specified, the output shall contain the total allocated space as well.

OPTIONS

The *df* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−k Use 1 024-byte units, instead of the default 512-byte units, when writing space figures.

−P Produce output in the format described in the STDOUT section.

XSI **−t** Include total allocated-space figures in the output.

OPERANDS

The following operand shall be supported:

file A pathname of a file within the hierarchy of the desired file system. If a file other XSI than a FIFO, a regular file, a directory, or a special file representing the device containing the file system (for example, **/dev/dsk/0s1**) is specified, the results are unspecified. If the *file* operand names a file other than a special file containing a file system, *df* shall write the amount of free space in the file system containing the XSI specified *file* operand. Otherwise, *df* shall write the amount of free space in that file system.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *df*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
When both the **−k** and **−P** options are specified, the following header line shall be written (in the POSIX locale):

```
"Filesystem 1024-blocks Used Available Capacity Mounted on\n"
```

When the **−P** option is specified without the **−k** option, the following header line shall be written (in the POSIX locale):

```
"Filesystem 512-blocks Used Available Capacity Mounted on\n"
```

The implementation may adjust the spacing of the header line and the individual data lines so that the information is presented in orderly columns.

The remaining output with **−P** shall consist of one line of information for each specified file system. These lines shall be formatted as follows:

```
"%s %d %d %d %d%% %s\n", <file system name>, <total space>,
    <space used>, <space free>, <percentage used>,
    <file system root>
```

In the following list, all quantities expressed in 512-byte units (1 024-byte when **−k** is specified) shall be rounded up to the next higher unit. The fields are:

<file system name>
The name of the file system, in an implementation-defined format.

<total space> The total size of the file system in 512-byte units. The exact meaning of this figure is implementation-defined, but should include *<space used>*, *<space free>*, plus any space reserved by the system not normally available to a user.

<space used> The total amount of space allocated to existing files in the file system, in 512-byte units.

<space free> The total amount of space available within the file system for the creation of new files by unprivileged users, in 512-byte units. When this figure is less than or equal to zero, it shall not be possible to create any new files on the file system without first deleting others, unless the process has appropriate privileges. The figure written may be less than zero.

<percentage used>
The percentage of the normally available space that is currently allocated to all files on the file system. This shall be calculated using the fraction:

```
<space used>/( <space used>+ <space free>)
```

expressed as a percentage. This percentage may be greater than 100 if *<space free>* is less than zero. The percentage value shall be expressed as a positive integer, with any fractional result causing it to be rounded to the next highest integer.

86460 *<file system root>*
86461 The directory below which the file system hierarchy appears.

86462 XSI The output format is unspecified when **−t** is used.

86463 **STDERR**
86464 The standard error shall be used only for diagnostic messages.

86465 **OUTPUT FILES**
86466 None.

86467 **EXTENDED DESCRIPTION**
86468 None.

86469 **EXIT STATUS**
86470 The following exit values shall be returned:

86471 0 Successful completion.

86472 >0 An error occurred.

86473 **CONSEQUENCES OF ERRORS**
86474 Default.

86475 **APPLICATION USAGE**
86476 On most systems, the ``name of the file system, in an implementation-defined format'' is the
86477 special file on which the file system is mounted.

86478 On large file systems, the calculation specified for percentage used can create huge rounding
86479 errors.

86480 **EXAMPLES**

86481 1. The following example writes portable information about the **/usr** file system:

86482 ```
df −P /usr
```

86483 2. Assuming that **/usr/src** is part of the **/usr** file system, the following produces the same
86484 output as the previous example:

86485 ```
df −P /usr/src
```

86486 **RATIONALE**
86487 The behavior of *df* with the **−P** option is the default action of the 4.2 BSD *df* utility. The uppercase
86488 **−P** was selected to avoid collision with a known industry extension using **−p**.

86489 Historical *df* implementations vary considerably in their default output. It was therefore
86490 necessary to describe the default output in a loose manner to accommodate all known historical
86491 implementations and to add a portable option (**−P**) to provide information in a portable format.

86492 The use of 512-byte units is historical practice and maintains compatibility with *ls* and other
86493 utilities in this volume of POSIX.1-2017. This does not mandate that the file system itself be
86494 based on 512-byte blocks. The **−k** option was added as a compromise measure. It was agreed by
86495 the standard developers that 512 bytes was the best default unit because of its complete
86496 historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and
86497 that a **−k** option to switch to 1 024-byte units was a good compromise. Users who prefer the
86498 more logical 1 024-byte quantity can easily alias *df* to *df* **−k** without breaking many historical
86499 scripts relying on the 512-byte units.

86500 It was suggested that *df* and the various related utilities be modified to access a *BLOCKSIZE*
86501 environment variable to achieve consistency and user acceptance. Since this is not historical

86502 practice on any system, it is left as a possible area for system extensions and will be re-evaluated
86503 in a future version if it is widely implemented.

86504 **FUTURE DIRECTIONS**

86505 None.

86506 **SEE ALSO**

86507 *find*

86508 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

86509 **CHANGE HISTORY**

86510 First released in Issue 2.

86511 **Issue 6**

86512 This utility is marked as part of the User Portability Utilities option.

86513 **Issue 7**

86514 Austin Group Interpretation 1003.1-2001 #099 is applied.

86515 The *df* utility is removed from the User Portability Utilities option. User Portability Utilities is
86516 now an option for interactive utilities.

86517 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

86518 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0082 [156] is applied.

NAME

diff — compare two files

SYNOPSIS

```
diff [-c|-e|-f|-u|-C n|-U n] [-br] file1 file2
```

DESCRIPTION

The *diff* utility shall compare the contents of *file1* and *file2* and write to standard output a list of changes necessary to convert *file1* into *file2*. This list should be minimal. No output shall be produced if the files are identical.

OPTIONS

The *diff* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−b Cause any amount of white space at the end of a line to be treated as a single <newline> (that is, the white-space characters preceding the <newline> are ignored) and other strings of white-space characters, not including <newline> characters, to compare equal.

−c Produce output in a form that provides three lines of copied context.

−C *n* Produce output in a form that provides *n* lines of copied context (where *n* shall be interpreted as a positive decimal integer).

−e Produce output in a form suitable as input for the *ed* utility, which can then be used to convert *file1* into *file2*.

−f Produce output in an alternative form, similar in format to **−e**, but not intended to be suitable as input for the *ed* utility, and in the opposite order.

−r Apply *diff* recursively to files and directories of the same name when *file1* and *file2* are both directories.

The *diff* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *diff* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

−u Produce output in a form that provides three lines of unified context.

−U *n* Produce output in a form that provides *n* lines of unified context (where *n* shall be interpreted as a non-negative decimal integer).

OPERANDS

The following operands shall be supported:

file1, *file2* A pathname of a file to be compared. If either the *file1* or *file2* operand is `'-'`, the standard input shall be used in its place.

If both *file1* and *file2* are directories, *diff* shall not compare block special files, character special files, or FIFO special files to any files and shall not compare regular files to directories. Further details are as specified in Diff Directory Comparison Format (on page 2659). The behavior of *diff* on other file types is implementation-defined when found in directories.

If only one of *file1* and *file2* is a directory, *diff* shall be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.

86561 **STDIN**

86562 The standard input shall be used only if one of the *file1* or *file2* operands references standard
86563 input. See the INPUT FILES section.

86564 **INPUT FILES**

86565 The input files may be of any type.

86566 **ENVIRONMENT VARIABLES**

86567 The following environment variables shall affect the execution of *diff*:

86568 *LANG* Provide a default value for the internationalization variables that are unset or null.
86569 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
86570 variables used to determine the values of locale categories.)

86571 *LC_ALL* If set to a non-empty string value, override the values of all the other
86572 internationalization variables.

86573 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
86574 characters (for example, single-byte as opposed to multi-byte characters in
86575 arguments and input files).

86576 *LC_MESSAGES*

86577 Determine the locale that should be used to affect the format and contents of
86578 diagnostic messages written to standard error and informative messages written to
86579 standard output.

86580 *LC_TIME* Determine the locale for affecting the format of file timestamps written with the **−C**
86581 and **−c** options.

86582 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

86583 *TZ* Determine the timezone used for calculating file timestamps written with a context
86584 format. If *TZ* is unset or null, an unspecified default timezone shall be used.

86585 **ASYNCHRONOUS EVENTS**

86586 Default.

86587 **STDOUT**

86588 **Diff Directory Comparison Format**

86589 If both *file1* and *file2* are directories, the following output formats shall be used.

86590 In the POSIX locale, each file that is present in only one directory shall be reported using the
86591 following format:

86592 `"Only in %s: %s\n", <directory pathname>, <filename>`

86593 In the POSIX locale, subdirectories that are common to the two directories may be reported with
86594 the following format:

86595 `"Common subdirectories: %s and %s\n", <directory1 pathname>,`
86596 `<directory2 pathname>`

86597 For each file common to the two directories, if the two files are not to be compared: if the two
86598 files have the same device ID and file serial number, or are both block special files that refer to
86599 the same device, or are both character special files that refer to the same device, in the POSIX
86600 locale the output format is unspecified. Otherwise, in the POSIX locale an unspecified format
86601 shall be used that contains the pathnames of the two files.

86602 For each file common to the two directories, if the files are compared and are identical, no

86603 output shall be written. If the two files differ, the following format is written:

86604 `"diff %s %s %s\n", <diff_options>, <filename1>, <filename2>`

86605 where <*diff_options*> are the options as specified on the command line.

86606 All directory pathnames listed in this section shall be relative to the original command line
86607 arguments. All other names of files listed in this section shall be filenames (pathname
86608 components).

86609 **Diff Binary Output Format**

86610 In the POSIX locale, if one or both of the files being compared are not text files, it is
86611 implementation-defined whether *diff* uses the binary file output format or the other formats as
86612 specified below. The binary file output format shall contain the pathnames of two files being
86613 compared and the string `"differ"`.

86614 If both files being compared are text files, depending on the options specified, one of the
86615 following formats shall be used to write the differences.

86616 **Diff Default Output Format**

86617 The default (without **−e**, **−f**, **−c**, **−C**, **−u**, or **−U** options) *diff* utility output shall contain lines of
86618 these forms:

86619 `"%da%d\n", <num1>, <num2>`

86620 `"%da%d,%d\n", <num1>, <num2>, <num3>`

86621 `"%dd%d\n", <num1>, <num2>`

86622 `"%d,%dd%d\n", <num1>, <num2>, <num3>`

86623 `"%dc%d\n", <num1>, <num2>`

86624 `"%d,%dc%d\n", <num1>, <num2>, <num3>`

86625 `"%dc%d,%d\n", <num1>, <num2>, <num3>`

86626 `"%d,%dc%d,%d\n", <num1>, <num2>, <num3>, <num4>`

86627 These lines resemble *ed* subcommands to convert *file1* into *file2*. The line numbers before the
86628 action letters shall pertain to *file1*; those after shall pertain to *file2*. Thus, by exchanging *a* for *d*
86629 and reading the line in reverse order, one can also determine how to convert *file2* into *file1*. As in
86630 *ed*, identical pairs (where *num1*= *num2*) are abbreviated as a single number.

86631 Following each of these lines, *diff* shall write to standard output all lines affected in the first file
86632 using the format:

86633 `"<Δ%s", <line>`

86634 and all lines affected in the second file using the format:

86635 `">Δ%s", <line>`

86636 If there are lines affected in both *file1* and *file2* (as with the **c** subcommand), the changes are
86637 separated with a line consisting of three <hyphen-minus> characters:

86638 `"---\n"`

86639 **Diff −e Output Format**

86640 With the −**e** option, a script shall be produced that shall, when provided as input to *ed*, along
86641 with an appended **w** (write) command, convert *file1* into *file2*. Only the **a** (append), **c** (change), **d**
86642 (delete), **i** (insert), and **s** (substitute) commands of *ed* shall be used in this script. Text lines,
86643 except those consisting of the single character <period> (`'.'`), shall be output as they appear in
86644 the file.

86645 **Diff −f Output Format**

86646 With the −**f** option, an alternative format of script shall be produced. It is similar to that
86647 produced by −**e**, with the following differences:

86648 1. It is expressed in reverse sequence; the output of −**e** orders changes from the end of the
86649 file to the beginning; the −**f** from beginning to end.

86650 2. The command form <*lines*> <*command-letter*> used by −**e** is reversed. For example,
86651 10*c* with −**e** would be *c*10 with −**f**.

86652 3. The form used for ranges of line numbers is <space>-separated, rather than
86653 <comma>-separated.

86654 **Diff −c or −C Output Format**

86655 With the −**c** or −**C** option, the output format shall consist of affected lines along with
86656 surrounding lines of context. The affected lines shall show which ones need to be deleted or
86657 changed in *file1*, and those added from *file2*. With the −**c** option, three lines of context, if
86658 available, shall be written before and after the affected lines. With the −**C** option, the user can
86659 specify how many lines of context are written. The exact format follows.

86660 The name and last modification time of each file shall be output in the following format:

86661 `"*** %s %s\n", file1, <file1 timestamp>`
86662 `"--- %s %s\n", file2, <file2 timestamp>`

86663 Each <*file*> field shall be the pathname of the corresponding file being compared. The pathname
86664 written for standard input is unspecified.

86665 In the POSIX locale, each <*timestamp*> field shall be equivalent to the output from the following
86666 command:

86667 `date "+%a %b %e %T %Y"`

86668 without the trailing <newline>, executed at the time of last modification of the corresponding
86669 file (or the current time, if the file is standard input).

86670 Then, the following output formats shall be applied for every set of changes.

86671 First, a line shall be written in the following format:

86672 `"***************\n"`

86673 Next, the range of lines in *file1* shall be written in the following format if the range contains two
86674 or more lines:

86675 `"*** %d,%d ****\n", <beginning line number>, <ending line number>`

86676 and the following format otherwise:

86677 `"*** %d ****\n", <ending line number>`

86678 The ending line number of an empty range shall be the number of the preceding line, or 0 if the

range is at the start of the file.

Next, the affected lines along with lines of context (unaffected lines) shall be written. Unaffected lines shall be written in the following format:

`"ΔΔ%s", <unaffected_line>`

Deleted lines shall be written as:

`"−Δ%s", <deleted_line>`

Changed lines shall be written as:

`"!Δ%s", <changed_line>`

Next, the range of lines in *file2* shall be written in the following format if the range contains two or more lines:

`"−−− %d,%d −−−−\n", <beginning line number>, <ending line number>`

and the following format otherwise:

`"−−− %d −−−−\n", <ending line number>`

Then, lines of context and changed lines shall be written as described in the previous formats. Lines added from *file2* shall be written in the following format:

`"+Δ%s", <added_line>`

Diff −u or −U Output Format

The **−u** or **−U** options behave like the **−c** or **−C** options, except that the context lines are not repeated; instead, the context, deleted, and added lines are shown together, interleaved. The exact format follows.

The name and last modification time of each file shall be output in the following format:

```
"−−−Δ%s\t%s%sΔ%s\n", file1, <file1 timestamp>, <file1 frac>, <file1 zone>
"+++Δ%s\t%s%sΔ%s\n", file2, <file2 timestamp>, <file2 frac>, <file2 zone>
```

Each <*file*> field shall be the pathname of the corresponding file being compared, or the single character `'−'` if standard input is being compared. However, if the pathname contains a <tab> or a <newline>, or if it does not consist entirely of characters taken from the portable character set, the behavior is implementation-defined.

Each <*timestamp*> field shall be equivalent to the output from the following command:

`date '+%Y−%m−%dΔ%H:%M:%S'`

without the trailing <newline>, executed at the time of last modification of the corresponding file (or the current time, if the file is standard input).

Each <*frac*> field shall be either empty, or a decimal point followed by at least one decimal digit, indicating the fractional-seconds part (if any) of the file timestamp. The number of fractional digits shall be at least the number needed to represent the file's timestamp without loss of information.

Each <*zone*> field shall be of the form `"shhmm"`, where `"shh"` is a signed two-digit decimal number in the range −24 through +25, and `"mm"` is an unsigned two-digit decimal number in the range 00 through 59. It represents the timezone of the timestamp as the number of hours (hh) and minutes (mm) east (+) or west (−) of UTC for the timestamp. If the hours and minutes are both zero, the sign shall be `'+'`. However, if the timezone is not an integral number of minutes

away from UTC, the <*zone*> field is implementation-defined.

Then, the following output formats shall be applied for every set of changes.

First, the range of lines in each file shall be written in the following format:

`"@@Δ-%sΔ+%sΔ@@", <file1 range>, <file2 range>`

Each <*range*> field shall be of the form:

`"%1d", <beginning line number>`

or:

`"%1d,1", <beginning line number>`

if the range contains exactly one line, and:

`"%1d,%1d", <beginning line number>, <number of lines>`

otherwise. If a range is empty, its beginning line number shall be the number of the line just before the range, or 0 if the empty range starts the file.

Next, the affected lines along with lines of context shall be written. Each non-empty unaffected line shall be written in the following format:

`"Δ%s", <unaffected_line>`

where the contents of the unaffected line shall be taken from *file1*. It is implementation-defined whether an empty unaffected line is written as an empty line or a line containing a single <space> character. This line also represents the same line of *file2*, even though *file2*'s line may contain different contents due to the **−b**. Deleted lines shall be written as:

`"-%s", <deleted_line>`

Added lines shall be written as:

`"+%s", <added_line>`

The order of lines written shall be the same as that of the corresponding file. A deleted line shall never be written immediately after an added line.

If **−U** *n* is specified, the output shall contain no more than 2*n* consecutive unaffected lines; and if the output contains an affected line and this line is adjacent to up to *n* consecutive unaffected lines in the corresponding file, the output shall contain these unaffected lines. **−u** shall act like **−U**3.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 No differences were found.

1 Differences were found.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If lines at the end of a file are changed and other lines are added, *diff* output may show this as a delete and add, as a change, or as a change and add; *diff* is not expected to know which happened and users should not care about the difference in output as long as it clearly shows the differences between the files.

EXAMPLES

If **dir1** is a directory containing a directory named **x**, **dir2** is a directory containing a directory named **x**, **dir1/x** and **dir2/x** both contain files named **date.out**, and **dir2/x** contains a file named **y**, the command:

```
diff −r dir1 dir2
```

could produce output similar to:

```
Common subdirectories: dir1/x and dir2/x
Only in dir2/x: y
diff −r dir1/x/date.out dir2/x/date.out
1c1
< Mon Jul  2 13:12:16 PDT 1990
−−−
> Tue Jun 19 21:41:39 PDT 1990
```

RATIONALE

The **−h** option was omitted because it was insufficiently specified and does not add to applications portability.

Historical implementations employ algorithms that do not always produce a minimum list of differences; the current language about making every effort is the best this volume of POSIX.1-2017 can do, as there is no metric that could be employed to judge the quality of implementations against any and all file contents. The statement ``This list should be minimal'' clearly implies that implementations are not expected to provide the following output when comparing two 100-line files that differ in only one character on a single line:

```
1,100c1,100
all 100 lines from file1 preceded with "< "
−−−
all 100 lines from file2 preceded with "> "
```

The ``Only in'' messages required when the **−r** option is specified are not used by most historical implementations if the **−e** option is also specified. It is required here because it provides useful information that must be provided to update a target directory hierarchy to match a source hierarchy. The ``Common subdirectories'' messages are written by System V and 4.3 BSD when the **−r** option is specified. They are allowed here but are not required because they are reporting on something that is the same, not reporting a difference, and are not needed to update a target hierarchy.

The **−c** option, which writes output in a format using lines of context, has been included. The format is useful for a variety of reasons, among them being much improved readability and the ability to understand difference changes when the target file has line numbers that differ from another similar, but slightly different, copy. The *patch* utility is most valuable when working with difference listings using a context format. The BSD version of **−c** takes an optional

argument specifying the amount of context. Rather than overloading **−c** and breaking the Utility Syntax Guidelines for *diff*, the standard developers decided to add a separate option for specifying a context diff with a specified amount of context (**−C**). Also, the format for context *diff*s was extended slightly in 4.3 BSD to allow multiple changes that are within context lines from each other to be merged together. The output format contains an additional four <asterisk> characters after the range of affected lines in the first filename. This was to provide a flag for old programs (like old versions of *patch*) that only understand the old context format. The version of context described here does not require that multiple changes within context lines be merged, but it does not prohibit it either. The extension is upwards-compatible, so any vendors that wish to retain the old version of *diff* can do so by adding the extra four <asterisk> characters (that is, utilities that currently use *diff* and understand the new merged format will also understand the old unmerged format, but not *vice versa*).

The **−u** and **−U** options of GNU *diff* have been included. Their output format, designed by Wayne Davison, takes up less space than **−c** and **−C** format, and in many cases is easier to read. The format's timestamps do not vary by locale, so *LC_TIME* does not affect it. The format's line numbers are rendered with the `%1d` format, not `%d`, because the file format notation rules would allow extra <blank> characters to appear around the numbers.

The substitute command was added as an additional format for the **−e** option. This was added to provide implementations with a way to fix the classic ``dot alone on a line'' bug present in many versions of *diff*. Since many implementations have fixed this bug, the standard developers decided not to standardize broken behavior, but rather to provide the necessary tool for fixing the bug. One way to fix this bug is to output two periods whenever a lone period is needed, then terminate the append command with a period, and then use the substitute command to convert the two periods into one period.

The BSD-derived **−r** option was added to provide a mechanism for using *diff* to compare two file system trees. This behavior is useful, is standard practice on all BSD-derived systems, and is not easily reproducible with the *find* utility.

The requirement that *diff* not compare files in some circumstances, even though they have the same name, is based on the actual output of historical implementations. The specified behavior precludes the problems arising from running into FIFOs and other files that would cause *diff* to hang waiting for input with no indication to the user that *diff* was hung. An earlier version of this standard specified the output format more precisely, but in practice this requirement was widely ignored and the benefit of standardization seemed small, so it is now unspecified. In most common usage, *diff* **−r** should indicate differences in the file hierarchies, not the difference of contents of devices pointed to by the hierarchies.

Many early implementations of *diff* require seekable files. Since the System Interfaces volume of POSIX.1-2017 supports named pipes, the standard developers decided that such a restriction was unreasonable. Note also that the allowed filename – almost always refers to a pipe.

No directory search order is specified for *diff*. The historical ordering is, in fact, not optimal, in that it prints out all of the differences at the current level, including the statements about all common subdirectories before recursing into those subdirectories.

The message:

`"diff %s %s %s\n", <diff_options>, <filename1>, <filename2>`

does not vary by locale because it is the representation of a command, not an English sentence.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

The **−f** option is added.

The output format for **−c** or **−C** format is changed to align with changes to the IEEE P1003.2b draft standard resulting from IEEE PASC Interpretation 1003.2 #71.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/20 is applied, changing the STDOUT section. This changes the specification of *diff* **−c** so that it agrees with existing practice when contexts contain zero lines or one line.

Issue 7

Austin Group Interpretations 1003.1-2001 #115 and #114 are applied.

Austin Group Interpretation 1003.1-2001 #192 is applied, clarifying the behavior if both files are non-text files.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-103 and SD5-XCU-ERN-120 are applied, adding the **−u** option.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0082 [584], XCU/TC2-2008/0083 [950], XCU/TC2-2008/0084 [969], and XCU/TC2-2008/0085 [929] are applied.

NAME

dirname — return the directory portion of a pathname

SYNOPSIS

```
dirname string
```

DESCRIPTION

The *string* operand shall be treated as a pathname, as defined in XBD Section 3.271 (on page 76). The string *string* shall be converted to the name of the directory containing the filename corresponding to the last pathname component in *string*, performing actions equivalent to the following steps in order:

1. If *string* is //, skip steps 2 to 5.
2. If *string* consists entirely of <slash> characters, *string* shall be set to a single <slash> character. In this case, skip steps 3 to 8.
3. If there are any trailing <slash> characters in *string*, they shall be removed.
4. If there are no <slash> characters remaining in *string*, *string* shall be set to a single <period> character. In this case, skip steps 5 to 8.
5. If there are any trailing non-<slash> characters in *string*, they shall be removed.
6. If the remaining *string* is //, it is implementation-defined whether steps 7 and 8 are skipped or processed.
7. If there are any trailing <slash> characters in *string*, they shall be removed.
8. If the remaining *string* is empty, *string* shall be set to a single <slash> character.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

string A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *dirname*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *dirname* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The definition of *pathname* specifies implementation-defined behavior for pathnames starting with two <slash> characters. Therefore, applications shall not arbitrarily add <slash> characters to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES

The EXAMPLES section of the *basename*( ) function (see XSH *basename( )*) includes a table showing examples of the results of processing several sample pathnames by the *basename*( ) and *dirname*( ) functions and by the *basename* and *dirname* utilities.

See also the examples for the *basename* utility.

RATIONALE

The behaviors of *basename* and *dirname* in this volume of POSIX.1-2017 have been coordinated so that when *string* is a valid pathname:

```
$(basename -- "string")
```

would be a valid filename for the file in the directory:

```
$(dirname -- "string")
```

This would not work for the versions of these utilities in early proposals due to the way processing of trailing <slash> characters was specified. Consideration was given to leaving processing unspecified if there were trailing <slash> characters, but this cannot be done; XBD Section 3.271 (on page 76) allows trailing <slash> characters. The *basename* and *dirname* utilities have to specify consistent handling for all valid pathnames.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0083 [192,430], XCU/TC1-2008/0084 [192], and XCU/TC1-2008/0085 [192] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0086 [612], XCU/TC2-2008/0087 [620], and XCU/TC2-2008/0088 [612] are applied.

NAME

du ‡'estimate file space usage

SYNOPSIS

```
du [-a|-s] [-kx] [-H|-L] [file...]
```

DESCRIPTION

By default, the *du* utility shall write to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. By default, when a symbolic link is encountered on the command line or in the file hierarchy, *du* shall count the size of the symbolic link (rather than the file referenced by the link), and shall not follow the link to another portion of the file hierarchy. The size of the file space allocated to a file of type directory shall be defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself.

When *du* cannot *stat*( ) files or *stat*( ) or read directories, it shall report an error condition and the final exit status is affected. A file that occurs multiple times under one file operand and that has a link count greater than 1 shall be counted and written for only one entry. It is implementation-defined whether a file that has a link count no greater than 1 is counted and written just once, or is counted and written for each occurrence. It is implementation-defined whether a file that occurs under one file operand is counted for other file operands. The directory entry that is selected in the report is unspecified. By default, file sizes shall be written in 512-byte units, rounded up to the next 512-byte unit.

OPTIONS

The *du* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−a In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. The **−a** option shall not affect whether non-directories given as *file* operands are listed.

−H If a symbolic link is specified on the command line, *du* shall count the size of the file or file hierarchy referenced by the link.

−k Write the files sizes in units of 1 024 bytes, rather than the default 512-byte units.

−L If a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *du* shall count the size of the file or file hierarchy referenced by the link.

−s Instead of the default output, report only the total sum for each of the specified files.

−x When evaluating file sizes, evaluate only those files that have the same device as the file specified by the *file* operand.

Specifying more than one of the mutually-exclusive options **−H** and **−L** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operand shall be supported:

file The pathname of a file whose size is to be written. If no *file* is specified, the current directory shall be used.

87011 **STDIN**

87012 Not used.

87013 **INPUT FILES**

87014 None.

87015 **ENVIRONMENT VARIABLES**

87016 The following environment variables shall affect the execution of *du*:

87017 *LANG* Provide a default value for the internationalization variables that are unset or null.
87018 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
87019 variables used to determine the values of locale categories.)

87020 *LC_ALL* If set to a non-empty string value, override the values of all the other
87021 internationalization variables.

87022 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
87023 characters (for example, single-byte as opposed to multi-byte characters in
87024 arguments).

87025 *LC_MESSAGES*
87026 Determine the locale that should be used to affect the format and contents of
87027 diagnostic messages written to standard error.

87028 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

87029 **ASYNCHRONOUS EVENTS**

87030 Default.

87031 **STDOUT**

87032 The output from *du* shall consist of the amount of space allocated to a file and the name of the
87033 file, in the following format:

87034 `"%d %s\n", <size>, <pathname>`

87035 **STDERR**

87036 The standard error shall be used only for diagnostic messages.

87037 **OUTPUT FILES**

87038 None.

87039 **EXTENDED DESCRIPTION**

87040 None.

87041 **EXIT STATUS**

87042 The following exit values shall be returned:

87043 0 Successful completion.

87044 >0 An error occurred.

87045 **CONSEQUENCES OF ERRORS**

87046 Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The use of 512-byte units is historical practice and maintains compatibility with *ls* and other utilities in this volume of POSIX.1-2017. This does not mandate that the file system itself be based on 512-byte blocks. The **−k** option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and that a **−k** option to switch to 1 024-byte units was a good compromise. Users who prefer the 1 024-byte quantity can easily alias *du* to *du* **−k** without breaking the many historical scripts relying on the 512-byte units.

The **−b** option was added to an early proposal to provide a resolution to the situation where System V and BSD systems give figures for file sizes in *blocks*, which is an implementation-defined concept. (In common usage, the block size is 512 bytes for System V and 1 024 bytes for BSD systems.) However, **−b** was later deleted, since the default was eventually decided as 512-byte units.

Historical file systems provided no way to obtain exact figures for the space allocation given to files. There are two known areas of inaccuracies in historical file systems: cases of *indirect blocks* being used by the file system or *sparse* files yielding incorrectly high values. An indirect block is space used by the file system in the storage of the file, but that need not be counted in the space allocated to the file. A *sparse* file is one in which an *lseek*() call has been made to a position beyond the end of the file and data has subsequently been written at that point. A file system need not allocate all the intervening zero-filled blocks to such a file. It is up to the implementation to define exactly how accurate its methods are.

The **−a** and **−s** options were mutually-exclusive in the original version of *du*. The POSIX Shell and Utilities description is implied by the language in the SVID where **−s** is described as causing ``only the grand total'' to be reported. Some systems may produce output for **−sa**, but a Strictly Conforming POSIX Shell and Utilities Application cannot use that combination.

The **−a** and **−s** options were adopted from the SVID except that the System V behavior of not listing non-directories explicitly given as operands, unless the **−a** option is specified, was considered a bug; the BSD-based behavior (report for all operands) is mandated. The default behavior of *du* in the SVID with regard to reporting the failure to read files (it produces no messages) was considered counter-intuitive, and thus it was specified that the POSIX Shell and Utilities default behavior shall be to produce such messages. These messages can be turned off with shell redirection to achieve the System V behavior.

The **−x** option is historical practice on recent BSD systems. It has been adopted by this volume of POSIX.1-2017 because there was no other historical method of limiting the *du* search to a single file hierarchy. This limitation of the search is necessary to make it possible to obtain file space usage information about a file system on which other file systems are mounted, without having to resort to a lengthy *find* and *awk* script.

FUTURE DIRECTIONS

A future version of this standard may require that a file that occurs multiple times shall be counted and written for only one entry, even if the occurrences are under different file operands.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent **−r** option is removed.

The Open Group Corrigendum U025/3 is applied. The *du* utility is reinstated, as it had incorrectly been marked LEGACY in Issue 5.

The **−H** and **−L** options for symbolic links are added as described in the IEEE P1003.2b draft standard.

Issue 7

The *du* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0089 [527] is applied.

87111 **NAME**

87112 echo — write arguments to standard output

87113 **SYNOPSIS**

87114 `echo [`*`string`*`...]`

87115 **DESCRIPTION**

87116 The *echo* utility writes its arguments to standard output, followed by a <newline>. If there are
87117 no arguments, only the <newline> is written.

87118 **OPTIONS**

87119 The *echo* utility shall not recognize the `"--"` argument in the manner specified by Guideline 10
87120 of XBD Section 12.2 (on page 216); `"--"` shall be recognized as a string operand.

87121 Implementations shall not support any options.

87122 **OPERANDS**

87123 The following operands shall be supported:

87124 *string* A string to be written to standard output. If the first operand is **–n**, or if any of the
87125 operands contain a <backslash> character, the results are implementation-defined.

87126 XSI On XSI-conformant systems, if the first operand is **–n**, it shall be treated as a string,
87127 not an option. The following character sequences shall be recognized on XSI-
87128 conformant systems within any of the arguments:

87129 `\a` Write an <alert>.

87130 `\b` Write a <backspace>.

87131 `\c` Suppress the <newline> that otherwise follows the final argument in the
87132 output. All characters following the `'\c'` in the arguments shall be
87133 ignored.

87134 `\f` Write a <form-feed>.

87135 `\n` Write a <newline>.

87136 `\r` Write a <carriage-return>.

87137 `\t` Write a <tab>.

87138 `\v` Write a <vertical-tab>.

87139 `\\` Write a <backslash> character.

87140 `\0`*`num`* Write an 8-bit value that is the zero, one, two, or three-digit octal number
87141 *num*.

87142 **STDIN**

87143 Not used.

87144 **INPUT FILES**

87145 None.

87146 **ENVIRONMENT VARIABLES**

87147 The following environment variables shall affect the execution of *echo*:

87148 *LANG* Provide a default value for the internationalization variables that are unset or null.
87149 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
87150 variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

XSI *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The *echo* utility arguments shall be separated by single <space> characters and a <newline> XSI character shall follow the last argument. Output transformations shall occur based on the escape sequences in the input. See the OPERANDS section.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
It is not possible to use *echo* portably across all POSIX systems unless both **−n** (as the first argument) and escape sequences are omitted.

The *printf* utility can be used portably to emulate any of the traditional behaviors of the *echo* utility as follows (assuming that *IFS* has its standard value or is unset):

The historic System V *echo* and the requirements on XSI implementations in this volume of POSIX.1-2017 are equivalent to:

```
printf "%b\n" "$*"
```

The BSD *echo* is equivalent to:

```
if [ "X$1" = "X−n" ]
then
    shift
    printf "%s" "$*"
else
    printf "%s\n" "$*"
fi
```

New applications are encouraged to use *printf* instead of *echo*.

EXAMPLES

None.

RATIONALE

The *echo* utility has not been made obsolescent because of its extremely widespread use in historical applications. Conforming applications that wish to do prompting without <newline> characters or that could possibly be expecting to echo a **−n**, should use the *printf* utility derived from the Ninth Edition system.

As specified, *echo* writes its arguments in the simplest of ways. The two different historical versions of *echo* vary in fatally incompatible ways.

The BSD *echo* checks the first argument for the string **−n** which causes it to suppress the <newline> that would otherwise follow the final argument in the output.

The System V *echo* does not support any options, but allows escape sequences within its operands, as described for XSI implementations in the OPERANDS section.

The *echo* utility does not support Utility Syntax Guideline 10 because historical applications depend on *echo* to echo *all* of its arguments, except for the **−n** option in the BSD version.

FUTURE DIRECTIONS

None.

printf

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the OPTIONS section, the last sentence is changed to indicate that implementations ``do not'' support any options; in the previous issue this said ``need not''.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- A set of character sequences is defined as *string* operands.
- *LC_CTYPE* is added to the list of environment variables affecting *echo*.
- In the OPTIONS section, implementations shall not support any options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/21 is applied, so that the *echo* utility can accommodate historical BSD behavior.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ed ‡'edit text

SYNOPSIS

```
ed [-p string] [-s] [file]
```

DESCRIPTION

The *ed* utility is a line-oriented text editor that uses two modes: *command mode* and *input mode*. In command mode the input characters shall be interpreted as commands, and in input mode they shall be interpreted as text. See the EXTENDED DESCRIPTION section.

If an operand is `'-'`, the results are unspecified.

OPTIONS

The *ed* utility shall conform to XBD Section 12.2 (on page 216), except for the unspecified usage of `'-'`.

The following options shall be supported:

-p *string* Use *string* as the prompt string when in command mode. By default, there shall be no prompt string.

-s Suppress the writing of byte counts by **e**, **E**, **r**, and **w** commands and of the `'!'` prompt after a !*command*.

OPERANDS

The following operand shall be supported:

file If the *file* argument is given, *ed* shall simulate an **e** command on the file named by the pathname, *file*, before accepting commands from the standard input.

STDIN

The standard input shall be a text file consisting of commands, as described in the EXTENDED DESCRIPTION section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ed*:

HOME Determine the pathname of the user's home directory.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

87271 *LC_MESSAGES*
87272 Determine the locale that should be used to affect the format and contents of
87273 diagnostic messages written to standard error and informative messages written to
87274 standard output.

87275 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

87276 **ASYNCHRONOUS EVENTS**
87277 The *ed* utility shall take the standard action for all signals (see the ASYNCHRONOUS EVENTS
87278 section in Section 1.4, on page 2336) with the following exceptions:

87279 SIGINT The *ed* utility shall interrupt its current activity, write the string `"?\n"` to standard
87280 output, and return to command mode (see the EXTENDED DESCRIPTION
87281 section).

87282 SIGHUP If the buffer is not empty and has changed since the last write, the *ed* utility shall
87283 attempt to write a copy of the buffer in a file. First, the file named **ed.hup** in the
87284 current directory shall be used; if that fails, the file named **ed.hup** in the directory
87285 named by the *HOME* environment variable shall be used. In any case, the *ed* utility
87286 shall exit without writing the file to the currently remembered pathname and
87287 without returning to command mode.

87288 SIGQUIT The *ed* utility shall ignore this event.

87289 **STDOUT**
87290 Various editing commands and the prompting feature (see **−p**) write to standard output, as
87291 described in the EXTENDED DESCRIPTION section.

87292 **STDERR**
87293 The standard error shall be used only for diagnostic messages.

87294 **OUTPUT FILES**
87295 The output files shall be text files whose formats are dependent on the editing commands given.

87296 **EXTENDED DESCRIPTION**
87297 The *ed* utility shall operate on a copy of the file it is editing; changes made to the copy shall have
87298 no effect on the file until a **w** (write) command is given. The copy of the text is called the *buffer*.

87299 Commands to *ed* have a simple and regular structure: zero, one, or two *addresses* followed by a
87300 single-character *command*, possibly followed by parameters to that command. These addresses
87301 specify one or more lines in the buffer. Every command that requires addresses has default
87302 addresses, so that the addresses very often can be omitted. If the **−p** option is specified, the
87303 prompt string shall be written to standard output before each command is read.

87304 In general, only one command can appear on a line. Certain commands allow text to be input.
87305 This text is placed in the appropriate place in the buffer. While *ed* is accepting text, it is said to be
87306 in *input mode*. In this mode, no commands shall be recognized; all input is merely collected.
87307 Input mode is terminated by entering a line consisting of two characters: a <period> (`'.'`)
87308 followed by a <newline>. This line is not considered part of the input text.

87309 **Regular Expressions in ed**

87310 The *ed* utility shall support basic regular expressions, as described in XBD Section 9.3 (on page
87311 183). Since regular expressions in *ed* are always matched against single lines (excluding the
87312 terminating <newline> characters), never against any larger section of text, there is no way for a
87313 regular expression to match a <newline>.

87314 A null RE shall be equivalent to the last RE encountered.

87315 Regular expressions are used in addresses to specify lines, and in some commands (for example,
87316 the **s** substitute command) to specify portions of a line to be substituted.

87317 **Addresses in ed**

87318 Addressing in *ed* relates to the current line. Generally, the current line is the last line affected by a
87319 command. The current line number is the address of the current line. If the edit buffer is not
87320 empty, the initial value for the current line shall be the last line in the edit buffer; otherwise, zero.

87321 Addresses shall be constructed as follows:

87322 1. The <period> character (`'.'`) shall address the current line.

87323 2. The <dollar-sign> character (`'$'`) shall address the last line of the edit buffer.

87324 3. The positive decimal number *n* shall address the *n*th line of the edit buffer.

87325 4. The <apostrophe>-x character pair (`"'x"`) shall address the line marked with the mark
87326 name character *x*, which shall be a lowercase letter from the portable character set. It shall
87327 be an error if the character has not been set to mark a line or if the line that was marked is
87328 not currently present in the edit buffer.

87329 5. A BRE enclosed by <slash> characters (`'/'`) shall address the first line found by
87330 searching forwards from the line following the current line toward the end of the edit
87331 buffer and stopping at the first line for which the line excluding the terminating
87332 <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of
87333 <slash> characters shall address the next line for which the line excluding the terminating
87334 <newline> matches the last BRE encountered. In addition, the second <slash> can be
87335 omitted at the end of a command line. Within the BRE, a <backslash>-<slash> pair (`"\/"`)
87336 shall represent a literal <slash> instead of the BRE delimiter. If necessary, the search shall
87337 wrap around to the beginning of the buffer and continue up to and including the current
87338 line, so that the entire buffer is searched.

87339 6. A BRE enclosed by <question-mark> characters (`'?'`) shall address the first line found by
87340 searching backwards from the line preceding the current line toward the beginning of the
87341 edit buffer and stopping at the first line for which the line excluding the terminating
87342 <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of
87343 <question-mark> characters (`"??"`) shall address the previous line for which the line
87344 excluding the terminating <newline> matches the last BRE encountered. In addition, the
87345 second <question-mark> can be omitted at the end of a command line. Within the BRE, a
87346 <backslash>-<question-mark> pair (`"\?"`) shall represent a literal <question-mark>
87347 instead of the BRE delimiter. If necessary, the search shall wrap around to the end of the
87348 buffer and continue up to and including the current line, so that the entire buffer is
87349 searched.

87350 7. A <plus-sign> (`'+'`) or <hyphen-minus> character (`'-'`) followed by a decimal number
87351 shall address the current line plus or minus the number. A <plus-sign> or <hyphen-
87352 minus> character not followed by a decimal number shall address the current line plus or
87353 minus 1.

Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:

> A <plus-sign> or <hyphen-minus> character followed by a decimal number shall add or subtract, respectively, the indicated number of lines to or from the address. A <plus-sign> or <hyphen-minus> character not followed by a decimal number shall add or subtract 1 to or from the address.
>
> A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer. It shall be an error if a search for a BRE fails to find a matching line.

Commands accept zero, one, or two addresses. If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain, for the specified command.

Addresses shall be separated from each other by a <comma> (`','`) or <semicolon> character (`';'`). In the case of a <semicolon> separator, the current line (`'.'`) shall be set to the first address, and only then will the second address be calculated. This feature can be used to determine the starting line for forwards and backwards searches; see rules 5. and 6.

Addresses can be omitted on either side of the <comma> or <semicolon> separator, in which case the resulting address pairs shall be as follows:

Specified	Resulting
`,`	`1 , $`
`, addr`	`1 , addr`
`addr ,`	`addr , addr`
`;`	`. ; $`
`; addr`	`. ; addr`
`addr ;`	`addr ; addr`

Any <blank> characters included between addresses, address separators, or address offsets shall be ignored.

Commands in ed

In the following list of *ed* commands, the default addresses are shown in parentheses. The number of addresses shown in the default shall be the number expected by the command. The parentheses are not part of the address; they show that the given addresses are the default.

It is generally invalid for more than one command to appear on a line. However, any command (except **e**, **E**, **f**, **q**, **Q**, **r**, **w**, and **!**) can be suffixed by the letter **l**, **n**, or **p**; in which case, except for the **l**, **n**, and **p** commands, the command shall be executed and then the new current line shall be written as described below under the **l**, **n**, and **p** commands. When an **l**, **n**, or **p** suffix is used with an **l**, **n**, or **p** command, the command shall write to standard output as described below, but it is unspecified whether the suffix writes the current line again in the requested format or whether the suffix has no effect. For example, the **pl** command (base **p** command with an **l** suffix) shall either write just the current line or write it twice—once as specified for **p** and once as specified for **l**. Also, the **g**, **G**, **v**, and **V** commands shall take a command as a parameter.

Each address component can be preceded by zero or more <blank> characters. The command

letter can be preceded by zero or more <blank> characters. If a suffix letter (**l**, **n**, or **p**) is given, the application shall ensure that it immediately follows the command.

The **e**, **E**, **f**, **r**, and **w** commands shall take an optional *file* parameter, separated from the command letter by one or more <blank> characters.

If changes have been made in the buffer since the last **w** command that wrote the entire buffer, *ed* shall warn the user if an attempt is made to destroy the editor buffer via the **e** or **q** commands. The *ed* utility shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged. If the **e** or **q** command is repeated with no intervening command, it shall take effect.

If a terminal disconnect (see XBD Chapter 11 (on page 199), Modem Disconnect and Closing a Device Terminal), is detected:

> If accompanied by a SIGHUP signal, the *ed* utility shall operate as described in the ASYNCHRONOUS EVENTS section for a SIGHUP signal.
>
> If not accompanied by a SIGHUP signal, the *ed* utility shall act as if an end-of-file had been detected on standard input.

If an end-of-file is detected on standard input:

> If the *ed* utility is in input mode, *ed* shall terminate input mode and return to command mode. It is unspecified if any partially entered lines (that is, input text without a terminating <newline>) are discarded from the input text.
>
> If the *ed* utility is in command mode, it shall act as if a **q** command had been entered.

If the closing delimiter of an RE or of a replacement string (for example, `'/'`) in a **g**, **G**, **s**, **v**, or **V** command would be the last character before a <newline>, that delimiter can be omitted, in which case the addressed line shall be written. For example, the following pairs of commands are equivalent:

```
s/s1/s2     s/s1/s2/p
g/s1        g/s1/p
?s1         ?s1?
```

If an invalid command is entered, *ed* shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged.

Append Command

Synopsis:

```
(.)a
<text>
.
```

The **a** command shall read the given text and append it after the addressed line; the current line number shall become the address of the last inserted line or, if there were none, the addressed line. Address 0 shall be valid for this command; it shall cause the appended text to be placed at the beginning of the buffer.

87440 **Change Command**

87441 *Synopsis*: `(.,.)c`
87442 `<text>`
87443 `.`

87444 The **c** command shall delete the addressed lines, then accept input text that replaces these lines;
87445 the current line shall be set to the address of the last line input; or, if there were none, at the line
87446 after the last line deleted; if the lines deleted were originally at the end of the buffer, the current
87447 line number shall be set to the address of the new last line; if no lines remain in the buffer, the
87448 current line number shall be set to zero. Address 0 shall be valid for this command; it shall be
87449 interpreted as if address 1 were specified.

87450 **Delete Command**

87451 *Synopsis*: `(.,.)d`

87452 The **d** command shall delete the addressed lines from the buffer. The address of the line after the
87453 last line deleted shall become the current line number; if the lines deleted were originally at the
87454 end of the buffer, the current line number shall be set to the address of the new last line; if no
87455 lines remain in the buffer, the current line number shall be set to zero.

87456 **Edit Command**

87457 *Synopsis*: `e [`*file*`]`

87458 The **e** command shall delete the entire contents of the buffer and then read in the file named by
87459 the pathname *file*. The current line number shall be set to the address of the last line of the
87460 buffer. If no pathname is given, the currently remembered pathname, if any, shall be used (see
87461 the **f** command). The number of bytes read shall be written to standard output, unless the **−s**
87462 option was specified, in the following format:

87463 `"%d\n",` *<number of bytes read>*

87464 The name *file* shall be remembered for possible use as a default pathname in subsequent **e**, **E**, **r**,
87465 and **w** commands. If *file* is replaced by `'!'`, the rest of the line shall be taken to be a shell
87466 command line whose output is to be read. Such a shell command line shall not be remembered
87467 as the current *file*. All marks shall be discarded upon the completion of a successful **e** command.
87468 If the buffer has changed since the last time the entire buffer was written, the user shall be
87469 warned, as described previously.

87470 **Edit Without Checking Command**

87471 *Synopsis*: `E [`*file*`]`

87472 The **E** command shall possess all properties and restrictions of the **e** command except that the
87473 editor shall not check to see whether any changes have been made to the buffer since the last **w**
87474 command.

87475 **Filename Command**

87476 *Synopsis*: `f [`*`file`*`]`

87477 If *file* is given, the **f** command shall change the currently remembered pathname to *file*; whether
87478 the name is changed or not, it shall then write the (possibly new) currently remembered
87479 pathname to the standard output in the following format:

87480 `"%s\n", <`*`pathname`*`>`

87481 The current line number shall be unchanged.

87482 **Global Command**

87483 *Synopsis*: `(1,$)g/`*`RE`*`/`*`command list`*

87484 In the **g** command, the first step shall be to mark every line for which the line excluding the
87485 terminating <newline> matches the given RE. Then, going sequentially from the beginning of
87486 the file to the end of the file, the given *command list* shall be executed for each marked line, with
87487 the current line number set to the address of that line. Any line modified by the *command list*
87488 shall be unmarked. When the **g** command completes, the current line number shall have the
87489 value assigned by the last command in the *command list*. If there were no matching lines, the
87490 current line number shall not be changed. A single command or the first of a list of commands
87491 shall appear on the same line as the global command. All lines of a multi-line list except the last
87492 line shall be ended with a <backslash> preceding the terminating <newline>; the **a**, **i**, and **c**
87493 commands and associated input are permitted. The `'.'` terminating input mode can be omitted
87494 if it would be the last line of the *command list*. An empty *command list* shall be equivalent to the **p**
87495 command. The use of the **g**, **G**, **v**, **V**, and **!** commands in the *command list* produces undefined
87496 results. Any character other than <space> or <newline> can be used instead of a <slash> to
87497 delimit the RE. Within the RE, the RE delimiter itself can be used as a literal character if it is
87498 preceded by a <backslash>.

87499 **Interactive Global Command**

87500 *Synopsis*: `(1,$)G/`*`RE`*`/`

87501 In the **G** command, the first step shall be to mark every line for which the line excluding the
87502 terminating <newline> matches the given RE. Then, for every such line, that line shall be
87503 written, the current line number shall be set to the address of that line, and any one command
87504 (other than one of the **a**, **c**, **i**, **g**, **G**, **v**, and **V** commands) shall be read and executed. A <newline>
87505 shall act as a null command (causing no action to be taken on the current line); an `'&'` shall
87506 cause the re-execution of the most recent non-null command executed within the current
87507 invocation of **G**. Note that the commands input as part of the execution of the **G** command can
87508 address and affect any lines in the buffer. Any line modified by the command shall be
87509 unmarked. The final value of the current line number shall be the value set by the last command
87510 successfully executed. (Note that the last command successfully executed shall be the **G**
87511 command itself if a command fails or the null command is specified.) If there were no matching
87512 lines, the current line number shall not be changed. The **G** command can be terminated by a
87513 SIGINT signal. Any character other than <space> or <newline> can be used instead of a <slash>
87514 to delimit the RE and the replacement. Within the RE, the RE delimiter itself can be used as a
87515 literal character if it is preceded by a <backslash>.

87516 **Help Command**

87517 *Synopsis*: `h`

87518 The **h** command shall write a short message to standard output that explains the reason for the
87519 most recent `'?'` notification. The current line number shall be unchanged.

87520 **Help-Mode Command**

87521 *Synopsis*: `H`

87522 The **H** command shall cause *ed* to enter a mode in which help messages (see the **h** command)
87523 shall be written to standard output for all subsequent `'?'` notifications. The **H** command
87524 alternately shall turn this mode on and off; it is initially off. If the help-mode is being turned on,
87525 the **H** command also explains the previous `'?'` notification, if there was one. The current line
87526 number shall be unchanged.

87527 **Insert Command**

87528 *Synopsis*: `(.)i`
87529 `<`*text*`>`
87530 `.`

87531 The **i** command shall insert the given text before the addressed line; the current line is set to the
87532 last inserted line or, if there was none, to the addressed line. This command differs from the **a**
87533 command only in the placement of the input text. Address 0 shall be valid for this command; it
87534 shall be interpreted as if address 1 were specified.

87535 **Join Command**

87536 *Synopsis*: `(.,.+1)j`

87537 The **j** command shall join contiguous lines by removing the appropriate <newline> characters. If
87538 exactly one address is given, this command shall do nothing. If lines are joined, the current line
87539 number shall be set to the address of the joined line; otherwise, the current line number shall be
87540 unchanged.

87541 **Mark Command**

87542 *Synopsis*: `(.)k`*x*

87543 The **k** command shall mark the addressed line with name *x*, which the application shall ensure
87544 is a lowercase letter from the portable character set. The address `"'x"` shall then refer to this
87545 line; the current line number shall be unchanged.

87546 **List Command**

87547 *Synopsis*: `(.,.)l`

87548 The **l** command shall write to standard output the addressed lines in a visually unambiguous
87549 form. The characters listed in XBD Table 5-1 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`,
87550 `'\t'`, `'\v'`) shall be written as the corresponding escape sequence; the `'\n'` in that table is not
87551 applicable. Non-printable characters not in the table shall be written as one three-digit octal
87552 number (with a preceding <backslash> character) for each byte in the character (most significant
87553 byte first).

87554 Long lines shall be folded, with the point of folding indicated by <newline> preceded by a
87555 <backslash>; the length at which folding occurs is unspecified, but should be appropriate for the

output device. The end of each line shall be marked with a `'$'`, and `'$'` characters within the text shall be written with a preceding <backslash>. An **l** command can be appended to any other command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**. The current line number shall be set to the address of the last line written.

Move Command

Synopsis: `(.,.)m`*address*

The **m** command shall reposition the addressed lines after the line addressed by *address*. Address 0 shall be valid for *address* and cause the addressed lines to be moved to the beginning of the buffer. It shall be an error if address *address* falls within the range of moved lines. The current line number shall be set to the address of the last line moved.

Number Command

Synopsis: `(.,.)n`

The **n** command shall write to standard output the addressed lines, preceding each line by its line number and a <tab>; the current line number shall be set to the address of the last line written. The **n** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

Print Command

Synopsis: `(.,.)p`

The **p** command shall write to standard output the addressed lines; the current line number shall be set to the address of the last line written. The **p** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

Prompt Command

Synopsis: `P`

The **P** command shall cause *ed* to prompt with an <asterisk> (`'*'`) (or *string*, if −**p** is specified) for all subsequent commands. The **P** command alternatively shall turn this mode on and off; it shall be initially on if the −**p** option is specified; otherwise, off. The current line number shall be unchanged.

Quit Command

Synopsis: `q`

The **q** command shall cause *ed* to exit. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

Quit Without Checking Command

Synopsis: `Q`

The **Q** command shall cause *ed* to exit without checking whether changes have been made in the buffer since the last **w** command.

87590 **Read Command**

87591 *Synopsis*: `(`$`)r` **[***file***]**

87592 The **r** command shall read in the file named by the pathname *file* and append it after the
87593 addressed line. If no *file* argument is given, the currently remembered pathname, if any, shall be
87594 used (see the **e** and **f** commands). The currently remembered pathname shall not be changed
87595 unless there is no remembered pathname. Address 0 shall be valid for **r** and shall cause the file
87596 to be read at the beginning of the buffer. If the read is successful, and **–s** was not specified, the
87597 number of bytes read shall be written to standard output in the following format:

87598 `"%d\n", <number of bytes read>`

87599 The current line number shall be set to the address of the last line read in. If *file* is replaced by
87600 `'!'`, the rest of the line shall be taken to be a shell command line whose output is to be read.
87601 Such a shell command line shall not be remembered as the current pathname.

87602 **Substitute Command**

87603 *Synopsis*: `(.,.)s/`*RE*`/`*replacement*`/`*flags*

87604 The **s** command shall search each addressed line for an occurrence of the specified RE and
87605 replace either the first or all (non-overlapped) matched strings with the *replacement*; see the
87606 following description of the **g** suffix. It is an error if the substitution fails on every addressed
87607 line. Any character other than <space> or <newline> can be used instead of a <slash> to delimit
87608 the RE and the replacement. Within the RE, the RE delimiter itself can be used as a literal
87609 character if it is preceded by a <backslash>. The current line shall be set to the address of the
87610 last line on which a substitution occurred.

87611 An <ampersand> (`'&'`) appearing in the *replacement* shall be replaced by the string matching the
87612 RE on the current line. The special meaning of `'&'` in this context can be suppressed by
87613 preceding it by <backslash>. As a more general feature, the characters `'\n'`, where *n* is a digit,
87614 shall be replaced by the text matched by the corresponding back-reference expression. If the
87615 corresponding back-reference expression does not match, then the characters `'\n'` shall be
87616 replaced by the empty string. When the character `'%'` is the only character in the *replacement*, the
87617 *replacement* used in the most recent substitute command shall be used as the *replacement* in the
87618 current substitute command; if there was no previous substitute command, the use of `'%'` in this
87619 manner shall be an error. The `'%'` shall lose its special meaning when it is in a replacement
87620 string of more than one character or is preceded by a <backslash>. For each <backslash>
87621 encountered in scanning *replacement* from beginning to end, the following character shall lose its
87622 special meaning (if any). It is unspecified what special meaning is given to any character other
87623 than <backslash>, `'&'`, `'%'`, or digits.

87624 A line can be split by substituting a <newline> into it. The application shall ensure it escapes the
87625 <newline> in the *replacement* by preceding it by <backslash>. Such substitution cannot be done
87626 as part of a **g** or **v** *command list*. The current line number shall be set to the address of the last
87627 line on which a substitution is performed. If no substitution is performed, the current line
87628 number shall be unchanged. If a line is split, a substitution shall be considered to have been
87629 performed on each of the new lines for the purpose of determining the new current line number.
87630 A substitution shall be considered to have been performed even if the replacement string is
87631 identical to the string that it replaces.

87632 The application shall ensure that the value of *flags* is zero or more of:

87633 *count* Substitute for the *count*th occurrence only of the RE found on each addressed line.

87634 **g** Globally substitute for all non-overlapping instances of the RE rather than just the first
87635 one. If both **g** and *count* are specified, the results are unspecified.

87636 **l** Write to standard output the final line in which a substitution was made. The line shall
87637 be written in the format specified for the **l** command.

87638 **n** Write to standard output the final line in which a substitution was made. The line shall
87639 be written in the format specified for the **n** command.

87640 **p** Write to standard output the final line in which a substitution was made. The line shall
87641 be written in the format specified for the **p** command.

87642 **Copy Command**

87643 *Synopsis*: `(.,.)t`*`address`*

87644 The **t** command shall be equivalent to the **m** command, except that a copy of the addressed lines
87645 shall be placed after address *address* (which can be 0); the current line number shall be set to the
87646 address of the last line added.

87647 **Undo Command**

87648 *Synopsis*: `u`

87649 The **u** command shall nullify the effect of the most recent command that modified anything in
87650 the buffer, namely the most recent **a**, **c**, **d**, **g**, **i**, **j**, **m**, **r**, **s**, **t**, **u**, **v**, **G**, or **V** command. All changes
87651 made to the buffer by a **g**, **G**, **v**, or **V** global command shall be undone as a single change; if no
87652 changes were made by the global command (such as with **g**/RE/**p**), the **u** command shall have
87653 no effect. The current line number shall be set to the value it had immediately before the
87654 command being undone started.

87655 **Global Non-Matched Command**

87656 *Synopsis*: `(1,$)v/`*`RE`*`/`*`command list`*

87657 This command shall be equivalent to the global command **g** except that the lines that are marked
87658 during the first step shall be those for which the line excluding the terminating <newline> does
87659 not match the RE.

87660 **Interactive Global Not-Matched Command**

87661 *Synopsis*: `(1,$)V/`*`RE`*`/`

87662 This command shall be equivalent to the interactive global command **G** except that the lines that
87663 are marked during the first step shall be those for which the line excluding the terminating
87664 <newline> does not match the RE.

87665 **Write Command**

87666 *Synopsis*: `(1,$)w [`*`file`*`]`

87667 The **w** command shall write the addressed lines into the file named by the pathname *file*. The
87668 command shall create the file, if it does not exist, or shall replace the contents of the existing file.
87669 The currently remembered pathname shall not be changed unless there is no remembered
87670 pathname. If no pathname is given, the currently remembered pathname, if any, shall be used
87671 (see the **e** and **f** commands); the current line number shall be unchanged. If the command is
87672 successful, the number of bytes written shall be written to standard output, unless the **−s** option
87673 was specified, in the following format:

87674 `"%d\n", <number of bytes written>`

87675 If *file* begins with `'!'`, the rest of the line shall be taken to be a shell command line whose
87676 standard input shall be the addressed lines. Such a shell command line shall not be remembered
87677 as the current pathname. This usage of the write command with `'!'` shall not be considered as a
87678 ``last **w** command that wrote the entire buffer'', as described previously; thus, this alone shall
87679 not prevent the warning to the user if an attempt is made to destroy the editor buffer via the **e** or
87680 **q** commands.

87681 **Line Number Command**

87682 *Synopsis*: `($)=`

87683 The line number of the addressed line shall be written to standard output in the following
87684 format:

87685 `"%d\n", <line number>`

87686 The current line number shall be unchanged by this command.

87687 **Shell Escape Command**

87688 *Synopsis*: `!command`

87689 The remainder of the line after the `'!'` shall be sent to the command interpreter to be
87690 interpreted as a shell command line. Within the text of that shell command line, the unescaped
87691 character `'%'` shall be replaced with the remembered pathname; if a `'!'` appears as the first
87692 character of the command, it shall be replaced with the text of the previous shell command
87693 executed via `'!'`. Thus, `"!!"` shall repeat the previous !*command*. If any replacements of `'%'` or
87694 `'!'` are performed, the modified line shall be written to the standard output before *command* is
87695 executed. The **!** command shall write:

87696 `"!\n"`

87697 to standard output upon completion, unless the −**s** option is specified. The current line number
87698 shall be unchanged.

87699 **Null Command**

87700 *Synopsis*: `(.+1)`

87701 An address alone on a line shall cause the addressed line to be written. A <newline> alone shall
87702 be equivalent to `"+1p"`. The current line number shall be set to the address of the written line.

87703 **EXIT STATUS**

87704 The following exit values shall be returned:

87705 0 Successful completion without any file or command errors.

87706 >0 An error occurred.

87707 **CONSEQUENCES OF ERRORS**

87708 When an error in the input script is encountered, or when an error is detected that is a
87709 consequence of the data (not) present in the file or due to an external condition such as a read or
87710 write error:

87711 If the standard input is a terminal device file, all input shall be flushed, and a new
87712 command read.

If the standard input is a regular file, *ed* shall terminate with a non-zero exit status.

APPLICATION USAGE

Because of the extremely terse nature of the default error messages, the prudent script writer begins the *ed* input commands with an **H** command, so that if any errors do occur at least some clue as to the cause is made available.

In earlier versions of this standard, an obsolescent − option was described. This is no longer specified. Applications should use the −**s** option. Using − as a *file* operand now produces unspecified results. This allows implementations to continue to support the former required behavior.

EXAMPLES

None.

RATIONALE

The initial description of this utility was adapted from the SVID. It contains some features not found in Version 7 or BSD-derived systems. Some of the differences between the POSIX and BSD *ed* utilities include, but need not be limited to:

The BSD − option does not suppress the `'!'` prompt after a **!** command.

BSD does not support the special meanings of the `'%'` and `'!'` characters within a **!** command.

BSD does not support the *addresses* `';'` and `','`.

BSD allows the command/suffix pairs **pp**, **ll**, and so on, which are unspecified in this volume of POSIX.1-2017.

BSD does not support the `'!'` character part of the **e**, **r**, or **w** commands.

A failed **g** command in BSD sets the line number to the last line searched if there are no matches.

BSD does not default the *command list* to the **p** command.

BSD does not support the **G**, **h**, **H**, **n**, or **V** commands.

On BSD, if there is no inserted text, the insert command changes the current line to the referenced line −1; that is, the line before the specified line.

On BSD, the *join* command with only a single address changes the current line to that address.

BSD does not support the **P** command; moreover, in BSD it is synonymous with the **p** command.

BSD does not support the *undo* of the commands **j**, **m**, **r**, **s**, or **t**.

The Version 7 *ed* command **W**, and the BSD *ed* commands **W**, **wq**, and **z** are not present in this volume of POSIX.1-2017.

The −**s** option was added to allow the functionality of the removed − option in a manner compatible with the Utility Syntax Guidelines.

In early proposals there was a limit, {ED_FILE_MAX}, that described the historical limitations of some *ed* utilities in their handling of large files; some of these have had problems with files larger than 100 000 bytes. It was this limitation that prompted much of the desire to include a *split* command in this volume of POSIX.1-2017. Since this limit was removed, this volume of POSIX.1-2017 requires that implementations document the file size limits imposed by *ed* in the

conformance document. The limit {ED_LINE_MAX} was also removed; therefore, the global limit {LINE_MAX} is used for input and output lines.

The manner in which the **l** command writes non-printable characters was changed to avoid the historical backspace-overstrike method. On video display terminals, the overstrike is ambiguous because most terminals simply replace overstruck characters, making the **l** format not useful for its intended purpose of unambiguously understanding the content of the line. The historical <backslash>-escapes were also ambiguous. (The string `"a\0011"` could represent a line containing those six characters or a line containing the three characters `'a'`, a byte with a binary value of 1, and a 1.) In the format required here, a <backslash> appearing in the line is written as `"\\"` so that the output is truly unambiguous. The method of marking the ends of lines was adopted from the *ex* editor and is required for any line ending in <space> characters; the `'$'` is placed on all lines so that a real `'$'` at the end of a line cannot be misinterpreted.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

The description of how a NUL is written was removed. The NUL character cannot be in text files, and this volume of POSIX.1-2017 should not dictate behavior in the case of undefined, erroneous input.

Unlike some of the other editing utilities, the filenames accepted by the **E**, **e**, **R**, and **r** commands are not patterns.

Early proposals stated that the −**p** option worked only when standard input was associated with a terminal device. This has been changed to conform to historical implementations, thereby allowing applications to interpose themselves between a user and the *ed* utility.

The form of the substitute command that uses the **n** suffix was limited in some historical documentation (where this was described incorrectly as ``backreferencing''). This limit has been omitted because there is no reason why an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/x/X/2047** should be able to substitute the 2 047th occurrence of `'x'` on a line.

The use of printing commands with printing suffixes (such as **pn**, **lp**, and so on) was made unspecified because BSD-based systems allow this, whereas System V does not.

Some BSD-based systems exit immediately upon receipt of end-of-file if all of the lines in the file have been deleted. Since this volume of POSIX.1-2017 refers to the **q** command in this instance, such behavior is not allowed.

Some historical implementations returned exit status zero even if command errors had occurred; this is not allowed by this volume of POSIX.1-2017.

Some historical implementations contained a bug that allowed a single <period> to be entered in input mode as <backslash> <period> <newline>. This is not allowed by *ed* because there is no description of escaping any of the characters in input mode; <backslash> characters are entered into the buffer exactly as typed. The typical method of entering a single <period> has been to precede it with another character and then use the substitute command to delete that character.

It is difficult under some modes of some versions of historical operating system terminal drivers to distinguish between an end-of-file condition and terminal disconnect. POSIX.1-2017 does not require implementations to distinguish between the two situations, which permits historical implementations of the *ed* utility on historical platforms to conform. Implementations are encouraged to distinguish between the two, if possible, and take appropriate action on terminal disconnect.

Historically, *ed* accepted a zero address for the **a** and **r** commands in order to insert text at the

start of the edit buffer. When the buffer was empty the command **.=** returned zero. POSIX.1-2017 requires conformance to historical practice.

For consistency with the **a** and **r** commands and better user functionality, the **i** and **c** commands must also accept an address of 0, in which case 0*i* is treated as 1*i* and likewise for the **c** command.

All of the following are valid addresses:

`+++`	Three lines after the current line.
`/pattern/-`	One line before the next occurrence of pattern.
`-2`	Two lines before the current line.
`3 ---- 2`	Line one (note the intermediate negative address).
`1 2 3`	Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the <semicolon> delimiter, permits users to create commands based on ordered patterns in the file. For example, the command `"3;/foo/;+2p"` will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address `"3;"` must still be evaluated before being discarded, because the search origin for the `"/foo/"` command depends on this.

Historically, *ed* disallowed address chains, as discussed above, consisting solely of <comma> or <semicolon> separators; for example, `",,,"` or `";;;"` were considered an error. For consistency of address specification, this restriction is removed. The following table lists some of the address forms now possible:

Address	Addr1	Addr2	Status	Comment
`7,`	7	7	Historical	
`7,5,`	5	5	Historical	
`7,5,9`	5	9	Historical	
`7,9`	7	9	Historical	
`7,+`	7	8	Historical	
`,`	1	`$`	Historical	
`,7`	1	7	Extension	
`,,`	`$`	`$`	Extension	
`,;`	`$`	`$`	Extension	
`7;`	7	7	Historical	
`7;5;`	5	5	Historical	
`7;5;9`	5	9	Historical	
`7;5,9`	5	9	Historical	
`7;$;4`	`$`	4	Historical	Valid, but erroneous.
`7;9`	7	9	Historical	
`7;+`	7	8	Historical	
`;`	`.`	`$`	Historical	
`;7`	`.`	7	Extension	
`;;`	`$`	`$`	Extension	
`;,`	`$`	`$`	Extension	

Historically, *ed* accepted the `'^'` character as an address, in which case it was identical to the <hyphen-minus> character. POSIX.1-2017 does not require or prohibit this behavior.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the OPTIONS section, the meaning of **–s** and – is clarified.

A second FUTURE DIRECTION is added.

Issue 6

The obsolescent single-minus form is removed.

A second APPLICATION USAGE note is added.

The Open Group Corrigendum U025/2 is applied, correcting the description of the Edit section.

The *ed* utility is updated to align with the IEEE P1003.2b draft standard. This includes addition of the treatment of the SIGQUIT signal, changes to *ed* addressing, and changes to processing when end-of-file is detected and when terminal disconnect is detected.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/22 is applied, adding the text: ``Any line modified by the *command list* shall be unmarked.'' to the **G** command. This change corresponds to a similar change made to the **g** command in the first version of this standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/7 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if an operand is `'–'`.

Austin Group Interpretation 1003.1-2001 #036 is applied, clarifying the behavior for BREs.

SD5-XCU-ERN-94 is applied, updating text in the EXTENDED DESCRIPTION where a terminal disconnect is detected (in Commands in *ed*).

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-135 is applied, removing some RATIONALE text that is no longer applicable.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0090 [584], XCU/TC2-2008/0091 [584], and XCU/TC2-2008/0092 [584] are applied.

NAME

env — set the environment for command invocation

SYNOPSIS

```
env [−i] [name=value]... [utility [argument...]]
```

DESCRIPTION

The *env* utility shall obtain the current environment, modify it according to its arguments, then invoke the utility named by the *utility* operand with the modified environment.

Optional arguments shall be passed to *utility*.

If no *utility* operand is specified, the resulting environment shall be written to the standard output, with one *name=value* pair per line.

If the first argument is `'−'`, the results are unspecified.

OPTIONS

The *env* utility shall conform to XBD Section 12.2 (on page 216), except for the unspecified usage of `'−'`.

The following options shall be supported:

−i Invoke *utility* with exactly the environment specified by the arguments; the inherited environment shall be ignored completely.

OPERANDS

The following operands shall be supported:

name=value Arguments of the form *name=value* shall modify the execution environment, and shall be placed into the inherited environment before the *utility* is invoked.

utility The name of the utility to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2384), the results are undefined.

argument A string to pass as an argument for the invoked utility.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *env*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

87921 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

87922 *PATH* Determine the location of the *utility*, as described in XBD Chapter 8 (on page 173).
87923 If *PATH* is specified as a *name=value* operand to *env*, the *value* given shall be used in
87924 the search for *utility*.

87925 **ASYNCHRONOUS EVENTS**
87926 Default.

87927 **STDOUT**
87928 If no *utility* operand is specified, each *name=value* pair in the resulting environment shall be
87929 written in the form:

87930 `"%s=%s\n", <name>, <value>`

87931 If the *utility* operand is specified, the *env* utility shall not write to standard output.

87932 **STDERR**
87933 The standard error shall be used only for diagnostic messages.

87934 **OUTPUT FILES**
87935 None.

87936 **EXTENDED DESCRIPTION**
87937 None.

87938 **EXIT STATUS**
87939 If *utility* is invoked, the exit status of *env* shall be the exit status of *utility*; otherwise, the *env*
87940 utility shall exit with one of the following values:

87941 0 The *env* utility completed successfully.

87942 1–125 An error occurred in the *env* utility.

87943 126 The utility specified by *utility* was found but could not be invoked.

87944 127 The utility specified by *utility* could not be found.

87945 **CONSEQUENCES OF ERRORS**
87946 Default.

87947 **APPLICATION USAGE**
87948 The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if
87949 an error occurs so that applications can distinguish ``failure to find a utility'' from ``invoked
87950 utility exited with an error indication''. The value 127 was chosen because it is not commonly
87951 used for other meanings; most utilities use small values for ``normal error conditions'' and the
87952 values above 128 can be confused with termination due to receipt of a signal. The value 126 was
87953 chosen in a similar manner to indicate that the utility could be found, but not invoked. Some
87954 scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction
87955 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
87956 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for
87957 any other reason.

87958 Historical implementations of the *env* utility use the *execvp*( ) or *execlp*( ) functions defined in the
87959 System Interfaces volume of POSIX.1-2017 to invoke the specified utility; this provides better
87960 performance and keeps users from having to escape characters with special meaning to the shell.
87961 Therefore, shell functions, special built-ins, and built-ins that are only provided by the shell are
87962 not found.

EXAMPLES

The following command:

```
env −i PATH=/mybin:"$PATH" $(getconf V7_ENV) mygrep xyz myfile
```

invokes the command *mygrep* with a new *PATH* value as the only entry in its environment other than any variables required by the implementation for conformance. In this case, *PATH* is used to locate *mygrep*, which is expected to reside in **/mybin**.

RATIONALE

As with all other utilities that invoke other utilities, this volume of POSIX.1-2017 only specifies what *env* does with standard input, standard output, standard error, input files, and output files. If a utility is executed, it is not constrained by the specification of input and output by *env*.

The **−i** option was added to allow the functionality of the removed − option in a manner compatible with the Utility Syntax Guidelines. It is possible to create a non-conforming environment using the **−i** option, as it may remove environment variables required by the implementation for conformance. The following will preserve these environment variables as well as preserve the *PATH* for conforming utilities:

```
IFS='
'
# The preceding value should be <space><tab><newline>.
# Set IFS to its default value.

set −f
# disable pathname expansion

\unalias −a
# Unset all possible aliases.
# Note that unalias is escaped to prevent an alias
# being used for unalias.
# This step is not strictly necessary, since aliases are not inherited,
# and the ENV environment variable is only used by interactive shells,
# the only way any aliases can exist in a script is if it defines them
# itself.

unset −f env getconf
# Ensure env and getconf are not user functions.

env −i $(getconf V7_ENV) PATH="$(getconf PATH)" command
```

Some have suggested that *env* is redundant since the same effect is achieved by:

```
name=value ... utility [ argument ... ]
```

The example is equivalent to *env* when an environment variable is being added to the environment of the command, but not when the environment is being set to the given value. The *env* utility also writes out the current environment if invoked without arguments. There is sufficient functionality beyond what the example provides to justify inclusion of *env*.

FUTURE DIRECTIONS

None.

SEE ALSO

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

88006 **CHANGE HISTORY**

88007 First released in Issue 2.

88008 **Issue 7**

88009 Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first
88010 argument is `'−'`.

88011 Austin Group Interpretation 1003.1-2001 #047 is applied, providing RATIONALE on how to use
88012 the *env* utility to preserve a conforming environment.

88013 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

88014 The EXAMPLES section is revised to change the use of *env* **−i**.

88015 **NAME**

88016 ex ‡’text editor

88017 **SYNOPSIS**

88018 UP `ex [-rR] [-s|-v] [-c command] [-t tagstring] [-w size] [file...]`

88019 **DESCRIPTION**

88020 The *ex* utility is a line-oriented text editor. There are two other modes of the editor ‡óopen and
88021 visual—in which screen-oriented editing is available. This is described more fully by the *ex* **open**
88022 and **visual** commands and in *vi*.

88023 If an operand is `'-'`, the results are unspecified.

88024 This section uses the term *edit buffer* to describe the current working text. No specific
88025 implementation is implied by this term. All editing changes are performed on the edit buffer,
88026 and no changes to it shall affect any file until an editor command writes the file.

88027 Certain terminals do not have all the capabilities necessary to support the complete *ex* definition,
88028 such as the full-screen editing commands (*visual mode* or *open mode*). When these commands
88029 cannot be supported on such terminals, this condition shall not produce an error message such
88030 as ``not an editor command'' or report a syntax error. The implementation may either accept the
88031 commands and produce results on the screen that are the result of an unsuccessful attempt to
88032 meet the requirements of this volume of POSIX.1-2017 or report an error describing the terminal-
88033 related deficiency.

88034 **OPTIONS**

88035 The *ex* utility shall conform to XBD Section 12.2 (on page 216), except for the unspecified usage
88036 of `'-'`, and that `'+'` may be recognized as an option delimiter as well as `'-'`.

88037 The following options shall be supported:

88038 **-c** *command* Specify an initial command to be executed in the first edit buffer loaded from an
88039 existing file (see the EXTENDED DESCRIPTION section). Implementations may
88040 support more than a single **-c** option. In such implementations, the specified
88041 commands shall be executed in the order specified on the command line.

88042 **-r** Recover the named files (see the EXTENDED DESCRIPTION section). Recovery
88043 information for a file shall be saved during an editor or system crash (for example,
88044 when the editor is terminated by a signal which the editor can catch), or after the
88045 use of an *ex* **preserve** command.

88046 A *crash* in this context is an unexpected failure of the system or utility that requires
88047 restarting the failed system or utility. A system crash implies that any utilities
88048 running at the time also crash. In the case of an editor or system crash, the number
88049 of changes to the edit buffer (since the most recent **preserve** command) that will be
88050 recovered is unspecified.

88051 If no *file* operands are given and the **-t** option is not specified, all other options, the
88052 *EXINIT* variable, and any **.exrc** files shall be ignored; a list of all recoverable files
88053 available to the invoking user shall be written, and the editor shall exit normally
88054 without further action.

88055 **-R** Set **readonly** edit option.

88056 **-s** Prepare *ex* for batch use by taking the following actions:

88057 Suppress writing prompts and informational (but not diagnostic) messages.

88058 Ignore the value of *TERM* and any implementation default terminal type and
88059 assume the terminal is a type incapable of supporting open or visual modes;
88060 see the **visual** command and the description of *vi*.

88061 Suppress the use of the *EXINIT* environment variable and the reading of any
88062 **.exrc** file; see the EXTENDED DESCRIPTION section.

88063 Suppress autoindentation, ignoring the value of the **autoindent** edit option.

88064 **−t** *tagstring* Edit the file containing the specified *tagstring*; see *ctags*. The tags feature
88065 represented by **−t** *tagstring* and the **tag** command is optional. It shall be provided
88066 on any system that also provides a conforming implementation of *ctags*; otherwise,
88067 the use of **−t** produces undefined results. On any system, it shall be an error to
88068 specify more than a single **−t** option.

88069 **−v** Begin in visual mode (see *vi*).

88070 **−w** *size* Set the value of the *window* editor option to *size*.

88071 **OPERANDS**

88072 The following operand shall be supported:

88073 *file* A pathname of a file to be edited.

88074 **STDIN**

88075 The standard input consists of a series of commands and input text, as described in the
88076 EXTENDED DESCRIPTION section. The implementation may limit each line of standard input
88077 to a length of {LINE_MAX}.

88078 If the standard input is not a terminal device, it shall be as if the **−s** option had been specified.

88079 If a read from the standard input returns an error, or if the editor detects an end-of-file condition
88080 from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

88081 **INPUT FILES**

88082 Input files shall be text files or files that would be text files except for an incomplete last line that
88083 is not longer than {LINE_MAX}−1 bytes in length and contains no NUL characters. By default,
88084 any incomplete last line shall be treated as if it had a trailing <newline>. The editing of other
88085 forms of files may optionally be allowed by *ex* implementations.

88086 The **.exrc** files and source files shall be text files consisting of *ex* commands; see the EXTENDED
88087 DESCRIPTION section.

88088 By default, the editor shall read lines from the files to be edited without interpreting any of those
88089 lines as any form of editor command.

88090 **ENVIRONMENT VARIABLES**

88091 The following environment variables shall affect the execution of *ex*:

88092 *COLUMNS* Override the system-selected horizontal screen size. See XBD Chapter 8 (on page
88093 173) for valid values and results when it is unset or null.

88094 *EXINIT* Determine a list of *ex* commands that are executed on editor start-up. See the
88095 EXTENDED DESCRIPTION section for more details of the initialization phase.

88096 *HOME* Determine a pathname of a directory that shall be searched for an editor start-up
88097 file named **.exrc**; see the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the classification of characters as uppercase or lowercase letters, the case conversion of letters, and the detection of word boundaries.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path for the shell command specified in the *ex* editor commands **!**, **shell**, **read**, and **write**, and the open and visual mode command **!**; see the description of command search and execution in Section 2.9.1.1 (on page 2367).

SHELL Determine the preferred command line interpreter for use as the default value of the **shell** edit option.

TERM Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

The following term is used in this and following sections to specify command and asynchronous event actions:

complete write
A complete write is a write of the entire contents of the edit buffer to a file of a type other than a terminal device, or the saving of the edit buffer caused by the user executing the *ex* **preserve** command. Writing the contents of the edit buffer to a temporary file that will be removed when the editor exits shall not be considered a complete write.

The following actions shall be taken upon receipt of signals:

SIGINT If the standard input is not a terminal device, *ex* shall not write the file or return to command or text input mode, and shall exit with a non-zero exit status.

Otherwise, if executing an open or visual text input mode command, *ex* in receipt of SIGINT shall behave identically to its receipt of the <ESC> character.

Otherwise:

1. If executing an *ex* text input mode command, all input lines that have been completely entered shall be resolved into the edit buffer, and any partially entered line shall be discarded.
2. If there is a currently executing command, it shall be aborted and a message displayed. Unless otherwise specified by the *ex* or *vi* command descriptions, it is unspecified whether any lines modified by the executing command appear modified, or as they were before being modified by the executing command, in the buffer.

   If the currently executing command was a motion command, its associated command shall be discarded.
3. If in open or visual command mode, the terminal shall be alerted.
4. The editor shall then return to command mode.

SIGCONT The screen shall be refreshed if in open or visual mode.

SIGHUP If the edit buffer has been modified since the last complete write, *ex* shall attempt to save the edit buffer so that it can be recovered later using the **–r** option or the *ex* **recover** command. The editor shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

SIGTERM Refer to SIGHUP.

The action taken for all other signals is unspecified.

STDOUT

The standard output shall be used only for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output from *ex* shall be text files.

EXTENDED DESCRIPTION

Only the *ex* mode of the editor is described in this section. See *vi* for additional editing capabilities available in *ex*.

When an error occurs, *ex* shall write a message. If the terminal supports a standout mode (such as inverse video), the message shall be written in standout mode. If the terminal does not support a standout mode, and the edit option **errorbells** is set, an alert action shall precede the error message.

By default, *ex* shall start in command mode, which shall be indicated by a **:** prompt; see the **prompt** command. Text input mode can be entered by the **append**, **insert**, or **change** commands; it can be exited (and command mode re-entered) by typing a <period> (`'.'`) alone at the beginning of a line.

88177 **Initialization in ex and vi**

88178 The following symbols are used in this and following sections to specify locations in the edit
88179 buffer:

88180 *alternate and current pathnames*
88181 Two pathnames, named *current* and *alternate*, are maintained by the editor. Any *ex*
88182 commands that take filenames as arguments shall set them as follows:

88183 1. If a *file* argument is specified to the *ex* **edit**, **ex**, or **recover** commands, or if an *ex* **tag**
88184 command replaces the contents of the edit buffer.

88185 a. If the command replaces the contents of the edit buffer, the current pathname
88186 shall be set to the *file* argument or the file indicated by the tag, and the
88187 alternate pathname shall be set to the previous value of the current pathname.

88188 b. Otherwise, the alternate pathname shall be set to the *file* argument.

88189 2. If a *file* argument is specified to the *ex* **next** command:

88190 a. If the command replaces the contents of the edit buffer, the current pathname
88191 shall be set to the first *file* argument, and the alternate pathname shall be set to
88192 the previous value of the current pathname.

88193 3. If a *file* argument is specified to the *ex* **file** command, the current pathname shall be
88194 set to the *file* argument, and the alternate pathname shall be set to the previous value
88195 of the current pathname.

88196 4. If a *file* argument is specified to the *ex* **read** and **write** commands (that is, when
88197 reading or writing a file, and not to the program named by the **shell** edit option), or a
88198 *file* argument is specified to the *ex* **xit** command:

88199 a. If the current pathname has no value, the current pathname shall be set to the
88200 *file* argument.

88201 b. Otherwise, the alternate pathname shall be set to the *file* argument.

88202 If the alternate pathname is set to the previous value of the current pathname when the
88203 current pathname had no previous value, then the alternate pathname shall have no value
88204 as a result.

88205 *current line*
88206 The line of the edit buffer referenced by the cursor. Each command description specifies the
88207 current line after the command has been executed, as the *current line value*. When the edit
88208 buffer contains no lines, the current line shall be zero; see Addressing in ex (on page 2703).

88209 *current column*
88210 The current display line column occupied by the cursor. (The columns shall be numbered
88211 beginning at 1.) Each command description specifies the current column after the command
88212 has been executed, as the *current column* value. This column is an *ideal* column that is
88213 remembered over the lifetime of the editor. The actual display line column upon which the
88214 cursor rests may be different from the current column; see the cursor positioning discussion
88215 in Command Descriptions in vi (on page 3376).

88216 *set to non-<blank>*
88217 A description for a current column value, meaning that the current column shall be set to
88218 the last display line column on which is displayed any part of the first non-<blank> of the
88219 line. If the line has no non-<blank> non-<newline> characters, the current column shall be
88220 set to the last display line column on which is displayed any part of the last non-<newline>

88221 character in the line. If the line is empty, the current column shall be set to column position
88222 1.

88223 The length of lines in the edit buffer may be limited to {LINE_MAX} bytes. In open and visual
88224 mode, the length of lines in the edit buffer may be limited to the number of characters that will
88225 fit in the display. If either limit is exceeded during editing, an error message shall be written. If
88226 either limit is exceeded by a line read in from a file, an error message shall be written and the
88227 edit session may be terminated.

88228 If the editor stops running due to any reason other than a user command, and the edit buffer has
88229 been modified since the last complete write, it shall be equivalent to a SIGHUP asynchronous
88230 event. If the system crashes, it shall be equivalent to a SIGHUP asynchronous event.

88231 During initialization (before the first file is copied into the edit buffer or any user commands
88232 from the terminal are processed) the following shall occur:

88233 1. If the environment variable *EXINIT* is set, the editor shall execute the *ex* commands
88234 contained in that variable.

88235 2. If the *EXINIT* variable is not set, and all of the following are true:

88236 a. The *HOME* environment variable is not null and not empty.

88237 b. The file **.exrc** in the directory referred to by the *HOME* environment variable:

88238 i. Exists

88239 ii. Is owned by the same user ID as the real user ID of the process or the
88240 process has appropriate privileges

88241 iii. Is not writable by anyone other than the owner

88242 the editor shall execute the *ex* commands contained in that file.

88243 3. If and only if all of the following are true:

88244 a. The current directory is not referred to by the *HOME* environment variable.

88245 b. A command in the *EXINIT* environment variable or a command in the **.exrc** file in
88246 the directory referred to by the *HOME* environment variable sets the editor option
88247 **exrc**.

88248 c. The **.exrc** file in the current directory:

88249 i. Exists

88250 ii. Is owned by the same user ID as the real user ID of the process, or by one of
88251 a set of implementation-defined user IDs

88252 iii. Is not writable by anyone other than the owner

88253 the editor shall attempt to execute the *ex* commands contained in that file.

88254 Lines in any **.exrc** file that are blank lines shall be ignored. If any **.exrc** file exists, but is not read
88255 for ownership or permission reasons, it shall be an error.

88256 After the *EXINIT* variable and any **.exrc** files are processed, the first file specified by the user
88257 shall be edited, as follows:

88258 1. If the user specified the **−t** option, the effect shall be as if the *ex* **tag** command was entered
88259 with the specified argument, with the exception that if tag processing does not result in a
88260 file to edit, the effect shall be as described in step 3. below.

2. Otherwise, if the user specified any command line *file* arguments, the effect shall be as if the *ex* **edit** command was entered with the first of those arguments as its *file* argument.
3. Otherwise, the effect shall be as if the *ex* **edit** command was entered with a nonexistent filename as its *file* argument. It is unspecified whether this action shall set the current pathname. In an implementation where this action does not set the current pathname, any editor command using the current pathname shall fail until an editor command sets the current pathname.

If the −**r** option was specified, the first time a file in the initial argument list or a file specified by the −**t** option is edited, if recovery information has previously been saved about it, that information shall be recovered and the editor shall behave as if the contents of the edit buffer have already been modified. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. If no recovery information about a file is available, an informational message to this effect shall be written, and the edit shall proceed as usual.

If the −**c** option was specified, the first time a file that already exists (including a file that might not exist but for which recovery information is available, when the −**r** option is specified) replaces or initializes the contents of the edit buffer, the current line shall be set to the last line of the edit buffer, the current column shall be set to non-<blank>, and the *ex* commands specified with the −**c** option shall be executed. In this case, the current line and current column shall not be set as described for the command associated with the replacement or initialization of the edit buffer contents. However, if the −**t** option or a **tag** command is associated with this action, the −**c** option commands shall be executed and then the movement to the tag shall be performed.

The current argument list shall initially be set to the filenames specified by the user on the command line. If no filenames are specified by the user, the current argument list shall be empty. If the −**t** option was specified, it is unspecified whether any filename resulting from tag processing shall be prepended to the current argument list. In the case where the filename is added as a prefix to the current argument list, the current argument list reference shall be set to that filename. In the case where the filename is not added as a prefix to the current argument list, the current argument list reference shall logically be located before the first of the filenames specified on the command line (for example, a subsequent *ex* **next** command shall edit the first filename from the command line). If the −**t** option was not specified, the current argument list reference shall be to the first of the filenames on the command line.

Addressing in ex

Addressing in *ex* relates to the current line and the current column; the address of a line is its 1-based line number, the address of a column is its 1-based count from the beginning of the line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. In each command description, the effect of the command on the current line number and the current column is described.

Addresses are constructed as follows:

1. The character `'.'` (period) shall address the current line.
2. The character `'$'` shall address the last line of the edit buffer.
3. The positive decimal number *n* shall address the *n*th line of the edit buffer.
4. The address `"'x"` refers to the line marked with the mark name character `'x'`, which shall be a lowercase letter from the portable character set, the backquote character, or the single-quote character. It shall be an error if the line that was marked is not currently

present in the edit buffer or the mark has not been set. Lines can be marked with the *ex* **mark** or **k** commands, or the *vi* **m** command.

5. A regular expression enclosed by <slash> characters (`'/'`) shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. As stated in Regular Expressions in ex (on page 2734), an address consisting of a null regular expression delimited by <slash> characters (`"//"`) shall address the next line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second <slash> can be omitted at the end of a command line. If the **wrapscan** edit option is set, the search shall wrap around to the beginning of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence `"\/"` shall represent a literal <slash> instead of the regular expression delimiter.

6. A regular expression enclosed in <question-mark> characters (`'?'`) shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. An address consisting of a null regular expression delimited by <question-mark> characters (`"??"`) shall address the previous line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second <question-mark> can be omitted at the end of a command line. If the **wrapscan** edit option is set, the search shall wrap around from the beginning of the edit buffer to the end of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence `"\?"` shall represent a literal <question-mark> instead of the RE delimiter.

7. A <plus-sign> (`'+'`) or a <hyphen-minus> (`'-'`) followed by a decimal number shall address the current line plus or minus the number. A `'+'` or `'-'` not followed by a decimal number shall address the current line plus or minus 1.

Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:

1. A `'+'` or `'-'` immediately followed by a decimal number shall add (subtract) the indicated number of lines to (from) the address. A `'+'` or `'-'` not followed by a decimal number shall add (subtract) 1 to (from) the address.

2. A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer.

Commands take zero, one, or two addresses; see the descriptions of *1addr* and *2addr* in Command Descriptions in ex (on page 2710). If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain.

Addresses shall be separated from each other by a <comma> (`','`) or a <semicolon> (`';'`). If no address is specified before or after a <comma> or <semicolon> separator, it shall be as if the address of the current line was specified before or after the separator. In the case of a <semicolon> separator, the current line (`'.'`) shall be set to the first address, and only then will

88354 the next address be calculated. This feature can be used to determine the starting line for
88355 forwards and backwards searches (see rules 5. and 6.).

88356 A <percent-sign> (`'%'`) shall be equivalent to entering the two addresses `"1,$"`.

88357 Any delimiting <blank> characters between addresses, address separators, or address offsets
88358 shall be discarded.

88359 **Command Line Parsing in ex**

88360 The following symbol is used in this and following sections to describe parsing behavior:

88361 *escape* If a character is referred to as ``<backslash>-escaped'' or ``<control>-V-escaped'', it
88362 shall mean that the character acquired or lost a special meaning by virtue of being
88363 preceded, respectively, by a <backslash> or <control>-V character. Unless
88364 otherwise specified, the escaping character shall be discarded at that time and shall
88365 not be further considered for any purpose.

88366 Command-line parsing shall be done in the following steps. For each step, characters already
88367 evaluated shall be ignored; that is, the phrase ``leading character'' refers to the next character
88368 that has not yet been evaluated.

88369 1. Leading <colon> characters shall be skipped.

88370 2. Leading <blank> characters shall be skipped.

88371 3. If the leading character is a double-quote character, the characters up to and including the
88372 next non-<backslash>-escaped <newline> shall be discarded, and any subsequent
88373 characters shall be parsed as a separate command.

88374 4. Leading characters that can be interpreted as addresses shall be evaluated; see
88375 Addressing in ex (on page 2703).

88376 5. Leading <blank> characters shall be skipped.

88377 6. If the next character is a <vertical-line> character or a <newline>:

88378 a. If the next character is a <newline>:

88379 i. If *ex* is in open or visual mode, the current line shall be set to the last
88380 address specified, if any.

88381 ii. Otherwise, if the last command was terminated by a <vertical-line>
88382 character, no action shall be taken; for example, the command
88383 `"||<newline>"` shall execute two implied commands, not three.

88384 iii. Otherwise, step 6.b. shall apply.

88385 b. Otherwise, the implied command shall be the **print** command. The last **#**, **p**, and **l**
88386 flags specified to any *ex* command shall be remembered and shall apply to this
88387 implied command. Executing the *ex* **number**, **print**, or **list** command shall set the
88388 remembered flags to **#**, nothing, and **l**, respectively, plus any other flags specified
88389 for that execution of the **number**, **print**, or **list** command.

88390 If *ex* is not currently performing a **global** or **v** command, and no address or count
88391 is specified, the current line shall be incremented by 1 before the command is
88392 executed. If incrementing the current line would result in an address past the last
88393 line in the edit buffer, the command shall fail, and the increment shall not happen.

88394 c. The <newline> or <vertical-line> character shall be discarded and any subsequent
88395 characters shall be parsed as a separate command.

88396 7. The command name shall be comprised of the next character (if the character is not
88397 alphabetic), or the next character and any subsequent alphabetic characters (if the
88398 character is alphabetic), with the following exceptions:

88399 a. Commands that consist of any prefix of the characters in the command name
88400 **delete**, followed immediately by any of the characters `'l'`, `'p'`, `'+'`, `'-'`, or `'#'`
88401 shall be interpreted as a **delete** command, followed by a <blank>, followed by the
88402 characters that were not part of the prefix of the **delete** command. The maximum
88403 number of characters shall be matched to the command name **delete**; for example,
88404 `"del"` shall not be treated as `"de"` followed by the flag **l**.

88405 b. Commands that consist of the character `'k'`, followed by a character that can be
88406 used as the name of a mark, shall be equivalent to the mark command followed by
88407 a <blank>, followed by the character that followed the `'k'`.

88408 c. Commands that consist of the character `'s'`, followed by characters that could be
88409 interpreted as valid options to the **s** command, shall be the equivalent of the **s**
88410 command, without any pattern or replacement values, followed by a <blank>,
88411 followed by the characters after the `'s'`.

88412 8. The command name shall be matched against the possible command names, and a
88413 command name that contains a prefix matching the characters specified by the user shall
88414 be the executed command. In the case of commands where the characters specified by the
88415 user could be ambiguous, the executed command shall be as follows:

88416
88417
88418
88419
88420
88421

a	**append**	**n**	**next**	**t**	**t**
c	**change**	**p**	**print**	**u**	**undo**
ch	**change**	**pr**	**print**	**un**	**undo**
e	**edit**	**r**	**read**	**v**	**v**
m	**move**	**re**	**read**	**w**	**write**
ma	**mark**	**s**	**s**		

88422 Implementation extensions with names causing similar ambiguities shall not be checked
88423 for a match until all possible matches for commands specified by POSIX.1-2017 have been
88424 checked.

88425 9. If the command is a **!** command, or if the command is a **read** command followed by zero
88426 or more <blank> characters and a **!**, or if the command is a **write** command followed by
88427 one or more <blank> characters and a **!**, the rest of the command shall include all
88428 characters up to a non-<backslash>-escaped <newline>. The <newline> shall be
88429 discarded and any subsequent characters shall be parsed as a separate *ex* command.

88430 10. Otherwise, if the command is an **edit**, **ex**, or **next** command, or a **visual** command while
88431 in open or visual mode, the next part of the command shall be parsed as follows:

88432 a. Any `'!'` character immediately following the command shall be skipped and be
88433 part of the command.

88434 b. Any leading <blank> characters shall be skipped and be part of the command.

88435 c. If the next character is a `'+'`, characters up to the first non-<backslash>-escaped
88436 <newline> or non-<backslash>-escaped <blank> shall be skipped and be part of
88437 the command.

88438 d. The rest of the command shall be determined by the steps specified in paragraph
88439 12.

88440 11. Otherwise, if the command is a **global**, **open**, **s**, or **v** command, the next part of the
88441 command shall be parsed as follows:

88442 a. Any leading <blank> characters shall be skipped and be part of the command.

88443 b. If the next character is not an alphanumeric, double-quote, <newline>,
88444 <backslash>, or <vertical-line> character:

88445 i. The next character shall be used as a command delimiter.

88446 ii. If the command is a **global**, **open**, or **v** command, characters up to the first
88447 non-<backslash>-escaped <newline>, or first non-<backslash>-escaped
88448 delimiter character, shall be skipped and be part of the command.

88449 iii. If the command is an **s** command, characters up to the first
88450 non-<backslash>-escaped <newline>, or second non-<backslash>-escaped
88451 delimiter character, shall be skipped and be part of the command.

88452 c. If the command is a **global** or **v** command, characters up to the first
88453 non-<backslash>-escaped <newline> shall be skipped and be part of the
88454 command.

88455 d. Otherwise, the rest of the command shall be determined by the steps specified in
88456 paragraph 12.

88457 12. Otherwise:

88458 a. If the command was a **map**, **unmap**, **abbreviate**, or **unabbreviate** command,
88459 characters up to the first non-<control>-V-escaped <newline>, <vertical-line>, or
88460 double-quote character shall be skipped and be part of the command.

88461 b. Otherwise, characters up to the first non-<backslash>-escaped <newline>,
88462 <vertical-line>, or double-quote character shall be skipped and be part of the
88463 command.

88464 c. If the command was an **append**, **change**, or **insert** command, and the step 12.b.
88465 ended at a <vertical-line> character, any subsequent characters, up to the next
88466 non-<backslash>-escaped <newline> shall be used as input text to the command.

88467 d. If the command was ended by a double-quote character, all subsequent characters,
88468 up to the next non-<backslash>-escaped <newline>, shall be discarded.

88469 e. The terminating <newline> or <vertical-line> character shall be discarded and any
88470 subsequent characters shall be parsed as a separate *ex* command.

88471 Command arguments shall be parsed as described by the Synopsis and Description of each
88472 individual *ex* command. This parsing shall not be <blank>-sensitive, except for the **!** argument,
88473 which must follow the command name without intervening <blank> characters, and where it
88474 would otherwise be ambiguous. For example, *count* and *flag* arguments need not be
88475 <blank>-separated because `"d22p"` is not ambiguous, but *file* arguments to the *ex* **next**
88476 command must be separated by one or more <blank> characters. Any <blank> in command
88477 arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands can be
88478 <control>-V-escaped, in which case the <blank> shall not be used as an argument delimiter. Any
88479 <blank> in the command argument for any other command can be <backslash>-escaped, in
88480 which case that <blank> shall not be used as an argument delimiter.

88481 Within command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands,

any character can be <control>-V-escaped. All such escaped characters shall be treated literally and shall have no special meaning. Within command arguments for all other *ex* commands that are not regular expressions or replacement strings, any character that would otherwise have a special meaning can be <backslash>-escaped. Escaped characters shall be treated literally, without special meaning as shell expansion characters or `'!'`, `'%'`, and `'#'` expansion characters. See Regular Expressions in ex (on page 2734) and Replacement Strings in ex (on page 2735) for descriptions of command arguments that are regular expressions or replacement strings.

Non-<backslash>-escaped `'%'` characters appearing in *file* arguments to any *ex* command shall be replaced by the current pathname; unescaped `'#'` characters shall be replaced by the alternate pathname. It shall be an error if `'%'` or `'#'` characters appear unescaped in an argument and their corresponding values are not set.

Non-<backslash>-escaped `'!'` characters in the arguments to either the *ex* **!** command or the open and visual mode **!** command, or in the arguments to the *ex* **read** command, where the first non-<blank> after the command name is a `'!'` character, or in the arguments to the *ex* **write** command where the command name is followed by one or more <blank> characters and the first non-<blank> after the command name is a `'!'` character, shall be replaced with the arguments to the last of those three commands as they appeared after all unescaped `'%'`, `'#'`, and `'!'` characters were replaced. It shall be an error if `'!'` characters appear unescaped in one of these commands and there has been no previous execution of one of these commands.

If an error occurs during the parsing or execution of an *ex* command:

> An informational message to this effect shall be written. Execution of the *ex* command shall stop, and the cursor (for example, the current line and column) shall not be further modified.
>
> If the *ex* command resulted from a map expansion, all characters from that map expansion shall be discarded, except as otherwise specified by the **map** command.
>
> Otherwise, if the *ex* command resulted from the processing of an *EXINIT* environment variable, a **.exrc** file, a **:source** command, a **−c** option, or a **+***command* specified to an *ex* **edit**, **ex**, **next**, or **visual** command, no further commands from the source of the commands shall be executed.
>
> Otherwise, if the *ex* command resulted from the execution of a buffer or a **global** or **v** command, no further commands caused by the execution of the buffer or the **global** or **v** command shall be executed.
>
> Otherwise, if the *ex* command was not terminated by a <newline>, all characters up to and including the next non-<backslash>-escaped <newline> shall be discarded.

Input Editing in ex

The following symbol is used in this and the following sections to specify command actions:

word In the POSIX locale, a word consists of a maximal sequence of letters, digits, and underscores, delimited at both ends by characters other than letters, digits, or underscores, or by the beginning or end of a line or the edit buffer.

When accepting input characters from the user, in either *ex* command mode or *ex* text input mode, *ex* shall enable canonical mode input processing, as defined in the System Interfaces volume of POSIX.1-2017.

88525 If in *ex* text input mode:

88526 1. If the **number** edit option is set, *ex* shall prompt for input using the line number that
88527 would be assigned to the line if it is entered, in the format specified for the *ex* **number**
88528 command.

88529 2. If the **autoindent** edit option is set, *ex* shall prompt for input using **autoindent** characters,
88530 as described by the **autoindent** edit option. **autoindent** characters shall follow the line
88531 number, if any.

88532 If in *ex* command mode:

88533 1. If the **prompt** edit option is set, input shall be prompted for using a single `':'` character;
88534 otherwise, there shall be no prompt.

88535 The input characters in the following sections shall have the following effects on the input line.

88536 **Scroll**

88537 *Synopsis*: `eof`

88538 See the description of the *stty eof* character in *stty*.

88539 If in *ex* command mode:

88540 If the *eof* character is the first character entered on the line, the line shall be evaluated as if
88541 it contained two characters: a <control>-D and a <newline>.

88542 Otherwise, the *eof* character shall have no special meaning.

88543 If in *ex* text input mode:

88544 If the cursor follows an **autoindent** character, the **autoindent** characters in the line shall be
88545 modified so that a part of the next text input character will be displayed on the first
88546 column in the line after the previous **shiftwidth** edit option column boundary, and the
88547 user shall be prompted again for input for the same line.

88548 Otherwise, if the cursor follows a `'0'`, which follows an **autoindent** character, and the `'0'`
88549 was the previous text input character, the `'0'` and all **autoindent** characters in the line
88550 shall be discarded, and the user shall be prompted again for input for the same line.

88551 Otherwise, if the cursor follows a `'^'`, which follows an **autoindent** character, and the `'^'`
88552 was the previous text input character, the `'^'` and all **autoindent** characters in the line
88553 shall be discarded, and the user shall be prompted again for input for the same line. In
88554 addition, the **autoindent** level for the next input line shall be derived from the same line
88555 from which the **autoindent** level for the current input line was derived.

88556 Otherwise, if there are no **autoindent** or text input characters in the line, the *eof* character
88557 shall be discarded.

88558 Otherwise, the *eof* character shall have no special meaning.

88559 **<newline>**

88560 *Synopsis*: `<newline>`
88561 `<control>-J`

88562 If in *ex* command mode:

88563 Cause the command line to be parsed; <control>-J shall be mapped to the <newline> for
88564 this purpose.

88565 If in *ex* text input mode:

88566 Terminate the current line. If there are no characters other than **autoindent** characters on
88567 the line, all characters on the line shall be discarded.

88568 Prompt for text input on a new line after the current line. If the **autoindent** edit option is
88569 set, an appropriate number of **autoindent** characters shall be added as a prefix to the line
88570 as described by the *ex* **autoindent** edit option.

88571 **<backslash>**

88572 *Synopsis*: `<backslash>`

88573 Allow the entry of a subsequent <newline> or <control>-J as a literal character, removing any
88574 special meaning that it may have to the editor during text input mode. The <backslash>
88575 character shall be retained and evaluated when the command line is parsed, or retained and
88576 included when the input text becomes part of the edit buffer.

88577 **<control>-V**

88578 *Synopsis*: `<control>-V`

88579 Allow the entry of any subsequent character as a literal character, removing any special meaning
88580 that it may have to the editor during text input mode. The <control>-V character shall be
88581 discarded before the command line is parsed or the input text becomes part of the edit buffer.

88582 If the ``literal next'' functionality is performed by the underlying system, it is implementation-
88583 defined whether a character other than <control>-V performs this function.

88584 **<control>-W**

88585 *Synopsis*: `<control>-W`

88586 Discard the <control>-W, and the word previous to it in the input line, including any <blank>
88587 characters following the word and preceding the <control>-W. If the ``word erase'' functionality
88588 is performed by the underlying system, it is implementation-defined whether a character other
88589 than <control>-W performs this function.

88590 **Command Descriptions in ex**

88591 The following symbols are used in this section to represent command modifiers. Some of these
88592 modifiers can be omitted, in which case the specified defaults shall be used.

88593 *1addr* A single line address, given in any of the forms described in Addressing in ex (on
88594 page 2703); the default shall be the current line (`'.'`), unless otherwise specified.

88595 If the line address is zero, it shall be an error, unless otherwise specified in the
88596 following command descriptions.

If the edit buffer is empty, and the address is specified with a command other than **=**, **append**, **insert**, **open**, **put**, **read**, or **visual**, or the address is not zero, it shall be an error.

2addr Two addresses specifying an inclusive range of lines. If no addresses are specified, the default for *2addr* shall be the current line only (`".,."`), unless otherwise specified in the following command descriptions. If one address is specified, *2addr* shall specify that line only, unless otherwise specified in the following command descriptions.

It shall be an error if the first address is greater than the second address.

If the edit buffer is empty, and the two addresses are specified with a command other than the **!**, **write**, **wq**, or **xit** commands, or either address is not zero, it shall be an error.

count A positive decimal number. If *count* is specified, it shall be equivalent to specifying an additional address to the command, unless otherwise specified by the following command descriptions. The additional address shall be equal to the last address specified to the command (either explicitly or by default) plus *count*−1.

If this would result in an address greater than the last line of the edit buffer, it shall be corrected to equal the last line of the edit buffer.

flags One or more of the characters `'+'`, `'−'`, `'#'`, `'p'`, or `'l'` (ell). The flag characters can be <blank>-separated, and in any order or combination. The characters `'#'`, `'p'`, and `'l'` shall cause lines to be written in the format specified by the **print** command with the specified *flags*.

The lines to be written are as follows:

1. All edit buffer lines written during the execution of the *ex* **&**, **~**, **list**, **number**, **open**, **print**, **s**, **visual**, and **z** commands shall be written as specified by *flags*.
2. After the completion of an *ex* command with a flag as an argument, the current line shall be written as specified by *flags*, unless the current line was the last line written by the command.

The characters `'+'` and `'−'` cause the value of the current line after the execution of the *ex* command to be adjusted by the offset address as described in Addressing in ex (on page 2703). This adjustment shall occur before the current line is written as described in 2. above.

The default for *flags* shall be none.

buffer One of a number of named areas for holding text. The named buffers are specified by the alphanumeric characters of the POSIX locale. There shall also be one ``unnamed'' buffer. When no buffer is specified for editor commands that use a buffer, the unnamed buffer shall be used. Commands that store text into buffers shall store the text as it was before the command took effect, and shall store text occurring earlier in the file before text occurring later in the file, regardless of how the text region was specified. Commands that store text into buffers shall store the text into the unnamed buffer as well as any specified buffer.

In *ex* commands, buffer names are specified as the name by itself. In open or visual mode commands the name is preceded by a double-quote (`'"'`) character.

If the specified buffer name is an uppercase character, and the buffer contents are to be modified, the buffer shall be appended to rather than being overwritten. If

the buffer is not being modified, specifying the buffer name in lowercase and uppercase shall have identical results.

There shall also be buffers named by the numbers 1 through 9. In open and visual mode, if a region of text including characters from more than a single line is being modified by the *vi* **c** or **d** commands, the motion character associated with the **c** or **d** commands specifies that the buffer text shall be in line mode, or the commands **%**, **`**, **/**, **?**, **(**, **)**, **N**, **n**, **{**, or **}** are used to define a region of text for the **c** or **d** commands, the contents of buffers 1 through 8 shall be moved into the buffer named by the next numerically greater value, the contents of buffer 9 shall be discarded, and the region of text shall be copied into buffer 1. This shall be in addition to copying the text into a user-specified buffer or unnamed buffer, or both. Numeric buffers can be specified as a source buffer for open and visual mode commands; however, specifying a numeric buffer as the write target of an open or visual mode command shall have unspecified results.

The text of each buffer shall have the characteristic of being in either line or character mode. Appending text to a non-empty buffer shall set the mode to match the characteristic of the text being appended. Appending text to a buffer shall cause the creation of at least one additional line in the buffer. All text stored into buffers by *ex* commands shall be in line mode. The *ex* commands that use buffers as the source of text specify individually how buffers of different modes are handled. Each open or visual mode command that uses buffers for any purpose specifies individually the mode of the text stored into the buffer and how buffers of different modes are handled.

file Command text used to derive a pathname. The default shall be the current pathname, as defined previously, in which case, if no current pathname has yet been established it shall be an error, except where specifically noted in the individual command descriptions that follow. If the command text contains any of the characters `'~'`, `'{'`, `'['`, `'*'`, `'?'`, `'$'`, `'"'`, backquote, single-quote, and <backslash>, it shall be subjected to the process of ``shell expansions'', as described below; if more than a single pathname results and the command expects only one, it shall be an error.

The process of shell expansions in the editor shall be done as follows. The *ex* utility shall pass two arguments to the program named by the shell edit option; the first shall be **−c**, and the second shall be the string `"echo"` and the command text as a single argument. The standard output and standard error of that command shall replace the command text.

! A character that can be appended to the command name to modify its operation, as detailed in the individual command descriptions. With the exception of the *ex* **read**, **write**, and **!** commands, the `'!'` character shall only act as a modifier if there are no <blank> characters between it and the command name.

remembered search direction

The *vi* commands **N** and **n** begin searching in a forwards or backwards direction in the edit buffer based on a remembered search direction, which is initially unset, and is set by the *ex* **global**, **v**, **s**, and **tag** commands, and the *vi* **/** and **?** commands.

88686 **Abbreviate**

88687 *Synopsis*: `ab[breviate][lhs rhs]`

88688 If *lhs* and *rhs* are not specified, write the current list of abbreviations and do nothing more.

88689 Implementations may restrict the set of characters accepted in *lhs* or *rhs*, except that printable
88690 characters and <blank> characters shall not be restricted. Additional restrictions shall be
88691 implementation-defined.

88692 In both *lhs* and *rhs*, any character may be escaped with a <control>-V, in which case the character
88693 shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

88694 In open and visual text input mode, if a non-word or <ESC> character that is not escaped by a
88695 <control>-V character is entered after a word character, a check shall be made for a set of
88696 characters matching *lhs*, in the text input entered during this command. If it is found, the effect
88697 shall be as if *rhs* was entered instead of *lhs*.

88698 The set of characters that are checked is defined as follows:

88699 1. If there are no characters inserted before the word and non-word or <ESC> characters
88700 that triggered the check, the set of characters shall consist of the word character.

88701 2. If the character inserted before the word and non-word or <ESC> characters that
88702 triggered the check is a word character, the set of characters shall consist of the characters
88703 inserted immediately before the triggering characters that are word characters, plus the
88704 triggering word character.

88705 3. If the character inserted before the word and non-word or <ESC> characters that
88706 triggered the check is not a word character, the set of characters shall consist of the
88707 characters that were inserted before the triggering characters that are neither <blank>
88708 characters nor word characters, plus the triggering word character.

88709 It is unspecified whether the *lhs* argument entered for the *ex* **abbreviate** and **unabbreviate**
88710 commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the
88711 effect of the command shall be as if the replacement had not occurred.

88712 *Current line*: Unchanged.

88713 *Current column*: Unchanged.

88714 **Append**

88715 *Synopsis*: `[laddr] a[ppend][!]`

88716 Enter *ex* text input mode; the input text shall be placed after the specified line. If line zero is
88717 specified, the text shall be placed at the beginning of the edit buffer.

88718 This command shall be affected by the **number** and **autoindent** edit options; following the
88719 command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the
88720 duration of this command only.

88721 *Current line*: Set to the last input line; if no lines were input, set to the specified line, or to the first
88722 line of the edit buffer if a line of zero was specified, or zero if the edit buffer is empty.

88723 *Current column*: Set to non-<blank>.

88724 **Arguments**

88725 *Synopsis*: `ar[gs]`

88726 Write the current argument list, with the current argument-list entry, if any, between `'['` and
88727 `']'` characters.

88728 *Current line*: Unchanged.

88729 *Current column*: Unchanged.

88730 **Change**

88731 *Synopsis*: `[2addr] c[hange][!][count]`

88732 Enter *ex* text input mode; the input text shall replace the specified lines. The specified lines shall
88733 be copied into the unnamed buffer, which shall become a line mode buffer.

88734 This command shall be affected by the **number** and **autoindent** edit options; following the
88735 command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the
88736 duration of this command only.

88737 *Current line*: Set to the last input line; if no lines were input, set to the line before the first
88738 address, or to the first line of the edit buffer if there are no lines preceding the first address, or to
88739 zero if the edit buffer is empty.

88740 *Current column*: Set to non-<blank>.

88741 **Change Directory**

88742 *Synopsis*: `chd[ir][!][directory]`
88743 `cd[!][directory]`

88744 Change the current working directory to *directory*.

88745 If no *directory* argument is specified, and the *HOME* environment variable is set to a non-null
88746 and non-empty value, *directory* shall default to the value named in the *HOME* environment
88747 variable. If the *HOME* environment variable is empty or is undefined, the default value of
88748 *directory* is implementation-defined.

88749 If no `'!'` is appended to the command name, and the edit buffer has been modified since the
88750 last complete write, and the current pathname does not begin with a `'/'`, it shall be an error.

88751 *Current line*: Unchanged.

88752 *Current column*: Unchanged.

88753 **Copy**

88754 *Synopsis*: `[2addr] co[py] 1addr [flags]`
88755 `[2addr] t 1addr [flags]`

88756 Copy the specified lines after the specified destination line; line zero specifies that the lines shall
88757 be placed at the beginning of the edit buffer.

88758 *Current line*: Set to the last line copied.

88759 *Current column*: Set to non-<blank>.

88760 **Delete**

88761 *Synopsis*: **[***2addr***]** d**[**elete**][***buffer***][***count***][***flags***]**

88762 Delete the specified lines into a buffer (defaulting to the unnamed buffer), which shall become a
88763 line-mode buffer.

88764 Flags can immediately follow the command name; see Command Line Parsing in ex (on page
88765 2705).

88766 *Current line*: Set to the line following the deleted lines, or to the last line in the edit buffer if that
88767 line is past the end of the edit buffer, or to zero if the edit buffer is empty.

88768 *Current column*: Set to non-<blank>.

88769 **Edit**

88770 *Synopsis*: e**[**dit**][**!**][**+*command***][***file***]**
88771 ex**[**!**][**+*command***][***file***]**

88772 If no '!' is appended to the command name, and the edit buffer has been modified since the
88773 last complete write, it shall be an error.

88774 If *file* is specified, replace the current contents of the edit buffer with the current contents of *file*,
88775 and set the current pathname to *file*. If *file* is not specified, replace the current contents of the
88776 edit buffer with the current contents of the file named by the current pathname. If for any reason
88777 the current contents of the file cannot be accessed, the edit buffer shall be empty.

88778 The +*command* option shall be <blank>-delimited; <blank> characters within the +*command* can
88779 be escaped by preceding them with a <backslash> character. The +*command* shall be interpreted
88780 as an *ex* command immediately after the contents of the edit buffer have been replaced and the
88781 current line and column have been set.

88782 If the edit buffer is empty:

88783 *Current line*: Set to 0.

88784 *Current column*: Set to 1.

88785 Otherwise, if executed while in *ex* command mode or if the +*command* argument is specified:

88786 *Current line*: Set to the last line of the edit buffer.

88787 *Current column*: Set to non-<blank>.

88788 Otherwise, if *file* is omitted or results in the current pathname:

88789 *Current line*: Set to the first line of the edit buffer.

88790 *Current column*: Set to non-<blank>.

88791 Otherwise, if *file* is the same as the last file edited, the line and column shall be set as follows; if
88792 the file was previously edited, the line and column may be set as follows:

88793 *Current line*: Set to the last value held when that file was last edited. If this value is not a valid
88794 line in the new edit buffer, set to the first line of the edit buffer.

88795 *Current column*: If the current line was set to the last value held when the file was last edited, set
88796 to the last value held when the file was last edited. Otherwise, or if the last value is not a valid
88797 column in the new edit buffer, set to non-<blank>.

Otherwise:

Current line: Set to the first line of the edit buffer.

Current column: Set to non-<blank>.

File

Synopsis: `f[ile][`*`file`*`]`

If a *file* argument is specified, the alternate pathname shall be set to the current pathname, and the current pathname shall be set to *file*.

Write an informational message. If the file has a current pathname, it shall be included in this message; otherwise, the message shall indicate that there is no current pathname. If the edit buffer contains lines, the current line number and the number of lines in the edit buffer shall be included in this message; otherwise, the message shall indicate that the edit buffer is empty. If the edit buffer has been modified since the last complete write, this fact shall be included in this message. If the **readonly** edit option is set, this fact shall be included in this message. The message may contain other unspecified information.

Current line: Unchanged.

Current column: Unchanged.

Global

Synopsis: `[`*`2addr`*`] g[lobal] /`*`pattern`*`/ [`*`commands`*`]`
`[`*`2addr`*`] v /`*`pattern`*`/ [`*`commands`*`]`

The optional `'!'` character after the **global** command shall be the same as executing the **v** command.

If *pattern* is empty (for example, `"//"`) or not specified, the last regular expression used in the editor command shall be used as the *pattern*. The *pattern* can be delimited by <slash> characters (shown in the Synopsis), as well as any non-alphanumeric or non-<blank> other than <backslash>, <vertical-line>, <newline>, or double-quote.

If no lines are specified, the lines shall default to the entire file.

The **global** and **v** commands are logically two-pass operations. First, mark the lines within the specified lines for which the line excluding the terminating <newline> matches (**global**) or does not match (**v** or **global!**) the specified pattern. Second, execute the *ex* commands given by *commands*, with the current line (`'.'`) set to each marked line. If an error occurs during this process, or the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error message shall be written and no more commands resulting from the execution of this command shall be processed.

Multiple *ex* commands can be specified by entering multiple commands on a single line using a <vertical-line> to delimit them, or one per line, by escaping each <newline> with a <backslash>.

If no commands are specified:

1. If in *ex* command mode, it shall be as if the **print** command were specified.
2. Otherwise, no command shall be executed.

For the **append**, **change**, and **insert** commands, the input text shall be included as part of the command, and the terminating <period> can be omitted if the command ends the list of commands. The **open** and **visual** commands can be specified as one of the commands, in which

case each marked line shall cause the editor to enter open or visual mode. If open or visual mode is exited using the *vi* **Q** command, the current line shall be set to the next marked line, and open or visual mode reentered, until the list of marked lines is exhausted.

The **global**, **v**, and **undo** commands cannot be used in *commands*. Marked lines may be deleted by commands executed for lines occurring earlier in the file than the marked lines. In this case, no commands shall be executed for the deleted lines.

If the remembered search direction is not set, the **global** and **v** commands shall set it to forward.

The **autoprint** and **autoindent** edit options shall be inhibited for the duration of the **g** or **v** command.

Current line: If no commands executed, set to the last marked line. Otherwise, as specified for the executed *ex* commands.

Current column: If no commands are executed, set to non-<blank>; otherwise, as specified for the individual *ex* commands.

Insert

Synopsis: **[***1addr***]** i**[**nsert**][**!**]**

Enter *ex* text input mode; the input text shall be placed before the specified line. If the line is zero or 1, the text shall be placed at the beginning of the edit buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with '!' shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the line before the specified line, or to the first line of the edit buffer if there are no lines preceding the specified line, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Join

Synopsis: **[***2addr***]** j**[**oin**][**!**][***count***][***flags***]**

If *count* is specified:

> If no address was specified, the **join** command shall behave as if *2addr* were the current line and the current line plus *count* (*.*,*.* + *count*).
>
> If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the specified address plus *count* (*addr*,*addr* + *count*).
>
> If two addresses were specified, the **join** command shall behave as if an additional address, equal to the last address plus *count* −1 (*addr1*,*addr2*,*addr2* + *count* −1), was specified.
>
> If this would result in a second address greater than the last line of the edit buffer, it shall be corrected to be equal to the last line of the edit buffer.

If no *count* is specified:

88876 If no address was specified, the **join** command shall behave as if *2addr* were the current
88877 line and the next line (. , . +1).

88878 If one address was specified, the **join** command shall behave as if *2addr* were the specified
88879 address and the next line (*addr*,*addr* +1).

88880 Join the text from the specified lines together into a single line, which shall replace the specified
88881 lines.

88882 If a `'!'` character is appended to the command name, the **join** shall be without modification of
88883 any line, independent of the current locale.

88884 Otherwise, in the POSIX locale, set the current line to the first of the specified lines, and then, for
88885 each subsequent line, proceed as follows:

88886 1. Discard leading <space> characters from the line to be joined.
88887 2. If the line to be joined is now empty, delete it, and skip steps 3 through 5.
88888 3. If the current line ends in a <blank>, or the first character of the line to be joined is a `')'`
88889 character, join the lines without further modification.
88890 4. If the last character of the current line is a `'.'`, join the lines with two <space> characters
88891 between them.
88892 5. Otherwise, join the lines with a single <space> between them.

88893 *Current line*: Set to the first line specified.

88894 *Current column*: Set to non-<blank>.

88895 **List**

88896 *Synopsis*: **[***2addr***]** l**[**ist**][***count***][***flags***]**

88897 This command shall be equivalent to the *ex* command:

88898 **[***2addr***]** p**[**rint**][***count***]** l**[***flags***]**

88899 See Print (on page 2722).

88900 **Map**

88901 *Synopsis*: map**[**!**][***lhs rhs***]**

88902 If *lhs* and *rhs* are not specified:

88903 1. If `'!'` is specified, write the current list of text input mode maps.
88904 2. Otherwise, write the current list of command mode maps.
88905 3. Do nothing more.

88906 Implementations may restrict the set of characters accepted in *lhs* or *rhs*, except that printable
88907 characters and <blank> characters shall not be restricted. Additional restrictions shall be
88908 implementation-defined. In both *lhs* and *rhs*, any character can be escaped with a <control>-V, in
88909 which case the character shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V
88910 shall be discarded.

88911 If the character `'!'` is appended to the **map** command name, the mapping shall be effective
88912 during open or visual text input mode rather than **open** or **visual** command mode. This allows
88913 *lhs* to have two different **map** definitions at the same time: one for command mode and one for

text input mode.

For command mode mappings:

When the *lhs* is entered as any part of a *vi* command in open or visual mode (but not as part of the arguments to the command), the action shall be as if the corresponding *rhs* had been entered.

If any character in the command, other than the first, is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.

It is unspecified whether implementations shall support **map** commands where the *lhs* is more than a single character in length, where the first character of the *lhs* is printable.

If *lhs* contains more than one character and the first character is `'#'`, followed by a sequence of digits corresponding to a numbered function key, then when this function key is typed it shall be mapped to *rhs*. Characters other than digits following a `'#'` character also represent the function key named by the characters in the *lhs* following the `'#'` and may be mapped to *rhs*. It is unspecified how function keys are named or what function keys are supported.

For text input mode mappings:

When the *lhs* is entered as any part of text entered in open or visual text input modes, the action shall be as if the corresponding *rhs* had been entered.

If any character in the input text is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.

It is unspecified whether the *lhs* text entered for subsequent **map** or **unmap** commands is replaced with the *rhs* text for the purposes of the screen display; regardless of whether or not the display appears as if the corresponding *rhs* text was entered, the effect of the command shall be as if the *lhs* text was entered.

If only part of the *lhs* is entered, it is unspecified how long the editor will wait for additional, possibly matching characters before treating the already entered characters as not matching the *lhs*.

The *rhs* characters shall themselves be subject to remapping, unless otherwise specified by the **remap** edit option, except that if the characters in *lhs* occur as prefix characters in *rhs*, those characters shall not be remapped.

On block-mode terminals, the mapping need not occur immediately (for example, it may occur after the terminal transmits a group of characters to the system), but it shall achieve the same results as if it occurred immediately.

Current line: Unchanged.

Current column: Unchanged.

88949 **Mark**

88950 *Synopsis*: `[`*laddr*`] ma[rk] `*character*
88951 `[`*laddr*`] k `*character*

88952 Implementations shall support *character* values of a single lowercase letter of the POSIX locale
88953 and the backquote and single-quote characters; support of other characters is implementation-
88954 defined.

88955 If executing the *vi* **m** command, set the specified mark to the current line and 1-based numbered
88956 character referenced by the current column, if any; otherwise, column position 1.

88957 Otherwise, set the specified mark to the specified line and 1-based numbered first non-<blank>
88958 non-<newline> in the line, if any; otherwise, the last non-<newline> in the line, if any;
88959 otherwise, column position 1.

88960 The mark shall remain associated with the line until the mark is reset or the line is deleted. If a
88961 deleted line is restored by a subsequent **undo** command, any marks previously associated with
88962 the line, which have not been reset, shall be restored as well. Any use of a mark not associated
88963 with a current line in the edit buffer shall be an error.

88964 The marks ` and ' shall be set as described previously, immediately before the following events
88965 occur in the editor:

88966 1. The use of `'$'` as an *ex* address
88967 2. The use of a positive decimal number as an *ex* address
88968 3. The use of a search command as an *ex* address
88969 4. The use of a mark reference as an *ex* address
88970 5. The use of the following open and visual mode commands: <control>-], %, **(**, **)**, [,], {, }
88971 6. The use of the following open and visual mode commands: **'**, **G**, **H**, **L**, **M**, **z** if the current
88972 line will change as a result of the command
88973 7. The use of the open and visual mode commands: **/**, **?**, **N**, **`**, **n** if the current line or column
88974 will change as a result of the command
88975 8. The use of the *ex* mode commands: **z**, **undo**, **global**, **v**

88976 For rules 1., 2., 3., and 4., the ` and ' marks shall not be set if the *ex* command is parsed as
88977 specified by rule 6.a. in Command Line Parsing in ex (on page 2705).

88978 For rules 5., 6., and 7., the ` and ' marks shall not be set if the commands are used as motion
88979 commands in open and visual mode.

88980 For rules 1., 2., 3., 4., 5., 6., 7., and 8., the ` and ' marks shall not be set if the command fails.

88981 The ` and ' marks shall be set as described previously, each time the contents of the edit buffer
88982 are replaced (including the editing of the initial buffer), if in open or visual mode, or if in **ex**
88983 mode and the edit buffer is not empty, before any commands or movements (including
88984 commands or movements specified by the **−c** or **−t** options or the **+***command* argument) are
88985 executed on the edit buffer. If in open or visual mode, the marks shall be set as if executing the *vi*
88986 **m** command; otherwise, as if executing the *ex* **mark** command.

88987 When changing from **ex** mode to open or visual mode, if the ` and ' marks are not already set,
88988 the ` and ' marks shall be set as described previously.

88989 *Current line*: Unchanged.

Current column: Unchanged.

Move

Synopsis: `[`*2addr*`] m[ove] `*1addr*` [`*flags*`]`

Move the specified lines after the specified destination line. A destination of line zero specifies that the lines shall be placed at the beginning of the edit buffer. It shall be an error if the destination line is within the range of lines to be moved.

Current line: Set to the last of the moved lines.

Current column: Set to non-<blank>.

Next

Synopsis: `n[ext][!][+`*command*`][`*file ...*`]`

If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If one or more files is specified:

1. Set the argument list to the specified filenames.
2. Set the current argument list reference to be the first entry in the argument list.
3. Set the current pathname to the first filename specified.

Otherwise:

1. It shall be an error if there are no more filenames in the argument list after the filename currently referenced.
2. Set the current pathname and the current argument list reference to the filename after the filename currently referenced in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

The **+***command* option shall be <blank>-delimited; <blank> characters can be escaped by preceding them with a <backslash> character. The **+***command* shall be interpreted as an *ex* command immediately after the contents of the edit buffer have been replaced and the current line and column have been set.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

89022 **Number**

89023 *Synopsis*: **[***2addr***]** nu**[**mber**][***count***][***flags***]**
89024 **[***2addr***]** #**[***count***][***flags***]**

89025 These commands shall be equivalent to the *ex* command:

89026 **[***2addr***]** p**[**rint**][***count***]** #**[***flags***]**

89027 See Print.

89028 **Open**

89029 *Synopsis*: **[***1addr***]** o**[**pen**]** */pattern/* **[***flags***]**

89030 This command need not be supported on block-mode terminals or terminals with insufficient
89031 capabilities. If standard input, standard output, or standard error are not terminal devices, the
89032 results are unspecified.

89033 Enter open mode.

89034 The trailing delimiter can be omitted from *pattern* at the end of the command line. If *pattern* is
89035 empty (for example, "//") or not specified, the last regular expression used in the editor shall
89036 be used as the pattern. The pattern can be delimited by <slash> characters (shown in the
89037 Synopsis), as well as any alphanumeric, or non-<blank> other than <backslash>, <vertical-line>,
89038 <newline>, or double-quote.

89039 *Current line*: Set to the specified line.

89040 *Current column*: Set to non-<blank>.

89041 **Preserve**

89042 *Synopsis*: pre**[**serve**]**

89043 Save the edit buffer in a form that can later be recovered by using the **−r** option or by using the
89044 *ex* **recover** command. After the file has been preserved, a mail message shall be sent to the user.
89045 This message shall be readable by invoking the *mailx* utility. The message shall contain the name
89046 of the file, the time of preservation, and an *ex* command that could be used to recover the file.
89047 Additional information may be included in the mail message.

89048 *Current line*: Unchanged.

89049 *Current column*: Unchanged.

89050 **Print**

89051 *Synopsis*: **[***2addr***]** p**[**rint**][***count***][***flags***]**

89052 Write the addressed lines. The behavior is unspecified if the number of columns on the display is
89053 less than the number of columns required to write any single character in the lines being written.

89054 Non-printable characters, except for the <tab>, shall be written as implementation-defined
89055 multi-character sequences.

89056 If the **#** flag is specified or the **number** edit option is set, each line shall be preceded by its line
89057 number in the following format:

89058 "%6dΔΔ", *<line number>*

89059 If the **l** flag is specified or the **list** edit option is set:

1. The characters listed in XBD Table 5-1 (on page 121) shall be written as the corresponding escape sequence.
2. Non-printable characters not in XBD Table 5-1 (on page 121) shall be written as one three-digit octal number (with a preceding <backslash>) for each byte in the character (most significant byte first).
3. The end of each line shall be marked with a '$', and literal '$' characters within the line shall be written with a preceding <backslash>.

Long lines shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output terminal, considering the number of columns of the terminal.

If a line is folded, and the **l** flag is not specified and the **list** edit option is not set, it is unspecified whether a multi-column character at the folding position is separated; it shall not be discarded.

Current line: Set to the last written line.

Current column: Unchanged if the current line is unchanged; otherwise, set to non-<blank>.

Put

Synopsis: **[***laddr***]** pu**[**t**][***buffer***]**

Append text from the specified buffer (by default, the unnamed buffer) to the specified line; line zero specifies that the text shall be placed at the beginning of the edit buffer. Each portion of a line in the buffer shall become a new line in the edit buffer, regardless of the mode of the buffer.

Current line: Set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Quit

Synopsis: q**[**uit**][**!**]**

If no '!' is appended to the command name:

1. If the edit buffer has been modified since the last complete write, it shall be an error.
2. If there are filenames in the argument list after the filename currently referenced, and the last command was not a **quit**, **wq**, **xit**, or **ZZ** (see Exit, on page 3410) command, it shall be an error.

Otherwise, terminate the editing session.

Read

Synopsis: **[***laddr***]** r**[**ead**][**!**][***file***]**

If '!' is not the first non-<blank> to follow the command name, a copy of the specified file shall be appended into the edit buffer after the specified line; line zero specifies that the copy shall be placed at the beginning of the edit buffer. The number of lines and bytes read shall be written. If no *file* is named, the current pathname shall be the default. If there is no current pathname, then *file* shall become the current pathname. If there is no current pathname or *file* operand, it shall be an error. Specifying a *file* that is not of type regular shall have unspecified results.

Otherwise, if *file* is preceded by '!', the rest of the line after the '!' shall have '%', '#', and '!' characters expanded as described in Command Line Parsing in ex (on page 2705).

The *ex* utility shall then pass two arguments to the program named by the shell edit option; the

first shall be **−c** and the second shall be the expanded arguments to the **read** command as a single argument. The standard input of the program shall be set to the standard input of the *ex* program when it was invoked. The standard error and standard output of the program shall be appended into the edit buffer after the specified line.

Each line in the copied file or program output (as delimited by <newline> characters or the end of the file or output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline> characters.

The special meaning of the `'!'` following the **read** command can be overridden by escaping it with a <backslash> character.

Current line: If no lines are added to the edit buffer, unchanged. Otherwise, if in open or visual mode, set to the first line entered into the edit buffer. Otherwise, set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Recover

Synopsis: `rec[over][!]` *file*

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.

If no *file* operand is specified, then the current pathname shall be used. If there is no current pathname or *file* operand, it shall be an error.

If no recovery information has previously been saved about *file*, the **recover** command shall behave identically to the **edit** command, and an informational message to this effect shall be written.

Otherwise, set the current pathname to *file*, and replace the current contents of the edit buffer with the recovered contents of *file*. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. The editor shall behave as if the contents of the edit buffer have already been modified.

Current file: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Rewind

Synopsis: `rew[ind][!]`

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If the argument list is empty, it shall be an error.

The current argument list reference and the current pathname shall be set to the first filename in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Set

Synopsis: `se[t][option[=[value]] ...][nooption ...][option? ...][all]`

When no arguments are specified, write the value of the **term** edit option and those options whose values have been changed from the default settings; when the argument *all* is specified, write all of the option values.

Giving an option name followed by the character `'?'` shall cause the current value of that option to be written. The `'?'` can be separated from the option name by zero or more <blank> characters. The `'?'` shall be necessary only for Boolean valued options. Boolean options can be given values by the form **set** *option* to turn them on or **set no***option* to turn them off; string and numeric options can be assigned by the form **set** *option*=*value*. Any <blank> characters in strings can be included as is by preceding each <blank> with an escaping <backslash>. More than one option can be set or listed by a single set command by specifying multiple arguments, each separated from the next by one or more <blank> characters.

See Edit Options in ex (on page 2735) for details about specific options.

Current line: Unchanged.

Current column: Unchanged.

Shell

Synopsis: `sh[ell]`

Invoke the program named in the **shell** edit option with the single argument **–i** (interactive mode). Editing shall be resumed when the program exits.

Current line: Unchanged.

Current column: Unchanged.

Source

Synopsis: `so[urce] file`

Read and execute *ex* commands from *file*. Lines in the file that are blank lines shall be ignored.

Current line: As specified for the individual *ex* commands.

Current column: As specified for the individual *ex* commands.

Substitute

Synopsis:
```
[2addr] s[ubstitute][/pattern/repl/[options][count][flags]]
[2addr] &[options][count][flags]]
[2addr] ~[options][count][flags]]
```

Replace the first instance of the pattern *pattern* by the string *repl* on each specified line. (See Regular Expressions in ex (on page 2734) and Replacement Strings in ex (on page 2735).) Any non-alphabetic, non-<blank> delimiter other than <backslash>, `'|'`, <newline>, or double-quote can be used instead of `'/'`. <backslash> characters can be used to escape delimiters, <backslash> characters, and other special characters.

The trailing delimiter can be omitted from *pattern* or from *repl* at the end of the command line. If both *pattern* and *repl* are not specified or are empty (for example, `"//"`), the last **s** command shall be repeated. If only *pattern* is not specified or is empty, the last regular expression used in the editor shall be used as the pattern. If only *repl* is not specified or is empty, the pattern shall be replaced by nothing. If the entire replacement pattern is `'%'`, the last replacement pattern to an **s** command shall be used.

Entering a <carriage-return> in *repl* (which requires an escaping <backslash> in *ex* mode and an escaping <control>-V in open or *vi* mode) shall split the line at that point, creating a new line in the edit buffer. The <carriage-return> shall be discarded.

If *options* includes the letter `'g'` (**global**), all non-overlapping instances of the pattern in the line shall be replaced.

If *options* includes the letter `'c'` (**confirm**), then before each substitution the line shall be written; the written line shall reflect all previous substitutions. On the following line, <space> characters shall be written beneath the characters from the line that are before the *pattern* to be replaced, and `'^'` characters written beneath the characters included in the *pattern* to be replaced. The *ex* utility shall then wait for a response from the user. An affirmative response shall cause the substitution to be done, while any other input shall not make the substitution. An affirmative response shall consist of a line with the affirmative response (as defined by the current locale) at the beginning of the line. This line shall be subject to editing in the same way as the *ex* command line.

If interrupted (see the ASYNCHRONOUS EVENTS section), any modifications confirmed by the user shall be preserved in the edit buffer after the interrupt.

If the remembered search direction is not set, the **s** command shall set it to forward.

In the second Synopsis, the **&** command shall repeat the previous substitution, as if the **&** command were replaced by:

`s/`*pattern*`/`*repl*`/`

where *pattern* and *repl* are as specified in the previous **s**, **&**, or **~** command.

In the third Synopsis, the **~** command shall repeat the previous substitution, as if the `'~'` were replaced by:

`s/`*pattern*`/`*repl*`/`

where *pattern* shall be the last regular expression specified to the editor, and *repl* shall be from the previous substitution (including **&** and **~**) command.

These commands shall be affected by the *LC_MESSAGES* environment variable.

Current line: Set to the last line in which a substitution occurred, or, unchanged if no substitution occurred.

Current column: Set to non-<blank>.

89215 **Suspend**

89216 *Synopsis*: `su[spend][!]`
89217 `st[op][!]`

89218 Allow control to return to the invoking process; *ex* shall suspend itself as if it had received the
89219 SIGTSTP signal. The suspension shall occur only if job control is enabled in the invoking shell
89220 (see the description of *set* **–m**).

89221 These commands shall be affected by the **autowrite** and **writeany** edit options.

89222 The current **susp** character (see *stty*) shall be equivalent to the **suspend** command.

89223 **Tag**

89224 *Synopsis*: `ta[g][!]` *tagstring*

89225 The results are unspecified if the format of a tags file is not as specified by the *ctags* utility (see
89226 *ctags*) description.

89227 The **tag** command shall search for *tagstring* in the tag files referred to by the **tag** edit option, in
89228 the order they are specified, until a reference to *tagstring* is found. Files shall be searched from
89229 beginning to end. If no reference is found, it shall be an error and an error message to this effect
89230 shall be written. If the reference is not found, or if an error occurs while processing a file referred
89231 to in the **tag** edit option, it shall be an error, and an error message shall be written at the first
89232 occurrence of such an error.

89233 Otherwise, if the tags file contained a pattern, the pattern shall be treated as a regular expression
89234 used in the editor; for example, for the purposes of the **s** command.

89235 If the *tagstring* is in a file with a different name than the current pathname, set the current
89236 pathname to the name of that file, and replace the contents of the edit buffer with the contents of
89237 that file. In this case, if no `'!'` is appended to the command name, and the edit buffer has been
89238 modified since the last complete write, it shall be an error, unless the file is successfully written
89239 as specified by the **autowrite** option.

89240 This command shall be affected by the **autowrite**, **tag**, **taglength**, and **writeany** edit options.

89241 *Current line*: If the tags file contained a line number, set to that line number. If the line number is
89242 larger than the last line in the edit buffer, an error message shall be written and the current line
89243 shall be set as specified for the **edit** command.

89244 If the tags file contained a pattern, set to the first occurrence of the pattern in the file. If no
89245 matching pattern is found, an error message shall be written and the current line shall be set as
89246 specified for the **edit** command.

89247 *Current column*: If the tags file contained a line-number reference and that line-number was not
89248 larger than the last line in the edit buffer, or if the tags file contained a pattern and that pattern
89249 was found, set to non-<blank>. Otherwise, set as specified for the **edit** command.

89250 **Unabbreviate**

89251 *Synopsis*: `una[bbrev]` *lhs*

89252 If *lhs* is not an entry in the current list of abbreviations (see Abbreviate, on page 2713), it shall be
89253 an error. Otherwise, delete *lhs* from the list of abbreviations.

89254 *Current line*: Unchanged.

89255 *Current column*: Unchanged.

89256 **Undo**

89257 *Synopsis*: `u[ndo]`

89258 Reverse the changes made by the last command that modified the contents of the edit buffer,
89259 including **undo**. For this purpose, the **global**, **v**, **open**, and **visual** commands, and commands
89260 resulting from buffer executions and mapped character expansions, are considered single
89261 commands.

89262 If no action that can be undone preceded the **undo** command, it shall be an error.

89263 If the **undo** command restores lines that were marked, the mark shall also be restored unless it
89264 was reset subsequent to the deletion of the lines.

89265 *Current line*:

89266 1. If lines are added or changed in the file, set to the first line added or changed.
89267 2. Set to the line before the first line deleted, if it exists.
89268 3. Set to 1 if the edit buffer is not empty.
89269 4. Set to zero.

89270 *Current column*: Set to non-<blank>.

89271 **Unmap**

89272 *Synopsis*: `unm[ap][!]` *lhs*

89273 If `'!'` is appended to the command name, and if *lhs* is not an entry in the list of text input mode
89274 map definitions, it shall be an error. Otherwise, delete *lhs* from the list of text input mode map
89275 definitions.

89276 If no `'!'` is appended to the command name, and if *lhs* is not an entry in the list of command
89277 mode map definitions, it shall be an error. Otherwise, delete *lhs* from the list of command mode
89278 map definitions.

89279 *Current line*: Unchanged.

89280 *Current column*: Unchanged.

89281 **Version**

89282 *Synopsis*: `ve[rsion]`

89283 Write a message containing version information for the editor. The format of the message is
89284 unspecified.

89285 *Current line*: Unchanged.

89286 *Current column*: Unchanged.

89287 **Visual**

89288 *Synopsis*: `[`*`1addr`*`] vi[sual][`*`type`*`][`*`count`*`][`*`flags`*`]`

89289 If *ex* is currently in open or visual mode, the Synopsis and behavior of the visual command shall
89290 be the same as the **edit** command, as specified by Edit (on page 2715).

89291 Otherwise, this command need not be supported on block-mode terminals or terminals with
89292 insufficient capabilities. If standard input, standard output, or standard error are not terminal
89293 devices, the results are unspecified.

89294 If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in
89295 window, on page 2742). If the `'^'` type character was also specified, the **window** edit option
89296 shall be set before being used by the type character.

89297 Enter visual mode. If *type* is not specified, it shall be as if a *type* of `'+'` was specified. The *type*
89298 shall cause the following effects:

89299 + Place the beginning of the specified line at the top of the display.

89300 − Place the end of the specified line at the bottom of the display.

89301 . Place the beginning of the specified line in the middle of the display.

89302 ^ If the specified line is less than or equal to the value of the **window** edit option, set the line
89303 to 1; otherwise, decrement the line by the value of the **window** edit option minus 1. Place
89304 the beginning of this line as close to the bottom of the displayed lines as possible, while still
89305 displaying the value of the **window** edit option number of lines.

89306 *Current line*: Set to the specified line.

89307 *Current column*: Set to non-<blank>.

89308 **Write**

89309 *Synopsis*: `[`*`2addr`*`] w[rite][!][>>][`*`file`*`]`
89310 `[`*`2addr`*`] w[rite][!][`*`file`*`]`
89311 `[`*`2addr`*`] wq[!][>>][`*`file`*`]`

89312 If no lines are specified, the lines shall default to the entire file.

89313 The command **wq** shall be equivalent to a **write** command followed by a **quit** command; **wq!**
89314 shall be equivalent to **write!** followed by **quit**. In both cases, if the **write** command fails, the
89315 **quit** shall not be attempted.

89316 If the command name is not followed by one or more <blank> characters, or *file* is not preceded
89317 by a `'!'` character, the **write** shall be to a file.

89318 1. If the **>>** argument is specified, and the file already exists, the lines shall be appended to
89319 the file instead of replacing its contents. If the **>>** argument is specified, and the file does
89320 not already exist, it is unspecified whether the write shall proceed as if the **>>** argument

had not been specified or if the write shall fail.

2. If the **readonly** edit option is set (see readonly, on page 2739), the **write** shall fail.
3. If *file* is specified, and is not the current pathname, and the file exists, the **write** shall fail.
4. If *file* is not specified, the current pathname shall be used. If there is no current pathname, the **write** command shall fail.
5. If the current pathname is used, and the current pathname has been changed by the **file** or **read** commands, and the file exists, the **write** shall fail. If the **write** is successful, subsequent **write**s shall not fail for this reason (unless the current pathname is changed again).
6. If the whole edit buffer is not being written, and the file to be written exists, the **write** shall fail.

For rules 1., 2., 3., and 5., the **write** can be forced by appending the character `'!'` to the command name.

For rules 2., 3., and 5., the **write** can be forced by setting the **writeany** edit option.

Additional, implementation-defined tests may cause the **write** to fail.

If the edit buffer is empty, a file without any contents shall be written.

An informational message shall be written noting the number of lines and bytes written.

Otherwise, if the command is followed by one or more <blank> characters, and the file is preceded by `'!'`, the rest of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as described in Command Line Parsing in ex (on page 2705).

The *ex* utility shall then pass two arguments to the program named by the **shell** edit option; the first shall be **−c** and the second shall be the expanded arguments to the **write** command as a single argument. The specified lines shall be written to the standard input of the command. The standard error and standard output of the program, if any, shall be written as described for the **print** command. If the last character in that output is not a <newline>, a <newline> shall be written at the end of the output.

The special meaning of the `'!'` following the **write** command can be overridden by escaping it with a <backslash> character.

Current line: Unchanged.

Current column: Unchanged.

Write and Exit

Synopsis: **[***2addr***]** x**[**it**][**!**][***file***]**

If the edit buffer has not been modified since the last complete **write**, **xit** shall be equivalent to the **quit** command, or if a `'!'` is appended to the command name, to **quit!**.

Otherwise, **xit** shall be equivalent to the **wq** command, or if a `'!'` is appended to the command name, to **wq!**.

Current line: Unchanged.

Current column: Unchanged.

89359 **Yank**

89360 *Synopsis*: `[`*2addr*`] ya[nk][`*buffer*`][`*count*`]`

89361 Copy the specified lines to the specified buffer (by default, the unnamed buffer), which shall
89362 become a line-mode buffer.

89363 *Current line*: Unchanged.

89364 *Current column*: Unchanged.

89365 **Adjust Window**

89366 *Synopsis*: `[`*1addr*`] z[!][`*type ...*`][`*count*`][`*flags*`]`

89367 If no line is specified, the current line shall be the default; if *type* is omitted as well, the current
89368 line value shall first be incremented by 1. If incrementing the current line would cause it to be
89369 greater than the last line in the edit buffer, it shall be an error.

89370 If there are <blank> characters between the *type* argument and the preceding **z** command name
89371 or optional `'!'` character, it shall be an error.

89372 If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in
89373 window, on page 2742). If *count* is omitted, it shall default to 2 times the value of the **scroll** edit
89374 option, or if **!** was specified, the number of lines in the display minus 1.

89375 If *type* is omitted, then *count* lines starting with the specified line shall be written. Otherwise,
89376 *count* lines starting with the line specified by the *type* argument shall be written.

89377 The *type* argument shall change the lines to be written. The possible values of *type* are as follows:

89378 – The specified line shall be decremented by the following value:

89379 `(((number of '−' characters) x` *count*`) −1)`

89380 If the calculation would result in a number less than 1, it shall be an error. Write lines from
89381 the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit
89382 buffer has been written.

89383 + The specified line shall be incremented by the following value:

89384 `(((number of '+' characters) −1) x` *count*`) +1`

89385 If the calculation would result in a number greater than the last line in the edit buffer, it
89386 shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count*
89387 lines or the last line in the edit buffer has been written.

89388 =, . If more than a single `'.'` or `'='` is specified, it shall be an error. The following steps shall
89389 be taken:

89390 1. If *count* is zero, nothing shall be written.

89391 2. Write as many of the *N* lines before the current line in the edit buffer as exist. If *count*
89392 or `'!'` was specified, *N* shall be:

89393 `(`*count* `−1) /2`

89394 Otherwise, *N* shall be:

89395 `(`*count* `−3) /2`

89396 If *N* is a number less than 3, no lines shall be written.

89397 3. If `'='` was specified as the type character, write a line consisting of the smaller of the
89398 number of columns in the display divided by two, or 40 `'−'` characters.

89399 4. Write the current line.

89400 5. Repeat step 3.

89401 6. Write as many of the *N* lines after the current line in the edit buffer as exist. *N* shall
89402 be defined as in step 2. If *N* is a number less than 3, no lines shall be written. If *count*
89403 is less than 3, no lines shall be written.

89404 `^` The specified line shall be decremented by the following value:

89405 `(((number of '^' characters) +1) x` *count*`) −1`

89406 If the calculation would result in a number less than 1, it shall be an error. Write lines from
89407 the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit
89408 buffer has been written.

89409 *Current line*: Set to the last line written, unless the type is **=**, in which case, set to the specified
89410 line.

89411 *Current column*: Set to non-<blank>.

89412 **Escape**

89413 *Synopsis*: `!` *command*
89414 **[***addr***]** `!` *command*

89415 The contents of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as
89416 described in Command Line Parsing in ex (on page 2705). If the expansion causes the text of the
89417 line to change, it shall be redisplayed, preceded by a single `'!'` character.

89418 The *ex* utility shall execute the program named by the **shell** edit option. It shall pass two
89419 arguments to the program; the first shall be **−c**, and the second shall be the expanded arguments
89420 to the **!** command as a single argument.

89421 If no lines are specified, the standard input, standard output, and standard error of the program
89422 shall be set to the standard input, standard output, and standard error of the *ex* program when it
89423 was invoked. In addition, a warning message shall be written if the edit buffer has been
89424 modified since the last complete write, and the **warn** edit option is set.

89425 If lines are specified, they shall be passed to the program as standard input, and the standard
89426 output and standard error of the program shall replace those lines in the edit buffer. Each line in
89427 the program output (as delimited by <newline> characters or the end of the output if it is not
89428 immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any
89429 occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single
89430 <newline> characters. The specified lines shall be copied into the unnamed buffer before they
89431 are replaced, and the unnamed buffer shall become a line-mode buffer.

89432 If in *ex* mode, a single `'!'` character shall be written when the program completes.

89433 This command shall be affected by the **shell** and **warn** edit options. If no lines are specified, this
89434 command shall be affected by the **autowrite** and **writeany** edit options. If lines are specified, this
89435 command shall be affected by the **autoprint** edit option.

Current line:

1. If no lines are specified, unchanged.
2. Otherwise, set to the last line read in, if any lines are read in.
3. Otherwise, set to the line before the first line of the lines specified, if that line exists.
4. Otherwise, set to the first line of the edit buffer if the edit buffer is not empty.
5. Otherwise, set to zero.

Current column: If no lines are specified, unchanged. Otherwise, set to non-<blank>.

Shift Left

Synopsis: **[***2addr***]** **<[<** **...][***count***][***flags***]**

Shift the specified lines to the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. Only leading <blank> characters shall be deleted or changed into other <blank> characters in shifting; other characters shall not be affected.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

Shift Right

Synopsis: **[***2addr***]** **>[>** **...][***count***][***flags***]**

Shift the specified lines away from the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. The shift shall be accomplished by adding <blank> characters as a prefix to the line or changing leading <blank> characters into other <blank> characters. Empty lines shall not be changed.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

<control>-D

Synopsis: `<control>-D`

Write the next *n* lines, where *n* is the minimum of the values of the **scroll** edit option and the number of lines after the current line in the edit buffer. If the current line is the last line of the edit buffer it shall be an error.

Current line: Set to the last line written.

Current column: Set to non-<blank>.

89473 **Write Line Number**

89474 *Synopsis*: **[***laddr***]** = **[***flags***]**

89475 If *line* is not specified, it shall default to the last line in the edit buffer. Write the line number of
89476 the specified line.

89477 *Current line*: Unchanged.

89478 *Current column*: Unchanged.

89479 **Execute**

89480 *Synopsis*: **[***2addr***]** @ *buffer*
89481 **[***2addr***]** * *buffer*

89482 If no buffer is specified or is specified as '@' or '*', the last buffer executed shall be used. If no
89483 previous buffer has been executed, it shall be an error.

89484 For each line specified by the addresses, set the current line ('.') to the specified line, and
89485 execute the contents of the named *buffer* (as they were at the time the @ command was executed)
89486 as *ex* commands. For each line of a line-mode buffer, and all but the last line of a character-mode
89487 buffer, the *ex* command parser shall behave as if the line was terminated by a <newline>.

89488 If an error occurs during this process, or a line specified by the addresses does not exist when
89489 the current line would be set to it, or more than a single line was specified by the addresses, and
89490 the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error
89491 message shall be written, and no more commands resulting from the execution of this command
89492 shall be processed.

89493 *Current line*: As specified for the individual *ex* commands.

89494 *Current column*: As specified for the individual *ex* commands.

89495 **Regular Expressions in ex**

89496 The *ex* utility shall support regular expressions that are a superset of the basic regular
89497 expressions described in XBD Section 9.3 (on page 183). A null regular expression ("//") shall
89498 be equivalent to the last regular expression encountered.

89499 Regular expressions can be used in addresses to specify lines and, in some commands (for
89500 example, the **substitute** command), to specify portions of a line to be substituted.

89501 The following constructs can be used to enhance the basic regular expressions:

89502 \< Match the beginning of a *word*. (See the definition of *word* at the beginning of Command
89503 Descriptions in ex (on page 2710).)

89504 \> Match the end of a *word*.

89505 ~ Match the replacement part of the last **substitute** command. The <tilde> ('~') character can
89506 be escaped in a regular expression to become a normal character with no special meaning.
89507 The <backslash> shall be discarded.

89508 When the editor option **magic** is not set, the only characters with special meanings shall be '^'
89509 at the beginning of a pattern, '$' at the end of a pattern, and <backslash>. The characters '.',
89510 '*', '[', and '~' shall be treated as ordinary characters unless preceded by a <backslash>;
89511 when preceded by a <backslash> they shall regain their special meaning, or in the case of
89512 <backslash>, be handled as a single <backslash>. <backslash> characters used to escape other
89513 characters shall be discarded.

89514 **Replacement Strings in ex**

89515 The character '&' ('\&' if the editor option **magic** is not set) in the replacement string shall
89516 stand for the text matched by the pattern to be replaced. The character '~' ('\~' if **magic** is not
89517 set) shall be replaced by the replacement part of the previous **substitute** command. The
89518 sequence '\n', where *n* is an integer, shall be replaced by the text matched by the
89519 corresponding back-reference expression. If the corresponding back-reference expression does
89520 not match, then the characters '\n' shall be replaced by the empty string.

89521 The strings '\l', '\u', '\L', and '\U' can be used to modify the case of elements in the
89522 replacement string (using the '\&' or "\"digit) notation. The string '\l' ('\u') shall cause
89523 the character that follows to be converted to lowercase (uppercase). The string '\L' ('\U') shall
89524 cause all characters subsequent to it to be converted to lowercase (uppercase) as they are
89525 inserted by the substitution until the string '\e' or '\E', or the end of the replacement string,
89526 is encountered.

89527 Otherwise, any character following a <backslash> shall be treated as that literal character, and
89528 the escaping <backslash> shall be discarded.

89529 An example of case conversion with the **s** command is as follows:

```
89530 :p
89531 The cat sat on the mat.
89532 :s/\<.at\>/\u&/gp
89533 The Cat Sat on the Mat.
89534 :s/S\(.*\)M/S\U\1\eM/p
89535 The Cat SAT ON THE Mat.
```

89536 **Edit Options in ex**

89537 The *ex* utility has a number of options that modify its behavior. These options have default
89538 settings, which can be changed using the **set** command.

89539 Options are Boolean unless otherwise specified.

89540 **autoindent, ai**

89541 [Default *unset*]

89542 If **autoindent** is set, each line in input mode shall be indented (using first as many <tab>
89543 characters as possible, as determined by the editor option **tabstop**, and then using <space>
89544 characters) to align with another line, as follows:

89545 1. If in open or visual mode and the text input is part of a line-oriented command (see the
89546 EXTENDED DESCRIPTION in *vi*), align to the first column.

89547 2. Otherwise, if in open or visual mode, indentation for each line shall be set as follows:

89548 a. If a line was previously inserted as part of this command, it shall be set to the
89549 indentation of the last inserted line by default, or as otherwise specified for the
89550 <control>-D character in Input Mode Commands in vi (on page 3410).

89551 b. Otherwise, it shall be set to the indentation of the previous current line, if any;
89552 otherwise, to the first column.

89553 3. For the *ex* **a**, **i**, and **c** commands, indentation for each line shall be set as follows:

a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the *eof* character in Scroll (on page 2709).

b. Otherwise, if the command is the *ex* **a** command, it shall be set to the line appended after, if any; otherwise to the first column.

c. Otherwise, if the command is the *ex* **i** command, it shall be set to the line inserted before, if any; otherwise to the first column.

d. Otherwise, if the command is the *ex* **c** command, it shall be set to the indentation of the line replaced.

autoprint, ap

[Default *set*]

If **autoprint** is set, the current line shall be written after each *ex* command that modifies the contents of the current edit buffer, and after each **tag** command for which the tag search pattern was found or tag line number was valid, unless:

1. The command was executed while in open or visual mode.
2. The command was executed as part of a **global** or **v** command or **@** buffer execution.
3. The command was the form of the **read** command that reads a file into the edit buffer.
4. The command was the **append**, **change**, or **insert** command.
5. The command was not terminated by a <newline>.
6. The current line shall be written by a flag specified to the command; for example, **delete #** shall write the current line as specified for the flag modifier to the **delete** command, and not as specified by the **autoprint** edit option.

autowrite, aw

[Default *unset*]

If **autowrite** is set, and the edit buffer has been modified since it was last completely written to any file, the contents of the edit buffer shall be written as if the *ex* **write** command had been specified without arguments, before each command affected by the **autowrite** edit option is executed. Appending the character `'!'` to the command name of any of the *ex* commands except `'!'` shall prevent the write. If the write fails, it shall be an error and the command shall not be executed.

beautify, bf

XSI [Default *unset*]

If **beautify** is set, all non-printable characters, other than <tab>, <newline>, and <form-feed> characters, shall be discarded from text read in from files.

89588 **directory, dir**

89589 [Default *implementation-defined*]

89590 The value of this option specifies the directory in which the editor buffer is to be placed. If this
89591 directory is not writable by the user, the editor shall quit.

89592 **edcompatible, ed**

89593 [Default *unset*]

89594 Causes the presence of **g** and **c** suffixes on substitute commands to be remembered, and toggled
89595 by repeating the suffixes.

89596 **errorbells, eb**

89597 [Default *unset*]

89598 If the editor is in *ex* mode, and the terminal does not support a standout mode (such as inverse
89599 video), and **errorbells** is set, error messages shall be preceded by alerting the terminal.

89600 **exrc**

89601 [Default *unset*]

89602 If **exrc** is set, *ex* shall access any **.exrc** file in the current directory, as described in Initialization in
89603 ex and vi (on page 2701). If **exrc** is not set, *ex* shall ignore any **.exrc** file in the current directory
89604 during initialization, unless the current directory is that named by the *HOME* environment
89605 variable.

89606 **ignorecase, ic**

89607 [Default *unset*]

89608 If **ignorecase** is set, characters that have uppercase and lowercase representations shall have
89609 those representations considered as equivalent for purposes of regular expression comparison.

89610 The **ignorecase** edit option shall affect all remembered regular expressions; for example,
89611 unsetting the **ignorecase** edit option shall cause a subsequent *vi* **n** command to search for the
89612 last basic regular expression in a case-sensitive fashion.

89613 **list**

89614 [Default *unset*]

89615 If **list** is set, edit buffer lines written while in *ex* command mode shall be written as specified for
89616 the **print** command with the **l** flag specified. In open or visual mode, each edit buffer line shall
89617 be displayed as specified for the *ex* **print** command with the **l** flag specified. In open or visual
89618 text input mode, when the cursor does not rest on any character in the line, it shall rest on the
89619 `'$'` marking the end of the line.

89620 **magic**

89621 [Default *set*]

89622 If **magic** is set, modify the interpretation of characters in regular expressions and substitution
89623 replacement strings (see Regular Expressions in ex (on page 2734) and Replacement Strings in
89624 ex, on page 2735).

89625 **mesg**

89626 [Default *set*]

89627 If **mesg** is set, the permission for others to use the **write** or **talk** commands to write to the
89628 terminal shall be turned on while in open or visual mode. The shell-level command *mesg* **n** shall
89629 take precedence over any setting of the *ex* **mesg** option; that is, if **mesg y** was issued before the
89630 editor started (or in a shell escape), such as:

89631 `:!mesg y`

89632 the **mesg** option in *ex* shall suppress incoming messages, but the **mesg** option shall not enable
89633 incoming messages if **mesg n** was issued.

89634 **number, nu**

89635 [Default *unset*]

89636 If **number** is set, edit buffer lines written while in *ex* command mode shall be written with line
89637 numbers, in the format specified by the **print** command with the **#** flag specified. In *ex* text input
89638 mode, each line shall be preceded by the line number it will have in the file.

89639 In open or visual mode, each edit buffer line shall be displayed with a preceding line number, in
89640 the format specified by the *ex* **print** command with the **#** flag specified. This line number shall
89641 not be considered part of the line for the purposes of evaluating the current column; that is,
89642 column position 1 shall be the first column position after the format specified by the **print**
89643 command.

89644 **paragraphs, para**

89645 [Default in the POSIX locale `IPLPPPQPP LIpplpipbp`]

89646 The **paragraphs** edit option shall define additional paragraph boundaries for the open and
89647 visual mode commands. The **paragraphs** edit option can be set to a character string consisting of
89648 zero or more character pairs. It shall be an error to set it to an odd number of characters.

89649 **prompt**

89650 [Default *set*]

89651 If **prompt** is set, *ex* command mode input shall be prompted for with a <colon> (`':'`); when
89652 unset, no prompt shall be written.

89653 **readonly**

89654 [Default *see text*]

89655 If the **readonly** edit option is set, read-only mode shall be enabled (see Write, on page 2729). The
89656 **readonly** edit option shall be initialized to set if either of the following conditions are true:

89657 The command-line option –R was specified.

89658 Performing actions equivalent to the *access*( ) function called with the following arguments
89659 indicates that the file lacks write permission:

89660 1. The current pathname is used as the *path* argument.

89661 2. The constant **W_OK** is used as the *amode* argument.

89662 The **readonly** edit option may be initialized to set for other, implementation-defined reasons.
89663 The **readonly** edit option shall not be initialized to unset based on any special privileges of the
89664 user or process. The **readonly** edit option shall be reinitialized each time that the contents of the
89665 edit buffer are replaced (for example, by an **edit** or **next** command) unless the user has explicitly
89666 set it, in which case it shall remain set until the user explicitly unsets it. Once unset, it shall again
89667 be reinitialized each time that the contents of the edit buffer are replaced.

89668 **redraw**

89669 [Default *unset*]

89670 The editor simulates an intelligent terminal on a dumb terminal. (Since this is likely to require a
89671 large amount of output to the terminal, it is useful only at high transmission speeds.)

89672 **remap**

89673 [Default *set*]

89674 If **remap** is set, map translation shall allow for maps defined in terms of other maps; translation
89675 shall continue until a final product is obtained. If unset, only a one-step translation shall be
89676 done.

89677 **report**

89678 [Default 5]

89679 The value of this **report** edit option specifies what number of lines being added, copied, deleted,
89680 or modified in the edit buffer will cause an informational message to be written to the user. The
89681 following conditions shall cause an informational message. The message shall contain the
89682 number of lines added, copied, deleted, or modified, but is otherwise unspecified.

89683 An *ex* or *vi* editor command, other than **open**, **undo**, or **visual**, that modifies at least the
89684 value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v**
89685 command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.

89686 An *ex* **yank** or *vi* **y** or **Y** command, that copies at least the value of the **report** edit option
89687 plus 1 number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi*
89688 buffer execution, shall cause an informational message to be written.

89689 An *ex* **global**, **v**, **open**, **undo**, or **visual** command or *ex* or *vi* buffer execution, that adds or
89690 deletes a total of at least the value of the **report** edit option number of lines, and which is
89691 not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an
89692 informational message to be written. (For example, if 3 lines were added and 8 lines
89693 deleted during an *ex* **visual** command, 5 would be the number compared against the

89694 **report** edit option after the command completed.)

89695 **scroll, scr**

89696 [Default (number of lines in the display –1)/2]

89697 The value of the **scroll** edit option shall determine the number of lines scrolled by the *ex*
89698 <control>-D and **z** commands. For the *vi* <control>-D and <control>-U commands, it shall be the
89699 initial number of lines to scroll when no previous <control>-D or <control>-U command has
89700 been executed.

89701 **sections**

89702 [Default in the POSIX locale `NHSHH HUnhsh`]

89703 The **sections** edit option shall define additional section boundaries for the open and visual mode
89704 commands. The **sections** edit option can be set to a character string consisting of zero or more
89705 character pairs; it shall be an error to set it to an odd number of characters.

89706 **shell, sh**

89707 [Default from the environment variable *SHELL*]

89708 The value of this option shall be a string. The default shall be taken from the *SHELL*
89709 environment variable. If the *SHELL* environment variable is null or empty, the *sh* (see *sh*) utility
89710 shall be the default.

89711 **shiftwidth, sw**

89712 [Default 8]

89713 The value of this option shall give the width in columns of an indentation level used during
89714 autoindentation and by the shift commands (**<** and **>**).

89715 **showmatch, sm**

89716 [Default *unset*]

89717 The functionality described for the **showmatch** edit option need not be supported on block-
89718 mode terminals or terminals with insufficient capabilities.

89719 If **showmatch** is set, in open or visual mode, when a `')'` or `'}'` is typed, if the matching `'('` or
89720 `'{'` is currently visible on the display, the matching `'('` or `'{'` shall be flagged moving the
89721 cursor to its location for an unspecified amount of time.

89722 **showmode**

89723 [Default *unset*]

89724 If **showmode** is set, in open or visual mode, the current mode that the editor is in shall be
89725 displayed on the last line of the display. Command mode and text input mode shall be
89726 differentiated; other unspecified modes and implementation-defined information may be
89727 displayed.

89728 **slowopen**

89729 [Default *unset*]

89730 If **slowopen** is set during open and visual text input modes, the editor shall not update portions
89731 of the display other than those display line columns that display the characters entered by the
89732 user (see Input Mode Commands in vi, on page 3410).

89733 **tabstop, ts**

89734 [Default 8]

89735 The value of this edit option shall specify the column boundary used by a <tab> in the display
89736 (see autoprint, ap (on page 2736) and Input Mode Commands in vi, on page 3410).

89737 **taglength, tl**

89738 [Default zero]

89739 The value of this edit option shall specify the maximum number of characters that are
89740 considered significant in the user-specified tag name and in the tag name from the tags file. If
89741 the value is zero, all characters in both tag names shall be significant.

89742 **tags**

89743 [Default *see text*]

89744 The value of this edit option shall be a string of <blank>-delimited pathnames of files used by
89745 the **tag** command. The default value is unspecified.

89746 **term**

89747 [Default from the environment variable *TERM*]

89748 The value of this edit option shall be a string. The default shall be taken from the *TERM* variable
89749 in the environment. If the *TERM* environment variable is empty or null, the default is
89750 unspecified. The editor shall use the value of this edit option to determine the type of the display
89751 device.

89752 The results are unspecified if the user changes the value of the term edit option after editor
89753 initialization.

89754 **terse**

89755 [Default *unset*]

89756 If **terse** is set, error messages may be less verbose. However, except for this caveat, error
89757 messages are unspecified. Furthermore, not all error messages need change for different settings
89758 of this option.

89759 **warn**

89760 [Default *set*]

89761 If **warn** is set, and the contents of the edit buffer have been modified since they were last
89762 completely written, the editor shall write a warning message before certain **!** commands (see
89763 Escape, on page 2732).

89764 **window**

89765 [Default *see text*]

89766 A value used in open and visual mode, by the <control>-B and <control>-F commands, and, in
89767 visual mode, to specify the number of lines displayed when the screen is repainted.

89768 If the −**w** command-line option is not specified, the default value shall be set to the value of the
89769 *LINES* environment variable. If the *LINES* environment variable is empty or null, the default
89770 shall be the number of lines in the display minus 1.

89771 Setting the **window** edit option to zero or to a value greater than the number of lines in the
89772 display minus 1 (either explicitly or based on the −**w** option or the *LINES* environment variable)
89773 shall cause the **window** edit option to be set to the number of lines in the display minus 1.

89774 The baud rate of the terminal line may change the default in an implementation-defined manner.

89775 **wrapmargin, wm**

89776 [Default 0]

89777 If the value of this edit option is zero, it shall have no effect.

89778 If not in the POSIX locale, the effect of this edit option is implementation-defined.

89779 Otherwise, it shall specify a number of columns from the ending margin of the terminal.

89780 During open and visual text input modes, for each character for which any part of the character
89781 is displayed in a column that is less than **wrapmargin** columns from the ending margin of the
89782 display line, the editor shall behave as follows:

89783 1. If the character triggering this event is a <blank>, it, and all immediately preceding
89784 <blank> characters on the current line entered during the execution of the current text
89785 input command, shall be discarded, and the editor shall behave as if the user had entered
89786 a single <newline> instead. In addition, if the next user-entered character is a <space>, it
89787 shall be discarded as well.

89788 2. Otherwise, if there are one or more <blank> characters on the current line immediately
89789 preceding the last group of inserted non-<blank> characters which was entered during
89790 the execution of the current text input command, the <blank> characters shall be replaced
89791 as if the user had entered a single <newline> instead.

89792 If the **autoindent** edit option is set, and the events described in 1. or 2. are performed, any
89793 <blank> characters at or after the cursor in the current line shall be discarded.

89794 The ending margin shall be determined by the system or overridden by the user, as described for
89795 *COLUMNS* in the ENVIRONMENT VARIABLES section and XBD Chapter 8 (on page 173).

wrapscan, ws

[Default *set*]

If **wrapscan** is set, searches (the *ex* **/** or **?** addresses, or open and visual mode **/**, **?**, **N**, and **n** commands) shall wrap around the beginning or end of the edit buffer; when unset, searches shall stop at the beginning or end of the edit buffer.

writeany, wa

[Default *unset*]

If **writeany** is set, some of the checks performed when executing the *ex* **write** commands shall be inhibited, as described in editor option **autowrite**.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, *ex* shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered, it shall be equivalent to a SIGHUP asynchronous event.

Otherwise, when an error is encountered, the editor shall behave as specified in Command Line Parsing in ex (on page 2705).

APPLICATION USAGE

If a SIGSEGV signal is received while *ex* is saving a file, the file might not be successfully saved.

The **next** command can accept more than one file, so usage such as:

```
next `ls [abc]*`
```

is valid; it would not be valid for the **edit** or **read** commands, for example, because they expect only one file and unspecified results occur.

EXAMPLES

None.

RATIONALE

The *ex*/*vi* specification is based on the historical practice found in the 4 BSD and System V implementations of *ex* and *vi*.

A *restricted editor* (both the historical *red* utility and modifications to *ex*) were considered and rejected for inclusion. Neither option provided the level of security that users might expect.

It is recognized that *ex* visual mode and related features would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing; thus, it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that an *ex* implementation should provide the full set of capabilities on all terminals capable of supporting them.

Options

The −**c** replacement for **+***command* was inspired by the −**e** option of *sed*. Historically, all such commands (see **edit** and **next** as well) were executed from the last line of the edit buffer. This meant, for example, that `"+/pattern"` would fail unless the **wrapscan** option was set. POSIX.1-2017 requires conformance to historical practice. The +*command* option is no longer specified by POSIX.1-2017 but may be present in some implementations. Historically, some implementations restricted the *ex* commands that could be listed as part of the command line arguments. For consistency, POSIX.1-2017 does not permit these restrictions.

In historical implementations of the editor, the −**R** option (and the **readonly** edit option) only prevented overwriting of files; appending to files was still permitted, mapping loosely into the *csh* **noclobber** variable. Some implementations, however, have not followed this semantic, and **readonly** does not permit appending either. POSIX.1-2017 follows the latter practice, believing that it is a more obvious and intuitive meaning of **readonly**.

The −**s** option suppresses all interactive user feedback and is useful for editing scripts in batch jobs. The list of specific effects is historical practice. The terminal type ``incapable of supporting open and visual modes'' has historically been named ``dumb''.

The −**t** option was required because the *ctags* utility appears in POSIX.1-2017 and the option is available in all historical implementations of *ex*.

Historically, the *ex* and *vi* utilities accepted a −**x** option, which did encryption based on the algorithm found in the historical *crypt* utility. The −**x** option for encryption, and the associated *crypt* utility, were omitted because the algorithm used was not specifiable and the export control laws of some nations make it difficult to export cryptographic technology. In addition, it did not historically provide the level of security that users might expect.

Standard Input

An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically an *ex* command.

There was no maximum line length in historical implementations of *ex*. Specifically, as it was parsed in chunks, the addresses had a different maximum length than the filenames. Further, the maximum line buffer size was declared as BUFSIZ, which was different lengths on different systems. This version selected the value of {LINE_MAX} to impose a reasonable restriction on portable usage of *ex* and to aid test suite writers in their development of realistic tests that exercise this limit.

Input Files

It was an explicit decision by the standard developers that a <newline> be added to any file lacking one. It was believed that this feature of *ex* and *vi* was relied on by users in order to make text files lacking a trailing <newline> more portable. It is recognized that this will require a user-specified option or extension for implementations that permit *ex* and *vi* to edit files of type other than text if such files are not otherwise identified by the system. It was agreed that the ability to edit files of arbitrary type can be useful, but it was not considered necessary to mandate that an *ex* or *vi* implementation be required to handle files other than text files.

The paragraph in the INPUT FILES section, ``By default, ...'', is intended to close a long-standing security problem in *ex* and *vi*; that of the ``modeline'' or ``modelines'' edit option. This feature allows any line in the first or last five lines of the file containing the strings `"ex:"` or `"vi:"` (and, apparently, `"ei:"` or `"vx:"`) to be a line containing editor commands, and *ex* interprets all the text up to the next `':'` or <newline> as a command. Consider the

consequences, for example, of an unsuspecting user using *ex* or *vi* as the editor when replying to a mail message in which a line such as:

```
ex:! rm -rf :
```

appeared in the signature lines. The standard developers believed strongly that an editor should not by default interpret any lines of a file. Vendors are strongly urged to delete this feature from their implementations of *ex* and *vi*.

Asynchronous Events

The intention of the phrase ``complete write'' is that the entire edit buffer be written to stable storage. The note regarding temporary files is intended for implementations that use temporary files to back edit buffers unnamed by the user.

Historically, SIGQUIT was ignored by *ex*, but was the equivalent of the **Q** command in visual mode; that is, it exited visual mode and entered *ex* mode. POSIX.1-2017 permits, but does not require, this behavior. Historically, SIGINT was often used by *vi* users to terminate text input mode (<control>-C is often easier to enter than <ESC>). Some implementations of *vi* alerted the terminal on this event, and some did not. POSIX.1-2017 requires that SIGINT behave identically to <ESC>, and that the terminal not be alerted.

Historically, suspending the *ex* editor during text input mode was similar to SIGINT, as completed lines were retained, but any partial line discarded, and the editor returned to command mode. POSIX.1-2017 is silent on this issue; implementations are encouraged to follow historical practice, where possible.

Historically, the *vi* editor did not treat SIGTSTP as an asynchronous event, and it was therefore impossible to suspend the editor in visual text input mode. There are two major reasons for this. The first is that SIGTSTP is a broadcast signal on UNIX systems, and the chain of events where the shell *exec*s an application that then *exec*s *vi* usually caused confusion for the terminal state if SIGTSTP was delivered to the process group in the default manner. The second was that most implementations of the UNIX *curses* package did not handle SIGTSTP safely, and the receipt of SIGTSTP at the wrong time would cause them to crash. POSIX.1-2017 is silent on this issue; implementations are encouraged to treat suspension as an asynchronous event if possible.

Historically, modifications to the edit buffer made before SIGINT interrupted an operation were retained; that is, anywhere from zero to all of the lines to be modified might have been modified by the time the SIGINT arrived. These changes were not discarded by the arrival of SIGINT. POSIX.1-2017 permits this behavior, noting that the **undo** command is required to be able to undo these partially completed commands.

The action taken for signals other than SIGINT, SIGCONT, SIGHUP, and SIGTERM is unspecified because some implementations attempt to save the edit buffer in a useful state when other signals are received.

Standard Error

For *ex*/*vi*, diagnostic messages are those messages reported as a result of a failed attempt to invoke *ex* or *vi*, such as invalid options or insufficient resources, or an abnormal termination condition. Diagnostic messages should not be confused with the error messages generated by inappropriate or illegal user commands.

89921 **Initialization in ex and vi**

89922 If an *ex* command (other than **cd**, **chdir**, or **source**) has a filename argument, one or both of the
89923 alternate and current pathnames will be set. Informally, they are set as follows:

89924 1. If the *ex* command is one that replaces the contents of the edit buffer, and it succeeds, the
89925 current pathname will be set to the filename argument (the first filename argument in the
89926 case of the **next** command) and the alternate pathname will be set to the previous current
89927 pathname, if there was one.

89928 2. In the case of the file read/write forms of the **read** and **write** commands, if there is no
89929 current pathname, the current pathname will be set to the filename argument.

89930 3. Otherwise, the alternate pathname will be set to the filename argument.

89931 For example, **:edit foo** and **:recover foo**, when successful, set the current pathname, and, if there
89932 was a previous current pathname, the alternate pathname. The commands **:write**, **!command**,
89933 and **:edit** set neither the current or alternate pathnames. If the **:edit foo** command were to fail for
89934 some reason, the alternate pathname would be set. The **read** and **write** commands set the
89935 alternate pathname to their *file* argument, unless the current pathname is not set, in which case
89936 they set the current pathname to their *file* arguments. The alternate pathname was not
89937 historically set by the **:source** command. POSIX.1-2017 requires conformance to historical
89938 practice. Implementations adding commands that take filenames as arguments are encouraged
89939 to set the alternate pathname as described here.

89940 Historically, *ex* and *vi* read the **.exrc** file in the *$HOME* directory twice, if the editor was executed
89941 in the *$HOME* directory. POSIX.1-2017 prohibits this behavior.

89942 Historically, the 4 BSD *ex* and *vi* read the *$HOME* and local **.exrc** files if they were owned by the
89943 real ID of the user, or the **sourceany** option was set, regardless of other considerations. This was
89944 a security problem because it is possible to put normal UNIX system commands inside a **.exrc**
89945 file. POSIX.1-2017 does not specify the **sourceany** option, and historical implementations are
89946 encouraged to delete it.

89947 The **.exrc** files must be owned by the real ID of the user, and not writable by anyone other than
89948 the owner. The appropriate privileges exception is intended to permit users to acquire special
89949 privileges, but continue to use the **.exrc** files in their home directories.

89950 System V Release 3.2 and later *vi* implementations added the option **[no]exrc**. The behavior is
89951 that local **.exrc** files are read-only if the **exrc** option is set. The default for the **exrc** option was off,
89952 so by default, local **.exrc** files were not read. The problem this was intended to solve was that
89953 System V permitted users to give away files, so there is no possible ownership or writeability
89954 test to ensure that the file is safe. This is still a security problem on systems where users can give
89955 away files, but there is nothing additional that POSIX.1-2017 can do. The implementation-
89956 defined exception is intended to permit groups to have local **.exrc** files that are shared by users,
89957 by creating pseudo-users to own the shared files.

89958 POSIX.1-2017 does not mention system-wide *ex* and *vi* start-up files. While they exist in several
89959 implementations of *ex* and *vi*, they are not present in any implementations considered historical
89960 practice by POSIX.1-2017. Implementations that have such files should use them only if they are
89961 owned by the real user ID or an appropriate user (for example, root on UNIX systems) and if
89962 they are not writable by any user other than their owner. System-wide start-up files should be
89963 read before the *EXINIT* variable, **$HOME/.exrc**, or local **.exrc** files are evaluated.

89964 Historically, any *ex* command could be entered in the *EXINIT* variable or the **.exrc** file, although
89965 ones requiring that the edit buffer already contain lines of text generally caused historical
89966 implementations of the editor to drop **core**. POSIX.1-2017 requires that any *ex* command be

permitted in the *EXINIT* variable and **.exrc** files, for simplicity of specification and consistency, although many of them will obviously fail under many circumstances.

The initialization of the contents of the edit buffer uses the phrase ``the effect shall be'' with regard to various *ex* commands. The intent of this phrase is that edit buffer contents loaded during the initialization phase not be lost; that is, loading the edit buffer should fail if the **.exrc** file read in the contents of a file and did not subsequently write the edit buffer. An additional intent of this phrase is to specify that the initial current line and column is set as specified for the individual *ex* commands.

Historically, the **−t** option behaved as if the tag search were a **+***command*; that is, it was executed from the last line of the file specified by the tag. This resulted in the search failing if the pattern was a forward search pattern and the **wrapscan** edit option was not set. POSIX.1-2017 does not permit this behavior, requiring that the search for the tag pattern be performed on the entire file, and, if not found, that the current line be set to a more reasonable location in the file.

Historically, the empty edit buffer presented for editing when a file was not specified by the user was unnamed. This is permitted by POSIX.1-2017; however, implementations are encouraged to provide users a temporary filename for this buffer because it permits them the use of *ex* commands that use the current pathname during temporary edit sessions.

Historically, the file specified using the **−t** option was not part of the current argument list. This practice is permitted by POSIX.1-2017; however, implementations are encouraged to include its name in the current argument list for consistency.

Historically, the **−c** command was generally not executed until a file that already exists was edited. POSIX.1-2017 requires conformance to this historical practice. Commands that could cause the **−c** command to be executed include the *ex* commands **edit**, **next**, **recover**, **rewind**, and **tag**, and the *vi* commands <control>-^ and <control>-]. Historically, reading a file into an edit buffer did not cause the **−c** command to be executed (even though it might set the current pathname) with the exception that it did cause the **−c** command to be executed if: the editor was in *ex* mode, the edit buffer had no current pathname, the edit buffer was empty, and no read commands had yet been attempted. For consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior.

Historically, the **−r** option was the same as a normal edit session if there was no recovery information available for the file. This allowed users to enter:

```
vi −r *.c
```

and recover whatever files were recoverable. In some implementations, recovery was attempted only on the first file named, and the file was not entered into the argument list; in others, recovery was attempted for each file named. In addition, some historical implementations ignored **−r** if **−t** was specified or did not support command line *file* arguments with the **−t** option. For consistency and simplicity of specification, POSIX.1-2017 disallows these special cases, and requires that recovery be attempted the first time each file is edited.

Historically, *vi* initialized the ` and ' marks, but *ex* did not. This meant that if the first command in *ex* mode was **visual** or if an *ex* command was executed first (for example, *vi* +10 *file*), *vi* was entered without the marks being initialized. Because the standard developers believed the marks to be generally useful, and for consistency and simplicity of specification, POSIX.1-2017 requires that they always be initialized if in open or visual mode, or if in *ex* mode and the edit buffer is not empty. Not initializing it in *ex* mode if the edit buffer is empty is historical practice; however, it has always been possible to set (and use) marks in empty edit buffers in open and visual mode edit sessions.

Addressing

Historically, *ex* and *vi* accepted the additional addressing forms `'\/'` and `'\?'`. They were equivalent to `"//"` and `"??"`, respectively. They are not required by POSIX.1-2017, mostly because nobody can remember whether they ever did anything different historically.

Historically, *ex* and *vi* permitted an address of zero for several commands, and permitted the **%** address in empty files for others. For consistency, POSIX.1-2017 requires support for the former in the few commands where it makes sense, and disallows it otherwise. In addition, because POSIX.1-2017 requires that **%** be logically equivalent to `"1,$"`, it is also supported where it makes sense and disallowed otherwise.

Historically, the **%** address could not be followed by further addresses. For consistency and simplicity of specification, POSIX.1-2017 requires that additional addresses be supported.

All of the following are valid *addresses*:

`+++` Three lines after the current line.

`/`*re*`/-` One line before the next occurrence of *re*.

`-2` Two lines before the current line.

`3 ---- 2` Line one (note intermediate negative address).

`1 2 3` Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the <semicolon> delimiter, permits users to create commands based on ordered patterns in the file. For example, the command **3;/foo/;+2print** will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address **3;** must be evaluated before being discarded because the search origin for the **/foo/** command depends on this.

Historically, values could be added to addresses by including them after one or more <blank> characters; for example, **3 - 5p** wrote the seventh line of the file, and **/foo/ 5** was the same as **/foo/+5**. However, only absolute values could be added; for example, **5 /foo/** was an error. POSIX.1-2017 requires conformance to historical practice. Address offsets are separately specified from addresses because they could historically be provided to visual mode search commands.

Historically, any missing addresses defaulted to the current line. This was true for leading and trailing <comma>-delimited addresses, and for trailing <semicolon>-delimited addresses. For consistency, POSIX.1-2017 requires it for leading <semicolon> addresses as well.

Historically, *ex* and *vi* accepted the `'^'` character as both an address and as a flag offset for commands. In both cases it was identical to the `'-'` character. POSIX.1-2017 does not require or prohibit this behavior.

Historically, the enhancements to basic regular expressions could be used in addressing; for example, `'~'`, `'\<'`, and `'\>'`. POSIX.1-2017 requires conformance to historical practice; that is, that regular expression usage be consistent, and that regular expression enhancements be supported wherever regular expressions are used.

90053 **Command Line Parsing in ex**

90054 Historical *ex* command parsing was even more complex than that described here. POSIX.1-2017
90055 requires the subset of the command parsing that the standard developers believed was
90056 documented and that users could reasonably be expected to use in a portable fashion, and that
90057 was historically consistent between implementations. (The discarded functionality is obscure, at
90058 best.) Historical implementations will require changes in order to comply with POSIX.1-2017;
90059 however, users are not expected to notice any of these changes. Most of the complexity in *ex*
90060 parsing is to handle three special termination cases:

90061 1. The **!**, **global**, **v**, and the filter versions of the **read** and **write** commands are delimited by
90062 <newline> characters (they can contain <vertical-line> characters that are usually shell
90063 pipes).

90064 2. The **ex**, **edit**, **next**, and **visual** in open and visual mode commands all take *ex* commands,
90065 optionally containing <vertical-line> characters, as their first arguments.

90066 3. The **s** command takes a regular expression as its first argument, and uses the delimiting
90067 characters to delimit the command.

90068 Historically, <vertical-line> characters in the **+***command* argument of the **ex**, **edit**, **next**, **vi**, and
90069 **visual** commands, and in the *pattern* and *replacement* parts of the **s** command, did not delimit the
90070 command, and in the filter cases for **read** and **write**, and the **!**, **global**, and **v** commands, they did
90071 not delimit the command at all. For example, the following commands are all valid:

```
90072 :edit +25 | s/abc/ABC/ file.c
90073 :s/ | /PIPE/
90074 :read !spell % | columnate
90075 :global/pattern/p | l
90076 :s/a/b/ | s/c/d | set
```

90077 Historically, empty or <blank> filled lines in **.exrc** files and **source**d files (as well as *EXINIT*
90078 variables and *ex* command scripts) were treated as default commands; that is, **print** commands.
90079 POSIX.1-2017 specifically requires that they be ignored when encountered in **.exrc** and **source**d
90080 files to eliminate a common source of new user error.

90081 Historically, *ex* commands with multiple adjacent (or <blank>-separated) vertical lines were
90082 handled oddly when executed from *ex* mode. For example, the command **|||** <carriage-return>,
90083 when the cursor was on line 1, displayed lines 2, 3, and 5 of the file. In addition, the command **|**
90084 would only display the line after the next line, instead of the next two lines. The former worked
90085 more logically when executed from *vi* mode, and displayed lines 2, 3, and 4. POSIX.1-2017
90086 requires the *vi* behavior; that is, a single default command and line number increment for each
90087 command separator, and trailing <newline> characters after <vertical-line> separators are
90088 discarded.

90089 Historically, *ex* permitted a single extra <colon> as a leading command character; for example,
90090 **:g/pattern/:p** was a valid command. POSIX.1-2017 generalizes this to require that any number of
90091 leading <colon> characters be stripped.

90092 Historically, any prefix of the **delete** command could be followed without intervening <blank>
90093 characters by a flag character because in the command **d p**, *p* is interpreted as the buffer *p*.
90094 POSIX.1-2017 requires conformance to historical practice.

90095 Historically, the **k** command could be followed by the mark name without intervening <blank>
90096 characters. POSIX.1-2017 requires conformance to historical practice.

90097 Historically, the **s** command could be immediately followed by flag and option characters; for
90098 example, **s/e/E/|s|sgc3p** was a valid command. However, flag characters could not stand alone;

for example, the commands **sp** and **s l** would fail, while the command **sgp** and **s gl** would succeed. (Obviously, the '#' flag character was used as a delimiter character if it followed the command.) Another issue was that option characters had to precede flag characters even when the command was fully specified; for example, the command **s/e/E/pg** would fail, while the command **s/e/E/gp** would succeed. POSIX.1-2017 requires conformance to historical practice.

Historically, the first command name that had a prefix matching the input from the user was the executed command; for example, **ve**, **ver**, and **vers** all executed the **version** command. Commands were in a specific order, however, so that **a** matched **append**, not **abbreviate**. POSIX.1-2017 requires conformance to historical practice. The restriction on command search order for implementations with extensions is to avoid the addition of commands such that the historical prefixes would fail to work portably.

Historical implementations of *ex* and *vi* did not correctly handle multiple *ex* commands, separated by <vertical-line> characters, that entered or exited visual mode or the editor. Because implementations of *vi* exist that do not exhibit this failure mode, POSIX.1-2017 does not permit it.

The requirement that alphabetic command names consist of all following alphabetic characters up to the next non-alphabetic character means that alphabetic command names must be separated from their arguments by one or more non-alphabetic characters, normally a <blank> or '!' character, except as specified for the exceptions, the **delete**, **k**, and **s** commands.

Historically, the repeated execution of the *ex* default **print** commands (<control>-D, *eof*, <newline>, <carriage-return>) erased any prompting character and displayed the next lines without scrolling the terminal; that is, immediately below any previously displayed lines. This provided a cleaner presentation of the lines in the file for the user. POSIX.1-2017 does not require this behavior because it may be impossible in some situations; however, implementations are strongly encouraged to provide this semantic if possible.

Historically, it was possible to change files in the middle of a command, and have the rest of the command executed in the new file; for example:

```
:edit +25 file.c | s/abc/ABC/ | 1
```

was a valid command, and the substitution was attempted in the newly edited file. POSIX.1-2017 requires conformance to historical practice. The following commands are examples that exercise the *ex* parser:

```
echo 'foo | bar' > file1; echo 'foo/bar' > file2;
vi
:edit +1 | s/|/PIPE/ | w file1 | e file2 | 1 | s/\//SLASH/ | wq
```

Historically, there was no protection in editor implementations to avoid *ex* **global**, **v**, **@**, or ***** commands changing edit buffers during execution of their associated commands. Because this would almost invariably result in catastrophic failure of the editor, and implementations exist that do exhibit these problems, POSIX.1-2017 requires that changing the edit buffer during a **global** or **v** command, or during a **@** or ***** command for which there will be more than a single execution, be an error. Implementations supporting multiple edit buffers simultaneously are strongly encouraged to apply the same semantics to switching between buffers as well.

The *ex* command quoting required by POSIX.1-2017 is a superset of the quoting in historical implementations of the editor. For example, it was not historically possible to escape a <blank> in a filename; for example, **:edit foo\\\ bar** would report that too many filenames had been entered for the edit command, and there was no method of escaping a <blank> in the first argument of an **edit**, **ex**, **next**, or **visual** command at all. POSIX.1-2017 extends historical practice, requiring that quoting behavior be made consistent across all *ex* commands, except for

the **map**, **unmap**, **abbreviate**, and **unabbreviate** commands, which historically used <control>-V instead of <backslash> characters for quoting. For those four commands, POSIX.1-2017 requires conformance to historical practice.

Backslash quoting in *ex* is non-intuitive. <backslash>-escapes are ignored unless they escape a special character; for example, when performing *file* argument expansion, the string `"\\%"` is equivalent to `'\%'`, not "`\<current pathname>`". This can be confusing for users because <backslash> is usually one of the characters that causes shell expansion to be performed, and therefore shell quoting rules must be taken into consideration. Generally, quoting characters are only considered if they escape a special character, and a quoting character must be provided for each layer of parsing for which the character is special. As another example, only a single <backslash> is necessary for the `'\l'` sequence in substitute replacement patterns, because the character `'l'` is not special to any parsing layer above it.

<control>-V quoting in *ex* is slightly different from backslash quoting. In the four commands where <control>-V quoting applies (**abbreviate**, **unabbreviate**, **map**, and **unmap**), any character may be escaped by a <control>-V whether it would have a special meaning or not. POSIX.1-2017 requires conformance to historical practice.

Historical implementations of the editor did not require delimiters within character classes to be escaped; for example, the command **:s/[/]//** on the string `"xxx/yyy"` would delete the `'/'` from the string. POSIX.1-2017 disallows this historical practice for consistency and because it places a large burden on implementations by requiring that knowledge of regular expressions be built into the editor parser.

Historically, quoting <newline> characters in *ex* commands was handled inconsistently. In most cases, the <newline> character always terminated the command, regardless of any preceding escape character, because <backslash> characters did not escape <newline> characters for most *ex* commands. However, some *ex* commands (for example, **s**, **map**, and **abbreviation**) permitted <newline> characters to be escaped (although in the case of **map** and **abbreviation**, <control>-V characters escaped them instead of <backslash> characters). This was true in not only the command line, but also **.exrc** and **source**d files. For example, the command:

```
map = foo<control-V><newline>bar
```

would succeed, although it was sometimes difficult to get the <control>-V and the inserted <newline> passed to the *ex* parser. For consistency and simplicity of specification, POSIX.1-2017 requires that it be possible to escape <newline> characters in *ex* commands at all times, using <backslash> characters for most *ex* commands, and using <control>-V characters for the **map** and **abbreviation** commands. For example, the command **print**<newline>**list** is required to be parsed as the single command **print**<newline>**list**. While this differs from historical practice, POSIX.1-2017 developers believed it unlikely that any script or user depended on the historical behavior.

Historically, an error in a command specified using the **−c** option did not cause the rest of the **−c** commands to be discarded. POSIX.1-2017 disallows this for consistency with mapped keys, the **@**, **global**, **source**, and **v** commands, the *EXINIT* environment variable, and the **.exrc** files.

Input Editing in ex

One of the common uses of the historical *ex* editor is over slow network connections. Editors that run in canonical mode can require far less traffic to and from, and far less processing on, the host machine, as well as more easily supporting block-mode terminals. For these reasons, POSIX.1-2017 requires that *ex* be implemented using canonical mode input processing, as was done historically.

POSIX.1-2017 does not require the historical 4 BSD input editing characters ``word erase'' or ``literal next''. For this reason, it is unspecified how they are handled by *ex*, although they must have the required effect. Implementations that resolve them after the line has been ended using a <newline> or <control>-M character, and implementations that rely on the underlying system terminal support for this processing, are both conforming. Implementations are strongly urged to use the underlying system functionality, if at all possible, for compatibility with other system text input interfaces.

Historically, when the *eof* character was used to decrement the **autoindent** level, the cursor moved to display the new end of the **autoindent** characters, but did not move the cursor to a new line, nor did it erase the <control>-D character from the line. POSIX.1-2017 does not specify that the cursor remain on the same line or that the rest of the line is erased; however, implementations are strongly encouraged to provide the best possible user interface; that is, the cursor should remain on the same line, and any <control>-D character on the line should be erased.

POSIX.1-2017 does not require the historical 4 BSD input editing character ``reprint'', traditionally <control>-R, which redisplayed the current input from the user. For this reason, and because the functionality cannot be implemented after the line has been terminated by the user, POSIX.1-2017 makes no requirements about this functionality. Implementations are strongly urged to make this historical functionality available, if possible.

Historically, <control>-Q did not perform a literal next function in *ex*, as it did in *vi*. POSIX.1-2017 requires conformance to historical practice to avoid breaking historical *ex* scripts and **.exrc** files.

eof

Whether the *eof* character immediately modifies the **autoindent** characters in the prompt is left unspecified so that implementations can conform in the presence of systems that do not support this functionality. Implementations are encouraged to modify the line and redisplay it immediately, if possible.

The specification of the handling of the *eof* character differs from historical practice only in that *eof* characters are not discarded if they follow normal characters in the text input. Historically, they were always discarded.

Command Descriptions in ex

Historically, several commands (for example, **global**, **v**, **visual**, **s**, **write**, **wq**, **yank**, **!**, **<**, **>**, **&**, and **~**) were executable in empty files (that is, the default address(es) were 0), or permitted explicit addresses of 0 (for example, 0 was a valid address, or 0,0 was a valid range). Addresses of 0, or command execution in an empty file, make sense only for commands that add new text to the edit buffer or write commands (because users may wish to write empty files). POSIX.1-2017 requires this behavior for such commands and disallows it otherwise, for consistency and simplicity of specification.

A count to an *ex* command has been historically corrected to be no greater than the last line in a

file; for example, in a five-line file, the command **1,6print** would fail, but the command **1print300** would succeed. POSIX.1-2017 requires conformance to historical practice.

Historically, the use of flags in *ex* commands could be obscure. General historical practice was as described by POSIX.1-2017, but there were some special cases. For instance, the **list**, **number**, and **print** commands ignored trailing address offsets; for example, **3p +++#** would display line 3, and 3 would be the current line after the execution of the command. The **open** and **visual** commands ignored both the trailing offsets and the trailing flags. Also, flags specified to the **open** and **visual** commands interacted badly with the **list** edit option, and setting and then unsetting it during the open/visual session would cause *vi* to stop displaying lines in the specified format. For consistency and simplicity of specification, POSIX.1-2017 does not permit any of these exceptions to the general rule.

POSIX.1-2017 uses the word *copy* in several places when discussing buffers. This is not intended to imply implementation.

Historically, *ex* users could not specify numeric buffers because of the ambiguity this would cause; for example, in the command **3 delete 2**, it is unclear whether 2 is a buffer name or a *count*. POSIX.1-2017 requires conformance to historical practice by default, but does not preclude extensions.

Historically, the contents of the unnamed buffer were frequently discarded after commands that did not explicitly affect it; for example, when using the **edit** command to switch files. For consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior.

The *ex* utility did not historically have access to the numeric buffers, and, furthermore, deleting lines in *ex* did not modify their contents. For example, if, after doing a delete in *vi*, the user switched to *ex*, did another delete, and then switched back to *vi*, the contents of the numeric buffers would not have changed. POSIX.1-2017 requires conformance to historical practice. Numeric buffers are described in the *ex* utility in order to confine the description of buffers to a single location in POSIX.1-2017.

The metacharacters that trigger shell expansion in *file* arguments match historical practice, as does the method for doing shell expansion. Implementations wishing to provide users with the flexibility to alter the set of metacharacters are encouraged to provide a **shellmeta** string edit option.

Historically, *ex* commands executed from *vi* refreshed the screen when it did not strictly need to do so; for example, **:!date > /dev/null** does not require a screen refresh because the output of the UNIX *date* command requires only a single line of the screen. POSIX.1-2017 requires that the screen be refreshed if it has been overwritten, but makes no requirements as to how an implementation should make that determination. Implementations may prompt and refresh the screen regardless.

Abbreviate

Historical practice was that characters that were entered as part of an abbreviation replacement were subject to **map** expansions, the **showmatch** edit option, further abbreviation expansions, and so on; that is, they were logically pushed onto the terminal input queue, and were not a simple replacement. POSIX.1-2017 requires conformance to historical practice. Historical practice was that whenever a non-word character (that had not been escaped by a <control>-V) was entered after a word character, *vi* would check for abbreviations. The check was based on the type of the character entered before the word character of the word/non-word pair that triggered the check. The word character of the word/non-word pair that triggered the check and all characters entered before the trigger pair that were of that type were included in the check, with the exception of <blank> characters, which always delimited the abbreviation.

This means that, for the abbreviation to work, the *lhs* must end with a word character, there can be no transitions from word to non-word characters (or *vice versa*) other than between the last and next-to-last characters in the *lhs*, and there can be no <blank> characters in the *lhs*. In addition, because of the historical quoting rules, it was impossible to enter a literal <control>-V in the *lhs*. POSIX.1-2017 requires conformance to historical practice. Historical implementations did not inform users when abbreviations that could never be used were entered; implementations are strongly encouraged to do so.

For example, the following abbreviations will work:

```
:ab (p  REPLACE
:ab p   REPLACE
:ab ((p REPLACE
```

The following abbreviations will not work:

```
:ab (   REPLACE
:ab (pp REPLACE
```

Historical practice is that words on the *vi* colon command line were subject to abbreviation expansion, including the arguments to the **abbrev** (and more interestingly) the **unabbrev** command. Because there are implementations that do not do abbreviation expansion for the first argument to those commands, this is permitted, but not required, by POSIX.1-2017. However, the following sequence:

```
:ab foo bar
:ab foo baz
```

resulted in the addition of an abbreviation of `"baz"` for the string `"bar"` in historical *ex*/*vi*, and the sequence:

```
:ab foo1 bar
:ab foo2 bar
:unabbreviate foo2
```

deleted the abbreviation `"foo1"`, not `"foo2"`. These behaviors are not permitted by POSIX.1-2017 because they clearly violate the expectations of the user.

It was historical practice that <control>-V, not <backslash>, characters be interpreted as escaping subsequent characters in the **abbreviate** command. POSIX.1-2017 requires conformance to historical practice; however, it should be noted that an abbreviation containing a <blank> will never work.

Append

Historically, any text following a <vertical-line> command separator after an **append**, **change**, or **insert** command became part of the insert text. For example, in the command:

```
:g/pattern/append|stuff1
```

a line containing the text `"stuff1"` would be appended to each line matching pattern. It was also historically valid to enter:

```
:append|stuff1
stuff2
.
```

and the text on the *ex* command line would be appended along with the text inserted after it. There was an historical bug, however, that the user had to enter two terminating lines (the `'.'`

lines) to terminate text input mode in this case. POSIX.1-2017 requires conformance to historical practice, but disallows the historical need for multiple terminating lines.

Change

See the RATIONALE for the **append** command. Historical practice for cursor positioning after the change command when no text is input, is as described in POSIX.1-2017. However, one System V implementation is known to have been modified such that the cursor is positioned on the first address specified, and not on the line before the first address. POSIX.1-2017 disallows this modification for consistency.

Historically, the **change** command did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by POSIX.1-2017.

Change Directory

A common extension in *ex* implementations is to use the elements of a **cdpath** edit option as prefix directories for *path* arguments to **chdir** that are relative pathnames and that do not have `'.'` or `"..."` as their first component. Elements in the **cdpath** edit option are <colon>-separated. The initial value of the **cdpath** edit option is the value of the shell *CDPATH* environment variable. This feature was not included in POSIX.1-2017 because it does not exist in any of the implementations considered historical practice.

Copy

Historical implementations of *ex* permitted copies to lines inside of the specified range; for example, **:2,5copy3** was a valid command. POSIX.1-2017 requires conformance to historical practice.

Delete

POSIX.1-2017 requires support for the historical parsing of a **delete** command followed by flags, without any intervening <blank> characters. For example:

1dp Deletes the first line and prints the line that was second.

1delep As for **1dp**.

1d Deletes the first line, saving it in buffer *p*.

1d p1l (Pee-one-ell.) Deletes the first line, saving it in buffer *p*, and listing the line that was second.

Edit

Historically, any *ex* command could be entered as a **+***command* argument to the **edit** command, although some (for example, **insert** and **append**) were known to confuse historical implementations. For consistency and simplicity of specification, POSIX.1-2017 requires that any command be supported as an argument to the **edit** command.

Historically, the command argument was executed with the current line set to the last line of the file, regardless of whether the **edit** command was executed from visual mode or not. POSIX.1-2017 requires conformance to historical practice.

Historically, the **+***command* specified to the **edit** and **next** commands was delimited by the first <blank>, and there was no way to quote them. For consistency, POSIX.1-2017 requires that the usual *ex* backslash quoting be provided.

Historically, specifying the **+***command* argument to the edit command required a filename to be specified as well; for example, **:edit +100** would always fail. For consistency and simplicity of specification, POSIX.1-2017 does not permit this usage to fail for that reason.

Historically, only the cursor position of the last file edited was remembered by the editor. POSIX.1-2017 requires that this be supported; however, implementations are permitted to remember and restore the cursor position for any file previously edited.

File

Historical versions of the *ex* editor **file** command displayed a current line and number of lines in the edit buffer of 0 when the file was empty, while the *vi* <control>-G command displayed a current line and number of lines in the edit buffer of 1 in the same situation. POSIX.1-2017 does not permit this discrepancy, instead requiring that a message be displayed indicating that the file is empty.

Global

The two-pass operation of the **global** and **v** commands is not intended to imply implementation, only the required result of the operation.

The current line and column are set as specified for the individual *ex* commands. This requirement is cumulative; that is, the current line and column must track across all the commands executed by the **global** or **v** commands.

Insert

See the RATIONALE for the **append** command.

Historically, **insert** could not be used with an address of zero; that is, not when the edit buffer was empty. POSIX.1-2017 requires that this command behave consistently with the **append** command.

Join

The action of the **join** command in relation to the special characters is only defined for the POSIX locale because the correct amount of white space after a period varies; in Japanese none is required, in French only a single space, and so on.

List

The historical output of the **list** command was potentially ambiguous. The standard developers believed correcting this to be more important than adhering to historical practice, and POSIX.1-2017 requires unambiguous output.

Map

Historically, command mode maps only applied to command names; for example, if the character `'x'` was mapped to `'y'`, the command **fx** searched for the `'x'` character, not the `'y'` character. POSIX.1-2017 requires this behavior. Historically, entering <control>-V as the first character of a *vi* command was an error. Several implementations have extended the semantics of *vi* such that <control>-V means that the subsequent command character is not mapped. This is permitted, but not required, by POSIX.1-2017. Regardless, using <control>-V to escape the second or later character in a sequence of characters that might match a **map** command, or any character in text input mode, is historical practice, and stops the entered keys from matching a map. POSIX.1-2017 requires conformance to historical practice.

Historical implementations permitted digits to be used as a **map** command *lhs*, but then ignored the map. POSIX.1-2017 requires that the mapped digits not be ignored.

The historical implementation of the **map** command did not permit **map** commands that were more than a single character in length if the first character was printable. This behavior is permitted, but not required, by POSIX.1-2017.

Historically, mapped characters were remapped unless the **remap** edit option was not set, or the prefix of the mapped characters matched the mapping characters; for example, in the **map**:

```
:map ab abcd
```

the characters "`ab`" were used as is and were not remapped, but the characters "`cd`" were mapped if appropriate. This can cause infinite loops in the *vi* mapping mechanisms. POSIX.1-2017 requires conformance to historical practice, and that such loops be interruptible.

Text input maps had the same problems with expanding the *lhs* for the *ex* **map!** and **unmap!** command as did the *ex* **abbreviate** and **unabbreviate** commands. See the RATIONALE for the *ex* **abbreviate** command. POSIX.1-2017 requires similar modification of some historical practice for the **map** and **unmap** commands, as described for the **abbreviate** and **unabbreviate** commands.

Historically, **map**s that were subsets of other **map**s behaved differently depending on the order in which they were defined. For example:

```
:map! ab     short
:map! abc    long
```

would always translate the characters "`ab`" to "`short`", regardless of how fast the characters "`abc`" were entered. If the entry order was reversed:

```
:map! abc    long
:map! ab     short
```

the characters "`ab`" would cause the editor to pause, waiting for the completing '`c`' character, and the characters might never be mapped to "`short`". For consistency and simplicity of specification, POSIX.1-2017 requires that the shortest match be used at all times.

The length of time the editor spends waiting for the characters to complete the *lhs* is unspecified because the timing capabilities of systems are often inexact and variable, and it may depend on other factors such as the speed of the connection. The time should be long enough for the user to be able to complete the sequence, but not long enough for the user to have to wait. Some implementations of *vi* have added a **keytime** option, which permits users to set the number of 0,1 seconds the editor waits for the completing characters. Because mapped terminal function and cursor keys tend to start with an <ESC> character, and <ESC> is the key ending *vi* text input mode, **map**s starting with <ESC> characters are generally exempted from this timeout period, or, at least timed out differently.

Mark

Historically, users were able to set the ``previous context'' marks explicitly. In addition, the *ex* commands **'** and **`** and the *vi* commands **'**, **`**, **`'**, and **`` ` `` all referred to the same mark. In addition, the previous context marks were not set if the command, with which the address setting the mark was associated, failed. POSIX.1-2017 requires conformance to historical practice. Historically, if marked lines were deleted, the mark was also deleted, but would reappear if the change was undone. POSIX.1-2017 requires conformance to historical practice.

The description of the special events that set the ` and ' marks matches historical practice. For example, historically the command **/a/,/b/** did not set the ` and ' marks, but the command

90447 **/a/,/b/delete** did.

90448 **Next**

90449 Historically, any *ex* command could be entered as a **+***command* argument to the **next** command,
90450 although some (for example, **insert** and **append**) were known to confuse historical
90451 implementations. POSIX.1-2017 requires that any command be permitted and that it behave as
90452 specified. The **next** command can accept more than one file, so usage such as:

90453 `next `ls [abc] `

90454 is valid; it need not be valid for the **edit** or **read** commands, for example, because they expect
90455 only one filename.

90456 Historically, the **next** command behaved differently from the **:rewind** command in that it
90457 ignored the force flag if the **autowrite** flag was set. For consistency, POSIX.1-2017 does not
90458 permit this behavior.

90459 Historically, the **next** command positioned the cursor as if the file had never been edited before,
90460 regardless. POSIX.1-2017 does not permit this behavior, for consistency with the **edit** command.

90461 Implementations wanting to provide a counterpart to the **next** command that edited the
90462 previous file have used the command **prev[ious],** which takes no *file* argument. POSIX.1-2017
90463 does not require this command.

90464 **Open**

90465 Historically, the **open** command would fail if the **open** edit option was not set. POSIX.1-2017
90466 does not mention the **open** edit option and does not require this behavior. Some historical
90467 implementations do not permit entering open mode from open or visual mode, only from *ex*
90468 mode. For consistency, POSIX.1-2017 does not permit this behavior.

90469 Historically, entering open mode from the command line (that is, *vi* **+open**) resulted in
90470 anomalous behaviors; for example, the *ex* file and *set* commands, and the *vi* command
90471 <control>-G did not work. For consistency, POSIX.1-2017 does not permit this behavior.

90472 Historically, the **open** command only permitted `'/'` characters to be used as the search pattern
90473 delimiter. For consistency, POSIX.1-2017 requires that the search delimiters used by the **s**, **global**,
90474 and **v** commands be accepted as well.

90475 **Preserve**

90476 The **preserve** command does not historically cause the file to be considered unmodified for the
90477 purposes of future commands that may exit the editor. POSIX.1-2017 requires conformance to
90478 historical practice.

90479 Historical documentation stated that mail was not sent to the user when preserve was executed;
90480 however, historical implementations did send mail in this case. POSIX.1-2017 requires
90481 conformance to the historical implementations.

90482 **Print**

90483 The writing of NUL by the **print** command is not specified as a special case because the standard
90484 developers did not want to require *ex* to support NUL characters. Historically, characters were
90485 displayed using the ARPA standard mappings, which are as follows:

90486 1. Printable characters are left alone.

90487 2. Control characters less than \177 are represented as `'^'` followed by the character offset
90488 from the `'@'` character in the ASCII map; for example, \007 is represented as `'^G'`.

90489 3. \177 is represented as `'^'` followed by `'?'`.

90490 The display of characters having their eighth bit set was less standard. Existing implementations
90491 use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed bytes that had their
90492 eighth bit set as the two characters `"M-"` followed by the seven-bit display as described above.)
90493 The latter probably has the best claim to historical practice because it was used for the **−v** option
90494 of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

90495 No specific display format is required by POSIX.1-2017.

90496 Explicit dependence on the ASCII character set has been avoided where possible, hence the use
90497 of the phrase an ``implementation-defined multi-character sequence'' for the display of non-
90498 printable characters in preference to the historical usage of, for instance, `"^I"` for the <tab>.
90499 Implementations are encouraged to conform to historical practice in the absence of any strong
90500 reason to diverge.

90501 Historically, all *ex* commands beginning with the letter `'p'` could be entered using capitalized
90502 versions of the commands; for example, **P[rint]**, **Pre[serve]**, and **Pu[t]** were all valid command
90503 names. POSIX.1-2017 permits, but does not require, this historical practice because capital forms
90504 of the commands are used by some implementations for other purposes.

90505 **Put**

90506 Historically, an *ex* **put** command, executed from open or visual mode, was the same as the open
90507 or visual mode **P** command, if the buffer was named and was cut in character mode, and the
90508 same as the **p** command if the buffer was named and cut in line mode. If the unnamed buffer
90509 was the source of the text, the entire line from which the text was taken was usually **put**, and the
90510 buffer was handled as if in line mode, but it was possible to get extremely anomalous behavior.
90511 In addition, using the **Q** command to switch into *ex* mode, and then doing a **put** often resulted in
90512 errors as well, such as appending text that was unrelated to the (supposed) contents of the
90513 buffer. For consistency and simplicity of specification, POSIX.1-2017 does not permit these
90514 behaviors. All *ex* **put** commands are required to operate in line mode, and the contents of the
90515 buffers are not altered by changing the mode of the editor.

90516 **Read**

90517 Historically, an *ex* **read** command executed from open or visual mode, executed in an empty file,
90518 left an empty line as the first line of the file. For consistency and simplicity of specification,
90519 POSIX.1-2017 does not permit this behavior. Historically, a **read** in open or visual mode from a
90520 program left the cursor at the last line read in, not the first. For consistency, POSIX.1-2017 does
90521 not permit this behavior.

90522 Historical implementations of *ex* were unable to undo **read** commands that read from the output
90523 of a program. For consistency, POSIX.1-2017 does not permit this behavior.

90524 Historically, the *ex* and *vi* message after a successful **read** or **write** command specified
90525 ``characters'', not ``bytes''. POSIX.1-2017 requires that the number of bytes be displayed, not the

number of characters, because it may be difficult in multi-byte implementations to determine the number of characters read. Implementations are encouraged to clarify the message displayed to the user.

Historically, reads were not permitted on files other than type regular, except that FIFO files could be read (probably only because they did not exist when *ex* and *vi* were originally written). Because the historical *ex* evaluated **read!** and **read !** equivalently, there can be no optional way to force the read. POSIX.1-2017 permits, but does not require, this behavior.

Recover

Some historical implementations of the editor permitted users to recover the edit buffer contents from a previous edit session, and then exit without saving those contents (or explicitly discarding them). The intent of POSIX.1-2017 in requiring that the edit buffer be treated as already modified is to prevent this user error.

Rewind

Historical implementations supported the **rewind** command when the user was editing the first file in the list; that is, the file that the **rewind** command would edit. POSIX.1-2017 requires conformance to historical practice.

Substitute

Historically, *ex* accepted an **r** option to the **s** command. The effect of the **r** option was to use the last regular expression used in any command as the pattern, the same as the ~ command. The **r** option is not required by POSIX.1-2017. Historically, the **c** and **g** options were toggled; for example, the command **:s/abc/def/** was the same as **s/abc/def/ccccgggg**. For simplicity of specification, POSIX.1-2017 does not permit this behavior.

The tilde command is often used to replace the last search RE. For example, in the sequence:

```
s/red/blue/
/green
~
```

the ~ command is equivalent to:

```
s/green/blue/
```

Historically, *ex* accepted all of the following forms:

```
s/abc/def/
s/abc/def
s/abc/
s/abc
```

POSIX.1-2017 requires conformance to this historical practice.

The **s** command presumes that the '^' character only occupies a single column in the display. Much of the *ex* and *vi* specification presumes that the <space> only occupies a single column in the display. There are no known character sets for which this is not true.

Historically, the final column position for the substitute commands was based on previous column movements; a search for a pattern followed by a substitution would leave the column position unchanged, while a 0 command followed by a substitution would change the column position to the first non-<blank>. For consistency and simplicity of specification, POSIX.1-2017 requires that the final column position always be set to the first non-<blank>.

Set

Historical implementations redisplayed all of the options for each occurrence of the **all** keyword. POSIX.1-2017 permits, but does not require, this behavior.

Tag

No requirement is made as to where *ex* and *vi* shall look for the file referenced by the tag entry. Historical practice has been to look for the path found in the **tags** file, based on the current directory. A useful extension found in some implementations is to look based on the directory containing the tags file that held the entry, as well. No requirement is made as to which reference for the tag in the tags file is used. This is deliberate, in order to permit extensions such as multiple entries in a tags file for a tag.

Because users often specify many different tags files, some of which need not be relevant or exist at any particular time, POSIX.1-2017 requires that error messages about problem tags files be displayed only if the requested tag is not found, and then, only once for each time that the **tag** edit option is changed.

The requirement that the current edit buffer be unmodified is only necessary if the file indicated by the tag entry is not the same as the current file (as defined by the current pathname). Historically, the file would be reloaded if the filename had changed, as well as if the filename was different from the current pathname. For consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior, requiring that the name be the only factor in the decision.

Historically, *vi* only searched for tags in the current file from the current cursor to the end of the file, and therefore, if the **wrapscan** option was not set, tags occurring before the current cursor were not found. POSIX.1-2017 considers this a bug, and implementations are required to search for the first occurrence in the file, regardless.

Undo

The **undo** description deliberately uses the word ``modified''. The **undo** command is not intended to undo commands that replace the contents of the edit buffer, such as **edit**, **next**, **tag**, or **recover**.

Cursor positioning after the **undo** command was inconsistent in the historical *vi*, sometimes attempting to restore the original cursor position (**global**, **undo**, and **v** commands), and sometimes, in the presence of maps, placing the cursor on the last line added or changed instead of the first. POSIX.1-2017 requires a simplified behavior for consistency and simplicity of specification.

Version

The **version** command cannot be exactly specified since there is no widely-accepted definition of what the version information should contain. Implementations are encouraged to do something reasonably intelligent.

Write

Historically, the *ex* and *vi* message after a successful **read** or **write** command specified ``characters'', not ``bytes''. POSIX.1-2017 requires that the number of bytes be displayed, not the number of characters because it may be difficult in multi-byte implementations to determine the number of characters written. Implementations are encouraged to clarify the message displayed to the user.

Implementation-defined tests are permitted so that implementations can make additional checks; for example, for locks or file modification times.

Historically, attempting to append to a nonexistent file caused an error. It has been left unspecified in POSIX.1-2017 to permit implementations to let the **write** succeed, so that the append semantics are similar to those of the historical *csh*.

Historical *vi* permitted empty edit buffers to be written. However, since the way *vi* got around dealing with ``empty'' files was to always have a line in the edit buffer, no matter what, it wrote them as files of a single, empty line. POSIX.1-2017 does not permit this behavior.

Historically, *ex* restored standard output and standard error to their values as of when *ex* was invoked, before writes to programs were performed. This could disturb the terminal configuration as well as be a security issue for some terminals. POSIX.1-2017 does not permit this, requiring that the program output be captured and displayed as if by the *ex* **print** command.

Adjust Window

Historically, the line count was set to the value of the **scroll** option if the type character was end-of-file. This feature was broken on most historical implementations long ago, however, and is not documented anywhere. For this reason, POSIX.1-2017 is resolutely silent.

Historically, the **z** command was <blank>-sensitive and **z +** and **z −** did different things than **z+** and **z−** because the type could not be distinguished from a flag. (The commands **z .** and **z =** were historically invalid.) POSIX.1-2017 requires conformance to this historical practice.

Historically, the **z** command was further <blank>-sensitive in that the *count* could not be <blank>-delimited; for example, the commands **z= 5** and **z− 5** were also invalid. Because the *count* is not ambiguous with respect to either the type character or the flags, this is not permitted by POSIX.1-2017.

Escape

Historically, *ex* filter commands only read the standard output of the commands, letting standard error appear on the terminal as usual. The *vi* utility, however, read both standard output and standard error. POSIX.1-2017 requires the latter behavior for both *ex* and *vi*, for consistency.

Shift Left and Shift Right

Historically, it was possible to add shift characters to increase the effect of the command; for example, **<<<** outdented (or **>>>** indented) the lines 3 levels of indentation instead of the default 1. POSIX.1-2017 requires conformance to historical practice.

90644 **<control>-D**

90645 Historically, the <control>-D command erased the prompt, providing the user with an unbroken
90646 presentation of lines from the edit buffer. This is not required by POSIX.1-2017; implementations
90647 are encouraged to provide it if possible. Historically, the <control>-D command took, and then
90648 ignored, a *count*. POSIX.1-2017 does not permit this behavior.

90649 **Write Line Number**

90650 Historically, the *ex* **=** command, when executed in *ex* mode in an empty edit buffer, reported 0,
90651 and from open or visual mode, reported 1. For consistency and simplicity of specification,
90652 POSIX.1-2017 does not permit this behavior.

90653 **Execute**

90654 Historically, *ex* did not correctly handle the inclusion of text input commands (that is, **append**,
90655 **insert**, and **change**) in executed buffers. POSIX.1-2017 does not permit this exclusion for
90656 consistency.

90657 Historically, the logical contents of the buffer being executed did not change if the buffer itself
90658 were modified by the commands being executed; that is, buffer execution did not support self-
90659 modifying code. POSIX.1-2017 requires conformance to historical practice.

90660 Historically, the @ command took a range of lines, and the @ buffer was executed once per line,
90661 with the current line (`'.'`) set to each specified line. POSIX.1-2017 requires conformance to
90662 historical practice.

90663 Some historical implementations did not notice if errors occurred during buffer execution. This,
90664 coupled with the ability to specify a range of lines for the *ex* @ command, makes it trivial to
90665 cause them to drop **core**. POSIX.1-2017 requires that implementations stop buffer execution if
90666 any error occurs, if the specified line doesn't exist, or if the contents of the edit buffer itself are
90667 replaced (for example, the buffer executes the *ex* **:edit** command).

90668 **Regular Expressions in ex**

90669 Historical practice is that the characters in the replacement part of the last **s** command ‡that is,
90670 those matched by entering a `'~'` in the regular expression ‡were not further expanded by the
90671 regular expression engine. So, if the characters contained the string `"a.,"` they would match
90672 `'a'` followed by `".,"` and not `'a'` followed by any character. POSIX.1-2017 requires
90673 conformance to historical practice.

90674 **Edit Options in ex**

90675 The following paragraphs describe the historical behavior of some edit options that were not, for
90676 whatever reason, included in POSIX.1-2017. Implementations are strongly encouraged to only
90677 use these names if the functionality described here is fully supported.

90678 **extended** The **extended** edit option has been used in some implementations of *vi* to provide
90679 extended regular expressions instead of basic regular expressions This option was
90680 omitted from POSIX.1-2017 because it is not widespread historical practice.

90681 **flash** The **flash** edit option historically caused the screen to flash instead of beeping on
90682 error. This option was omitted from POSIX.1-2017 because it is not found in some
90683 historical implementations.

90684 **hardtabs** The **hardtabs** edit option historically defined the number of columns between
90685 hardware tab settings. This option was omitted from POSIX.1-2017 because it was
90686 believed to no longer be generally useful.

90687 **modeline** The **modeline** (sometimes named **modelines**) edit option historically caused *ex* or
90688 *vi* to read the five first and last lines of the file for editor commands. This option is
90689 a security problem, and vendors are strongly encouraged to delete it from
90690 historical implementations.

90691 **open** The **open** edit option historically disallowed the *ex* **open** and **visual** commands.
90692 This edit option was omitted because these commands are required by
90693 POSIX.1-2017.

90694 **optimize** The **optimize** edit option historically expedited text throughput by setting the
90695 terminal to not do automatic <carriage-return> characters when printing more
90696 than one logical line of output. This option was omitted from POSIX.1-2017
90697 because it was intended for terminals without addressable cursors, which are
90698 rarely, if ever, still used.

90699 **ruler** The **ruler** edit option has been used in some implementations of *vi* to present a
90700 current row/column ruler for the user. This option was omitted from POSIX.1-2017
90701 because it is not widespread historical practice.

90702 **sourceany** The **sourceany** edit option historically caused *ex* or *vi* to source start-up files that
90703 were owned by users other than the user running the editor. This option is a
90704 security problem, and vendors are strongly encouraged to remove it from their
90705 implementations.

90706 **timeout** The **timeout** edit option historically enabled the (now standard) feature of only
90707 waiting for a short period before returning keys that could be part of a macro. This
90708 feature was omitted from POSIX.1-2017 because its behavior is now standard, it is
90709 not widely useful, and it was rarely documented.

90710 **verbose** The **verbose** edit option has been used in some implementations of *vi* to cause *vi* to
90711 output error messages for common errors; for example, attempting to move the
90712 cursor past the beginning or end of the line instead of only alerting the screen. (The
90713 historical *vi* only alerted the terminal and presented no message for such errors.
90714 The historical editor option **terse** did not select when to present error messages, it
90715 only made existing error messages more or less verbose.) This option was omitted
90716 from POSIX.1-2017 because it is not widespread historical practice; however,
90717 implementors are encouraged to use it if they wish to provide error messages for
90718 naive users.

90719 **wraplen** The **wraplen** edit option has been used in some implementations of *vi* to specify an
90720 automatic margin measured from the left margin instead of from the right margin.
90721 This is useful when multiple screen sizes are being used to edit a single file. This
90722 option was omitted from POSIX.1-2017 because it is not widespread historical
90723 practice; however, implementors are encouraged to use it if they add this
90724 functionality.

90725 **autoindent, ai**

90726 Historically, the command **0a** did not do any autoindentation, regardless of the current
90727 indentation of line 1. POSIX.1-2017 requires that any indentation present in line 1 be used.

90728 **autoprint, ap**

90729 Historically, the **autoprint** edit option was not completely consistent or based solely on
90730 modifications to the edit buffer. Exceptions were the **read** command (when reading from a file,
90731 but not from a filter), the **append**, **change**, **insert**, **global**, and **v** commands, all of which were not
90732 affected by **autoprint**, and the **tag** command, which was affected by **autoprint**. POSIX.1-2017
90733 requires conformance to historical practice.

90734 Historically, the **autoprint** option only applied to the last of multiple commands entered using
90735 <vertical-line> delimiters; for example, **delete** <newline> was affected by **autoprint**, but
90736 **delete | version** <newline> was not. POSIX.1-2017 requires conformance to historical practice.

90737 **autowrite, aw**

90738 Appending the `'!'` character to the *ex* **next** command to avoid performing an automatic write
90739 was not supported in historical implementations. POSIX.1-2017 requires that the behavior match
90740 the other *ex* commands for consistency.

90741 **ignorecase, ic**

90742 Historical implementations of case-insensitive matching (the **ignorecase** edit option) lead to
90743 counter-intuitive situations when uppercase characters were used in range expressions.
90744 Historically, the process was as follows:

90745 1. Take a line of text from the edit buffer.

90746 2. Convert uppercase to lowercase in text line.

90747 3. Convert uppercase to lowercase in regular expressions, except in character class
90748 specifications.

90749 4. Match regular expressions against text.

90750 This would mean that, with **ignorecase** in effect, the text:

90751 `The cat sat on the mat`

90752 would be matched by

90753 `/^the/`

90754 but not by:

90755 `/^[A-Z]he/`

90756 For consistency with other commands implementing regular expressions, POSIX.1-2017 does not
90757 permit this behavior.

90758 **paragraphs, para**

90759 The ISO POSIX-2:1993 standard made the default **paragraphs** and **sections** edit options
90760 implementation-defined, arguing they were historically oriented to the UNIX system *troff* text
90761 formatter, and a ``portable user'' could use the {, }, [[,]], **(**, and **)** commands in open or visual
90762 mode and have the cursor stop in unexpected places. POSIX.1-2017 specifies their values in the
90763 POSIX locale because the unusual grouping (they only work when grouped into two characters
90764 at a time) means that they cannot be used for general-purpose movement, regardless.

90765 **readonly**

90766 Implementations are encouraged to provide the best possible information to the user as to the
90767 read-only status of the file, with the exception that they should not consider the current special
90768 privileges of the process. This provides users with a safety net because they must force the
90769 overwrite of read-only files, even when running with additional privileges.

90770 The **readonly** edit option specification largely conforms to historical practice. The only
90771 difference is that historical implementations did not notice that the user had set the **readonly**
90772 edit option in cases where the file was already marked read-only for some reason, and would
90773 therefore reinitialize the **readonly** edit option the next time the contents of the edit buffer were
90774 replaced. This behavior is disallowed by POSIX.1-2017.

90775 **report**

90776 The requirement that lines copied to a buffer interact differently than deleted lines is historical
90777 practice. For example, if the **report** edit option is set to 3, deleting 3 lines will cause a report to be
90778 written, but 4 lines must be copied before a report is written.

90779 The requirement that the *ex* **global**, **v**, **open**, **undo**, and **visual** commands present reports based
90780 on the total number of lines added or deleted during the command execution, and that
90781 commands executed by the **global** and **v** commands not present reports, is historical practice.
90782 POSIX.1-2017 extends historical practice by requiring that buffer execution be treated similarly.
90783 The reasons for this are two-fold. Historically, only the report by the last command executed
90784 from the buffer would be seen by the user, as each new report would overwrite the last. In
90785 addition, the standard developers believed that buffer execution had more in common with
90786 **global** and **v** commands than it did with other *ex* commands, and should behave similarly, for
90787 consistency and simplicity of specification.

90788 **showmatch, sm**

90789 The length of time the cursor spends on the matching character is unspecified because the
90790 timing capabilities of systems are often inexact and variable. The time should be long enough for
90791 the user to notice, but not long enough for the user to become annoyed. Some implementations
90792 of *vi* have added a **matchtime** option that permits users to set the number of 0,1 second intervals
90793 the cursor pauses on the matching character.

90794 **showmode**

90795 The **showmode** option has been used in some historical implementations of *ex* and *vi* to display
90796 the current editing mode when in open or visual mode. The editing modes have generally
90797 included ``command'' and ``input'', and sometimes other modes such as ``replace'' and
90798 ``change''. The string was usually displayed on the bottom line of the screen at the far right-hand
90799 corner. In addition, a preceding `'*'` character often denoted whether the contents of the edit
90800 buffer had been modified. The latter display has sometimes been part of the **showmode** option,
90801 and sometimes based on another option. This option was not available in the 4 BSD historical

implementation of *vi*, but was viewed as generally useful, particularly to novice users, and is required by POSIX.1-2017.

The **smd** shorthand for the **showmode** option was not present in all historical implementations of the editor. POSIX.1-2017 requires it, for consistency.

Not all historical implementations of the editor displayed a mode string for command mode, differentiating command mode from text input mode by the absence of a mode string. POSIX.1-2017 permits this behavior for consistency with historical practice, but implementations are encouraged to provide a display string for both modes.

slowopen

Historically, the **slowopen** option was automatically set if the terminal baud rate was less than 1 200 baud, or if the baud rate was 1 200 baud and the **redraw** option was not set. The **slowopen** option had two effects. First, when inserting characters in the middle of a line, characters after the cursor would not be pushed ahead, but would appear to be overwritten. Second, when creating a new line of text, lines after the current line would not be scrolled down, but would appear to be overwritten. In both cases, ending text input mode would cause the screen to be refreshed to match the actual contents of the edit buffer. Finally, terminals that were sufficiently intelligent caused the editor to ignore the **slowopen** option. POSIX.1-2017 permits most historical behavior, extending historical practice to require **slowopen** behaviors if the edit option is set by the user.

tags

The default path for tags files is left unspecified as implementations may have their own **tags** implementations that do not correspond to the historical ones. The default **tags** option value should probably at least include the file **./tags**.

term

Historical implementations of *ex* and *vi* ignored changes to the **term** edit option after the initial terminal information was loaded. This is permitted by POSIX.1-2017; however, implementations are encouraged to permit the user to modify their terminal type at any time.

terse

Historically, the **terse** edit option optionally provided a shorter, less descriptive error message, for some error messages. This is permitted, but not required, by POSIX.1-2017. Historically, most common visual mode errors (for example, trying to move the cursor past the end of a line) did not result in an error message, but simply alerted the terminal. Implementations wishing to provide messages for novice users are urged to do so based on the **edit** option **verbose**, and not **terse**.

window

In historical implementations, the default for the **window** edit option was based on the baud rate as follows:

1. If the baud rate was less than 1 200, the **edit** option **w300** set the window value; for example, the line:

   ```
   set w300=12
   ```

   would set the window option to 12 if the baud rate was less than 1 200.

2. If the baud rate was equal to 1 200, the **edit** option **w1200** set the window value.
3. If the baud rate was greater than 1 200, the **edit** option **w9600** set the window value.

The **w300**, **w1200**, and **w9600** options do not appear in POSIX.1-2017 because of their dependence on specific baud rates.

In historical implementations, the size of the window displayed by various commands was related to, but not necessarily the same as, the **window** edit option. For example, the size of the window was set by the *ex* command **visual 10**, but it did not change the value of the **window** edit option. However, changing the value of the **window** edit option did change the number of lines that were displayed when the screen was repainted. POSIX.1-2017 does not permit this behavior in the interests of consistency and simplicity of specification, and requires that all commands that change the number of lines that are displayed do it by setting the value of the **window** edit option.

wrapmargin, wm

Historically, the **wrapmargin** option did not affect maps inserting characters that also had associated *count*s; for example **:map K 5aABC DEF**. Unfortunately, there are widely used maps that depend on this behavior. For consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior.

Historically, **wrapmargin** was calculated using the column display width of all characters on the screen. For example, an implementation using `"^I"` to represent <tab> characters when the **list** edit option was set, where `'^'` and `'I'` each took up a single column on the screen, would calculate the **wrapmargin** based on a value of 2 for each <tab>. The **number** edit option similarly changed the effective length of the line as well. POSIX.1-2017 requires conformance to historical practice.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed, removing the **+***command* and **–** options.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

In the **map** command description, the sequence **#***digit* is added.

The **directory**, **edcompatible**, **redraw**, and **slowopen** edit options are added.

The *ex* utility is extensively changed for alignment with the IEEE P1003.2b draft standard. This includes changes as a result of the IEEE PASC Interpretations 1003.2 #31, #38, #49, #50, #51, #52, #55, #56, #57, #61, #62, #63, #64, #65, and #78.

The **–l** option is removed.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/23 is applied, correcting a URL.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/8 is applied, making an editorial correction in the EXTENDED DESCRIPTION.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/9 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if an operand is `'–'`.

Austin Group Interpretation 1003.1-2001 #036 is applied, clarifying the behavior for BREs.

Austin Group Interpretation 1003.1-2001 #121 is applied, clarifying the *ex* **write** command.

Austin Group Interpretation 1003.1-2001 #156 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0093 [584] is applied.

NAME

expand ‡'convert tabs to spaces

SYNOPSIS

```
expand [−t tablist] [file...]
```

DESCRIPTION

The *expand* utility shall write files or the standard input to the standard output with <tab> characters replaced with one or more <space> characters needed to pad to the next tab stop. Any <backspace> characters shall be copied to the output and cause the column position count for tab stop calculations to be decremented; the column position count shall not be decremented below zero.

OPTIONS

The *expand* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−t *tablist* Specify the tab stops. The application shall ensure that the argument *tablist* consists of either a single positive decimal integer or a list of tabstops. If a single number is given, tabs shall be set that number of column positions apart instead of the default 8.

If a list of tabstops is given, the application shall ensure that it consists of a list of two or more positive decimal integers, separated by <blank> or <comma> characters, in ascending order. The <tab> characters shall be set at those specific column positions. Each tab stop *N* shall be an integer value greater than zero, and the list is in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line.

In the event of *expand* having to process a <tab> at a position beyond the last of those specified in a multiple tab-stop list, the <tab> shall be replaced by a single <space> in the output.

OPERANDS

The following operand shall be supported:

file The pathname of a text file to be used as input.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *expand*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab> and <space> characters, and for the determination of the width in column positions each character would

90948 occupy on an output device.

90949 *LC_MESSAGES*

90950 Determine the locale that should be used to affect the format and contents of
90951 diagnostic messages written to standard error.

90952 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

90953 **ASYNCHRONOUS EVENTS**

90954 Default.

90955 **STDOUT**

90956 The standard output shall be equivalent to the input files with <tab> characters converted into
90957 the appropriate number of <space> characters.

90958 **STDERR**

90959 The standard error shall be used only for diagnostic messages.

90960 **OUTPUT FILES**

90961 None.

90962 **EXTENDED DESCRIPTION**

90963 None.

90964 **EXIT STATUS**

90965 The following exit values shall be returned:

90966 0 Successful completion

90967 >0 An error occurred.

90968 **CONSEQUENCES OF ERRORS**

90969 The *expand* utility shall terminate with an error message and non-zero exit status upon
90970 encountering difficulties accessing one of the *file* operands.

90971 **APPLICATION USAGE**

90972 None.

90973 **EXAMPLES**

90974 None.

90975 **RATIONALE**

90976 The *expand* utility is useful for preprocessing text files (before sorting, looking at specific
90977 columns, and so on) that contain <tab> characters.

90978 See XBD Section 3.103 (on page 50).

90979 The *tablist* option-argument consists of integers in ascending order. Utility Syntax Guideline 8
90980 mandates that *expand* shall accept the integers (within the single argument) separated using
90981 either <comma> or <blank> characters.

90982 Earlier versions of this standard allowed the following form in the SYNOPSIS:

90983 `expand [-tabstop][-tab1,tab2,...,tabn][file ...]`

90984 This form is no longer specified by POSIX.1-2017 but may be present in some implementations.

90985 **FUTURE DIRECTIONS**

90986 None.

SEE ALSO

tabs, *unexpand*

XBD Section 3.103 (on page 50), Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

The *LC_CTYPE* environment variable description is updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *expand* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

expr — evaluate arguments as an expression

SYNOPSIS

```
expr operand...
```

DESCRIPTION

The *expr* utility shall evaluate an expression and write the result to standard output.

OPTIONS

None.

OPERANDS

The single expression evaluated by *expr* shall be formed from the *operand* operands, as described in the EXTENDED DESCRIPTION section. The application shall ensure that each of the expression operator symbols:

```
(  )  |  &  =  >  >=  <  <=  !=  +  -  *  /  %  :
```

and the symbols *integer* and *string* in the table are provided as separate arguments to *expr*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *expr*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions and by the string comparison operators.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *expr* utility shall evaluate the expression and write the result, followed by a <newline>, to standard output.

91045 **STDERR**

91046 The standard error shall be used only for diagnostic messages.

91047 **OUTPUT FILES**

91048 None.

91049 **EXTENDED DESCRIPTION**

91050 The formation of the expression to be evaluated is shown in the following table. The symbols
91051 *expr*, *expr1*, and *expr2* represent expressions formed from *integer* and *string* symbols and the
91052 expression operator symbols (all separate arguments) by recursive application of the constructs
91053 described in the table. The expressions are listed in order of decreasing precedence, with equal-
91054 precedence operators grouped between horizontal lines. All of the operators shall be left-
91055 associative.

91056

Expression	Description
integer	An argument consisting only of an (optional) unary minus followed by digits.
string	A string argument; see below.
(*expr*)	Grouping symbols. Any expression can be placed within parentheses. Parentheses can be nested to a depth of {EXPR_NEST_MAX}.
expr1 : *expr2*	Matching expression; see below.
expr1 * *expr2*	Multiplication of decimal integer-valued arguments.
expr1 / *expr2*	Integer division of decimal integer-valued arguments, producing an integer result.
expr1 % *expr2*	Remainder of integer division of decimal integer-valued arguments.
expr1 + *expr2*	Addition of decimal integer-valued arguments.
expr1 − *expr2*	Subtraction of decimal integer-valued arguments.
	Returns the result of a decimal integer comparison if both arguments are integers; otherwise, returns the result of a string comparison using the locale-specific collation sequence. The result of each comparison is 1 if the specified relationship is true, or 0 if the relationship is false.
expr1 = *expr2*	Equal.
expr1 > *expr2*	Greater than.
expr1 >= *expr2*	Greater than or equal.
expr1 < *expr2*	Less than.
expr1 <= *expr2*	Less than or equal.
expr1 != *expr2*	Not equal.
expr1 & *expr2*	Returns the evaluation of *expr1* if neither expression evaluates to null or zero; otherwise, returns zero.
expr1 | *expr2*	Returns the evaluation of *expr1* if it is neither null nor zero; otherwise, returns the evaluation of *expr2* if it is not null; otherwise, zero.

91087 **Matching Expression**

91088 The `':'` matching operator shall compare the string resulting from the evaluation of *expr1* with
91089 the regular expression pattern resulting from the evaluation of *expr2*. Regular expression syntax
91090 shall be that defined in XBD Section 9.3 (on page 183), except that all patterns are anchored to
91091 the beginning of the string (that is, only sequences starting at the first character of a string are
91092 matched by the regular expression) and, therefore, it is unspecified whether `'^'` is a special
91093 character in that context. Usually, the matching operator shall return a string representing the
91094 number of characters matched (`'0'` on failure). Alternatively, if the pattern contains at least one
91095 regular expression subexpression `"[\(...\)]"`, the string matched by the back-reference
91096 expression `"\1"` shall be returned. If the back-reference expression `"\1"` does not match, then
91097 the null string shall be returned.

91098 **Identification as Integer or String**

91099 An argument or the value of a subexpression that consists only of an optional unary minus
91100 followed by digits is a candidate for treatment as an integer if it is used as the left argument to
91101 the `|` operator or as either argument to any of the following operators: `&` `=` `>` `>=` `<` `<=` `!=` `+`
91102 `-` `*` `/` `%`. Otherwise, the argument or subexpression value shall be treated as a string.

91103 The use of string arguments **length**, **substr**, **index**, or **match** produces unspecified results.

91104 **EXIT STATUS**

91105 The following exit values shall be returned:

91106 0 The *expression* evaluates to neither null nor zero.

91107 1 The *expression* evaluates to null or zero.

91108 2 Invalid *expression*.

91109 >2 An error occurred.

91110 **CONSEQUENCES OF ERRORS**

91111 Default.

91112 **APPLICATION USAGE**

91113 The *expr* utility has a rather difficult syntax:

91114 Many of the operators are also shell control operators or reserved words, so they have to
91115 be escaped on the command line.

91116 Each part of the expression is composed of separate arguments, so liberal usage of <blank>
91117 characters is required. For example:

91118

91119

Invalid	Valid
`expr 1+2`	`expr 1 + 2`
`expr "1 + 2"`	`expr 1 + 2`
`expr 1 + (2 * 3)`	`expr 1 + \( 2 \* 3 \)`

91120

91121

91122

91123 In many cases, the arithmetic and string features provided as part of the shell command
91124 language are easier to use than their equivalents in *expr*. Newly written scripts should avoid
91125 *expr* in favor of the new features within the shell; see Section 2.5 (on page 2349) and Section 2.6.4
91126 (on page 2358).

91127 After argument processing by the shell, *expr* is not required to be able to tell the difference
91128 between an operator and an operand except by the value. If `"$a"` is `'='`, the command:

91129 `expr "$a" = '='`

looks like:

```
expr = = =
```

as the arguments are passed to *expr* (and they all may be taken as the `'='` operator). The following works reliably:

```
expr "X$a" = X=
```

Also note that this volume of POSIX.1-2017 permits implementations to extend utilities. The *expr* utility permits the integer arguments to be preceded with a unary minus. This means that an integer argument could look like an option. Therefore, the conforming application must employ the `"--"` construct of Guideline 10 of XBD Section 12.2 (on page 216) to protect its operands if there is any chance the first operand might be a negative integer (or any string with a leading minus).

For testing string equality the *test* utility is preferred over *expr*, as it is usually implemented as a shell built-in. However, the functionality is not quite the same because the *expr* `=` and `!=` operators check whether strings collate equally, whereas *test* checks whether they are identical. Therefore, they can produce different results in locales where the collation sequence does not have a total ordering of all characters (see XBD Section 7.3.2, on page 147).

EXAMPLES

The following command:

```
a=$(expr "$a" + 1)
```

adds 1 to the variable *a*.

The following command, for `"$a"` equal to either **/usr/abc/file** or just **file**:

```
expr $a : '.*/\(.*\)' \| $a
```

returns the last segment of a pathname (that is, **file**). Applications should avoid the character `'/'` used alone as an argument; *expr* may interpret it as the division operator.

The following command:

```
expr "//$a" : '.*/\(.*\)'
```

is a better representation of the previous example. The addition of the `"//"` characters eliminates any ambiguity about the division operator and simplifies the whole expression. Also note that pathnames may contain characters contained in the *IFS* variable and should be quoted to avoid having `"$a"` expand into multiple arguments.

The following command:

```
expr "X$VAR" : '.*' - 1
```

returns the number of characters in *VAR*.

RATIONALE

In an early proposal, EREs were used in the matching expression syntax. This was changed to BREs to avoid breaking historical applications.

The use of a leading <circumflex> in the BRE is unspecified because many historical implementations have treated it as a special character, despite their system documentation. For example:

```
expr foo : ^foo      expr ^foo : ^foo
```

return 3 and 0, respectively, on those systems; their documentation would imply the reverse.

Thus, the anchoring condition is left unspecified to avoid breaking historical scripts relying on this undocumented feature.

FUTURE DIRECTIONS

None.

Section 2.5 (on page 2349), Section 2.6.4 (on page 2358)

XBD Section 7.3.2 (on page 147), Chapter 8 (on page 173), Section 9.3 (on page 183), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The *expr* utility is aligned with the IEEE P1003.2b draft standard, to include resolution of IEEE PASC Interpretation 1003.2 #104.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #036 is applied, clarifying the behavior for BREs.

The SYNOPSIS and OPERANDS sections are revised to explicitly state that the name of each of the operands is *operand*.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0094 [942], XCU/TC2-2008/0095 [709], XCU/TC2-2008/0096 [942], XCU/TC2-2008/0097 [963], and XCU/TC2-2008/0098 [942] are applied.

CHANGE HISTORY

First released in Issue 2.

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/24 is applied, changing the STDERR section from ``None.'' to ``Not used.'' for alignment withSection 1.4 (on page 2336).

NAME

fc — process the command history list

SYNOPSIS

UP

```
fc [−r] [−e editor] [first [last]]
fc −l [−nr] [first [last]]
fc −s [old=new] [first]
```

DESCRIPTION

The *fc* utility shall list, or shall edit and re-execute, commands previously entered to an interactive *sh*.

The command history list shall reference commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command shall not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches an implementation-defined upper limit, which shall be no smaller than the value in *HISTSIZE* or 32 767 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, *fc* shall maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher.

When commands are edited (when the **−l** option is not specified), the resulting lines shall be entered at the end of the history list and then re-executed by *sh*. The *fc* command that caused the editing shall not be entered into the history list. If the editor returns a non-zero exit status, this shall suppress the entry into the history list and the command re-execution. Any command line variable assignments or redirection operators used with *fc* shall affect both the *fc* command itself as well as the command that results; for example:

```
fc −s −− −1 2>/dev/null
```

reinvokes the previous command, suppressing standard error for both *fc* and the previous command.

OPTIONS

The *fc* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−e *editor* Use the editor named by *editor* to edit the commands. The *editor* string is a utility name, subject to search via the *PATH* variable (see XBD Chapter 8, on page 173). The value in the *FCEDIT* variable shall be used as a default when **−e** is not specified. If *FCEDIT* is null or unset, *ed* shall be used as the editor.

−l (The letter ell.) List the commands rather than invoking an editor on them. The commands shall be written in the sequence indicated by the *first* and *last* operands, as affected by **−r**, with each command preceded by the command number.

−n Suppress command numbers when listing with **−l**.

−r Reverse the order of the commands listed (with **−l**) or edited (with neither **−l** nor **−s**).

−s Re-execute the command without invoking an editor.

OPERANDS

The following operands shall be supported:

first, *last* Select the commands to list or edit. The number of previous commands that can be accessed shall be determined by the value of the *HISTSIZE* variable. The value of *first* or *last* or both shall be one of the following:

[+]*number* A positive number representing a command number; command numbers can be displayed with the **−l** option.

−number A negative decimal number representing the command that was executed *number* of commands previously. For example, −1 is the immediately previous command.

string A string indicating the most recently entered command that begins with that string. If the *old=new* operand is not also specified with **−s**, the string form of the *first* operand cannot contain an embedded <equals-sign>.

When the synopsis form with **−s** is used:

If *first* is omitted, the previous command shall be used.

For the synopsis forms without **−s**:

If *last* is omitted, *last* shall default to the previous command when **−l** is specified; otherwise, it shall default to *first*.

If *first* and *last* are both omitted, the previous 16 commands shall be listed or the previous single command shall be edited (based on the **−l** option).

If *first* and *last* are both present, all of the commands from *first* to *last* shall be edited (without **−l**) or listed (with **−l**). Editing multiple commands shall be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If *first* represents a newer command than *last*, the commands shall be listed or edited in reverse sequence, equivalent to using **−r**. For example, the following commands on the first line are equivalent to the corresponding commands on the second:

```
fc −r 10 20    fc    30 40
fc    20 10    fc −r 40 30
```

When a range of commands is used, it shall not be an error to specify *first* or *last* values that are not in the history list; *fc* shall substitute the value representing the oldest or newest command in the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10:

```
fc −l
fc 1 99
```

shall list and edit, respectively, all ten commands.

old=new Replace the first occurrence of string *old* in the commands to be re-executed by the string *new*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fc*:

FCEDIT This variable, when expanded by the shell, shall determine the default value for the **−e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be used as the editor.

HISTFILE Determine a pathname naming a command history file. If the *HISTFILE* variable is not set, the shell may attempt to access or create a file **.sh_history** in the directory referred to by the *HOME* environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history ``file'' in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when *fc* or *sh* first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the *ENV* variable, or implementation-defined system start-up files. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Therefore, it is implementation-defined whether changes made to *HISTFILE* after the history file has been initialized are effective. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set *HISTFILE*; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file.

HISTSIZE Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE* after the history file has been initialized are effective.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–l** option is used to list commands, the format of each command in the list shall be as follows:

```
"%d\t%s\n", <line number>, <command>
```

If both the **–l** and **–n** options are specified, the format of each command shall be:

```
"\t%s\n", <command>
```

If the <*command*> consists of more than one line, the lines after the first shall be displayed as:

```
"\t%s\n", <continued-command>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion of the listing.

>0 An error occurred.

Otherwise, the exit status shall be that of the commands executed by *fc*.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since editors sometimes use file descriptors as integral parts of their editing, redirecting their file descriptors as part of the *fc* command can produce unexpected results. For example, if *vi* is the *FCEDIT* editor, the command:

```
fc –s | more
```

does not work correctly on many systems.

Users on windowing systems may want to have separate history files for each window by setting *HISTFILE* as follows:

```
HISTFILE=$HOME/.sh_hist$$
```

EXAMPLES

None.

RATIONALE

This utility is based on the *fc* built-in of the KornShell.

An early proposal specified the **–e** option as **[**–**e** *editor* **[***old***=** *new* **]]**, which is not historical practice. Historical practice in *fc* of either **[**–**e** *editor***]** or **[**–**e** – **[** *old***=** *new* **]]** is acceptable, but not both together. To clarify this, a new option **–s** was introduced replacing the **[**–**e** –**]**. This resolves

the conflict and makes *fc* conform to the Utility Syntax Guidelines.

HISTFILE Some implementations of the KornShell check for the superuser and do not create a history file unless *HISTFILE* is set. This is done primarily to avoid creating unlinked files in the root file system when logging in during single-user mode. *HISTFILE* must be set for the superuser to have history.

HISTSIZE Needed to limit the size of history files. It is the intent of the standard developers that when two shells share the same history file, commands that are entered in one shell shall be accessible by the other shell. Because of the difficulties of synchronization over a network, the exact nature of the interaction is unspecified.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the settings the user has for *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user can influence its characteristics. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Because of these situations, the text requires the initialization process to be implementation-defined.

Consideration was given to omitting the *fc* utility in favor of the command line editing feature in *sh*. For example, in *vi* editing mode, typing "<ESC> v" is equivalent to:

```
EDITOR=vi fc
```

However, the *fc* utility allows the user the flexibility to edit multiple commands simultaneously (such as *fc* 10 20) and to use editors other than those supported by *sh* for command line editing.

In the KornShell, the alias **r** (``re-do'') is preset to *fc* **−e** − (equivalent to the POSIX *fc* **−s**). This is probably an easier command name to remember than *fc* (``fix command''), but it does not meet the Utility Syntax Guidelines. Renaming *fc* to *hist* or *redo* was considered, but since this description closely matches historical KornShell practice already, such a renaming was seen as gratuitous. Users are free to create aliases whenever odd historical names such as *fc*, *awk*, *cat*, *grep*, or *yacc* are standardized by POSIX.

Command numbers have no ordering effects; they are like serial numbers. The **−r** option and *−number* operand address the sequence of command execution, regardless of serial numbers. So, for example, if the command number wrapped back to 1 at some arbitrary point, there would be no ambiguity associated with traversing the wrap point. For example, if the command history were:

```
32766: echo 1
32767: echo 2
1: echo 3
```

the number −2 refers to command 32 767 because it is the second previous command, regardless of serial number.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

In the ENVIRONMENT VARIABLES section, the text ``user's home directory'' is updated to ``directory referred to by the *HOME* environment variable''.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

fg — run jobs in the foreground

SYNOPSIS

UP

```
fg [job_id]
```

DESCRIPTION

If job control is enabled (see the description of *set* −**m**), the *fg* utility shall move a background job from the current environment (see Section 2.12, on page 2381) into the foreground.

Using *fg* to place a job into the foreground shall remove its process ID from the list of those ``known in the current shell execution environment''; see Section 2.9.3.1 (on page 2370).

OPTIONS

None.

OPERANDS

The following operand shall be supported:

job_id Specify the job to be run as a foreground job. If no *job_id* operand is given, the *job_id* for the job that was most recently suspended, placed in the background, or run as a background job shall be used. The format of *job_id* is described in XBD Section 3.204 (on page 66).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fg*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *fg* utility shall write the command line of the job to standard output in the following format:

```
"%s\n", <command>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If job control is disabled, the *fg* utility shall exit with an error and no job shall be placed in the foreground.

APPLICATION USAGE

The *fg* utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for *bg*. For this reason, *fg* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The extensions to the shell specified in this volume of POSIX.1-2017 have mostly been based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of POSIX.1-2017 to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The JC marking is removed from the SYNOPSIS since job control is mandatory is this version.

NAME

file ‡'determine file type

SYNOPSIS

```
file [–dh] [–M file] [–m file] file...
file –i [–h] file...
```

DESCRIPTION

The *file* utility shall perform a series of tests in sequence on each specified *file* in an attempt to classify it:

1. If *file* does not exist, cannot be read, or its file status could not be determined, the output shall indicate that the file was processed, but that its type could not be determined.
2. If the file is not a regular file, its file type shall be identified. The file types directory, FIFO, socket, block special, and character special shall be identified as such. Other implementation-defined file types may also be identified. If *file* is a symbolic link, by default the link shall be resolved and *file* shall test the type of file referenced by the symbolic link. (See the **–h** and **–i** options below.)
3. If the length of *file* is zero, it shall be identified as an empty file.
4. The *file* utility shall examine an initial segment of *file* and shall make a guess at identifying its contents based on position-sensitive tests. (The answer is not guaranteed to be correct; see the **–d**, **–M**, and **–m** options below.)
5. The *file* utility shall examine *file* and make a guess at identifying its contents based on context-sensitive default system tests. (The answer is not guaranteed to be correct.)
6. The file shall be identified as a data file.

If *file* does not exist, cannot be read, or its file status could not be determined, the output shall indicate that the file was processed, but that its type could not be determined.

If *file* is a symbolic link, by default the link shall be resolved and *file* shall test the type of file referenced by the symbolic link.

OPTIONS

The *file* utility shall conform to XBD Section 12.2 (on page 216), except that the order of the **–m**, **–d**, and **–M** options shall be significant.

The following options shall be supported by the implementation:

–d Apply any position-sensitive default system tests and context-sensitive default system tests to the file. This is the default if no **–M** or **–m** option is specified.

–h When a symbolic link is encountered, identify the file as a symbolic link. If **–h** is not specified and *file* is a symbolic link that refers to a nonexistent file, *file* shall identify the file as a symbolic link, as if **–h** had been specified.

–i If a file is a regular file, do not attempt to classify the type of the file further, but identify the file as specified in the STDOUT section.

–M *file* Specify the name of a file containing position-sensitive tests that shall be applied to a file in order to classify it (see the EXTENDED DESCRIPTION). No position-sensitive default system tests nor context-sensitive default system tests shall be applied unless the **–d** option is also specified.

91580 **−m** *file* Specify the name of a file containing position-sensitive tests that shall be applied to
91581 a file in order to classify it (see the EXTENDED DESCRIPTION).

91582 If the **−m** option is specified without specifying the **−d** option or the **−M** option, position-
91583 sensitive default system tests shall be applied after the position-sensitive tests specified by the
91584 **−m** option. If the **−M** option is specified with the **−d** option, the **−m** option, or both, or the **−m**
91585 option is specified with the **−d** option, the concatenation of the position-sensitive tests specified
91586 by these options shall be applied in the order specified by the appearance of these options. If a
91587 **−M** or **−m** *file* option-argument is −, the results are unspecified.

91588 **OPERANDS**

91589 The following operand shall be supported:

91590 *file* A pathname of a file to be tested.

91591 **STDIN**

91592 The standard input shall be used if a *file* operand is `'−'` and the implementation treats the `'−'`
91593 as meaning standard input. Otherwise, the standard input shall not be used.

91594 **INPUT FILES**

91595 The *file* can be any file type.

91596 **ENVIRONMENT VARIABLES**

91597 The following environment variables shall affect the execution of *file*:

91598 *LANG* Provide a default value for the internationalization variables that are unset or null.
91599 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
91600 variables used to determine the values of locale categories.)

91601 *LC_ALL* If set to a non-empty string value, override the values of all the other
91602 internationalization variables.

91603 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
91604 characters (for example, single-byte as opposed to multi-byte characters in
91605 arguments and input files).

91606 *LC_MESSAGES*
91607 Determine the locale that should be used to affect the format and contents of
91608 diagnostic messages written to standard error and informative messages written to
91609 standard output.

91610 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

91611 **ASYNCHRONOUS EVENTS**

91612 Default.

91613 **STDOUT**

91614 In the POSIX locale, the following format shall be used to identify each operand, *file* specified:

91615 `"%s: %s\n", <file>, <type>`

91616 The values for <*type*> are unspecified, except that in the POSIX locale, if *file* is identified as one
91617 of the types listed in the following table, <*type*> shall contain (but is not limited to) the
91618 corresponding string, unless the file is identified by a position-sensitive test specified by a **−M** or
91619 **−m** option. Each <space> shown in the strings shall be exactly one <space>.

Table 4-9 File Utility Output Strings

If *file* is:	<*type*> shall contain the string:	Notes
Nonexistent	cannot open	
Block special	block special	1
Character special	character special	1
Directory	directory	1
FIFO	fifo	1
Socket	socket	1
Symbolic link	symbolic link to	1
Regular file	regular file	1,2
Empty regular file	empty	3
Regular file that cannot be read	cannot open	3
Executable binary	executable	3,4,6
ar archive library (see *ar*)	archive	3,4,6
Extended *cpio* format (see *pax*)	cpio archive	3,4,6
Extended *tar* format (see **ustar** in *pax*)	tar archive	3,4,6
Shell script	commands text	3,5,6
C-language source	c program text	3,5,6
FORTRAN source	fortran program text	3,5,6
Regular file whose type cannot be determined	data	3

Notes:

1. This is a file type test.
2. This test is applied only if the **−i** option is specified.
3. This test is applied only if the **−i** option is not specified.
4. This is a position-sensitive default system test.
5. This is a context-sensitive default system test.
6. Position-sensitive default system tests and context-sensitive default system tests are not applied if the **−M** option is specified unless the **−d** option is also specified.

In the POSIX locale, if *file* is identified as a symbolic link (see the **−h** option), the following alternative output format shall be used:

`"%s: %s %s\n", <file>, <type>, <contents of link>"`

If the file named by the *file* operand does not exist, cannot be read, or the type of the file named by the *file* operand cannot be determined, this shall not be considered an error that affects the exit status.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

A file specified as an option-argument to the **−m** or **−M** options shall contain one position-sensitive test per line, which shall be applied to the file. If the test succeeds, the message field of the line shall be printed and no further tests shall be applied, with the exception that tests on immediately following lines beginning with a single `'>'` character shall be applied.

Each line shall be composed of the following four <tab>-separated fields. (Implementations may allow any combination of one or more white-space characters other than <newline> to act as field separators.)

offset An unsigned number (optionally preceded by a single `'>'` character) specifying the *offset*, in bytes, of the value in the file that is to be compared against the *value* field of the line. If the file is shorter than the specified offset, the test shall fail.

If the *offset* begins with the character `'>'`, the test contained in the line shall not be applied to the file unless the test on the last line for which the *offset* did not begin with a `'>'` was successful. By default, the *offset* shall be interpreted as an unsigned decimal number. With a leading 0x or 0X, the *offset* shall be interpreted as a hexadecimal number; otherwise, with a leading 0, the *offset* shall be interpreted as an octal number.

type The type of the value in the file to be tested. The type shall consist of the type specification characters `d`, `s`, and `u`, specifying signed decimal, string, and unsigned decimal, respectively.

The *type* string shall be interpreted as the bytes from the file starting at the specified *offset* and including the same number of bytes specified by the *value* field. If insufficient bytes remain in the file past the *offset* to match the *value* field, the test shall fail.

The type specification characters `d` and `u` can be followed by an optional unsigned decimal integer that specifies the number of bytes represented by the type. The type specification characters `d` and `u` can be followed by an optional `C`, `S`, `I`, or `L`, indicating that the value is of type **char**, **short**, **int**, or **long**, respectively.

The default number of bytes represented by the type specifiers `d`, `f`, and `u` shall correspond to their respective C-language types as follows. If the system claims conformance to the C-Language Development Utilities option, those specifiers shall correspond to the default sizes used in the *c99* utility. Otherwise, the default sizes shall be implementation-defined.

For the type specifier characters `d` and `u`, the default number of bytes shall correspond to the size of a basic integer type of the implementation. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **char**, **short**, **int**, or **long**. These numbers can also be specified by an application as the characters `C`, `S`, `I`, and `L`, respectively. The byte order used when interpreting numeric values is implementation-defined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.

All type specifiers, except for `s`, can be followed by a mask specifier of the form &*number*. The mask value shall be AND'ed with the value of the input file before the comparison with the *value* field of the line is made. By default, the mask shall be interpreted as an unsigned decimal number. With a leading 0x or 0X, the mask shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading

0, the mask shall be interpreted as an unsigned octal number.

The strings **byte**, **short**, **long**, and **string** shall also be supported as type fields, being interpreted as `dC`, `dS`, `dL`, and `s`, respectively.

value The *value* to be compared with the value from the file.

If the specifier from the type field is `s` or **string**, then interpret the value as a string. Otherwise, interpret it as a number. If the value is a string, then the test shall succeed only when a string value exactly matches the bytes from the file.

If the *value* is a string, it can contain the following sequences:

character The <backslash>-escape sequences as specified in XBD Table 5-1 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequence `'\ '` (the <backslash> character followed by a <space> character) shall be recognized to represent a <space> character. The results of using any other character, other than an octal digit, following the <backslash> are unspecified.

octal Octal sequences that can be used to represent characters with specific coded values. An octal sequence shall consist of a <backslash> followed by the longest sequence of one, two, or three octal-digit characters (01234567).

By default, any value that is not a string shall be interpreted as a signed decimal number. Any such value, with a leading 0x or 0X, shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading zero, the value shall be interpreted as an unsigned octal number.

If the value is not a string, it can be preceded by a character indicating the comparison to be performed. Permissible characters and the comparisons they specify are as follows:

= The test shall succeed if the value from the file equals the *value* field.

< The test shall succeed if the value from the file is less than the *value* field.

> The test shall succeed if the value from the file is greater than the *value* field.

`&` The test shall succeed if all of the set bits in the *value* field are set in the value from the file.

`^` The test shall succeed if at least one of the set bits in the *value* field is not set in the value from the file.

`x` The test shall succeed if the file is large enough to contain a value of the type specified starting at the offset specified.

message The *message* to be printed if the test succeeds. The *message* shall be interpreted using the notation for the *printf* formatting specification; see *printf*. If the *value* field was a string, then the value from the file shall be the argument for the *printf* formatting specification; otherwise, the value from the file shall be the argument.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *file* utility can only be required to guess at many of the file types because only exhaustive testing can determine some types with certainty. For example, binary data on some implementations might match the initial segment of an executable or a *tar* archive.

Note that the table indicates that the output contains the stated string. Systems may add text before or after the string. For executables, as an example, the machine architecture and various facts about how the file was link-edited may be included. Note also that on systems that recognize shell script files starting with `"#!"` as executable files, these may be identified as executable binary files rather than as shell scripts.

EXAMPLES

Determine whether an argument is a binary executable file:

```
file -- "$1" | grep -q ':.*executable' &&
    printf "%s is executable.\n" "$1"
```

RATIONALE

The **-f** option was omitted because the same effect can (and should) be obtained using the *xargs* utility.

Historical versions of the *file* utility attempt to identify the following types of files: symbolic link, directory, character special, block special, socket, *tar* archive, *cpio* archive, SCCS archive, archive library, empty, *compress* output, *pack* output, binary data, C source, FORTRAN source, assembler source, *nroff/troff/eqn/tbl* source *troff* output, shell script, C shell script, English text, ASCII text, various executables, APL workspace, compiled terminfo entries, and CURSES screen images. Only those types that are reasonably well specified in POSIX or are directly related to POSIX utilities are listed in the table.

Historical systems have used a ``magic file'' named **/etc/magic** to help identify file types. Because it is generally useful for users and scripts to be able to identify special file types, the **-m** flag and a portable format for user-created magic files has been specified. No requirement is made that an implementation of *file* use this method of identifying files, only that users be permitted to add their own classifying tests.

In addition, three options have been added to historical practice. The **-d** flag has been added to permit users to cause their tests to follow any default system tests. The **-i** flag has been added to permit users to test portably for regular files in shell scripts. The **-M** flag has been added to permit users to ignore any default system tests.

The POSIX.1-2017 description of default system tests and the interaction between the **-d**, **-M**, and **-m** options did not clearly indicate that there were two types of ``default system tests''. The ``position-sensitive tests'' determine file types by looking for certain string or binary values at specific offsets in the file being examined. These position-sensitive tests were implemented in historical systems using the magic file described above. Some of these tests are now built into the *file* utility itself on some implementations so the output can provide more detail than can be provided by magic files. For example, a magic file can easily identify a **core** file on most implementations, but cannot name the program file that dropped the core. A magic file could

91790 produce output such as:

91791 `/home/dwc/core: ELF 32-bit MSB core file SPARC Version 1`

91792 but by building the test into the *file* utility, you could get output such as:

91793 `/home/dwc/core: ELF 32-bit MSB core file SPARC Version 1, from 'testprog'`

91794 These extended built-in tests are still to be treated as position-sensitive default system tests even
91795 if they are not listed in **/etc/magic** or any other magic file.

91796 The context-sensitive default system tests were always built into the *file* utility. These tests
91797 looked for language constructs in text files trying to identify shell scripts, C, FORTRAN, and
91798 other computer language source files, and even plain text files. With the addition of the **−m** and
91799 **−M** options the distinction between position-sensitive and context-sensitive default system tests
91800 became important because the order of testing is important. The context-sensitive system default
91801 tests should never be applied before any position-sensitive tests even if the **−d** option is specified
91802 before a **−m** option or **−M** option due to the high probability that the context-sensitive system
91803 default tests will incorrectly identify arbitrary text files as text files before position-sensitive tests
91804 specified by the **−m** or **−M** option would be applied to give a more accurate identification.

91805 Leaving the meaning of **−M** − and **−m** − unspecified allows an existing prototype of these
91806 options to continue to work in a backwards-compatible manner. (In that implementation, **−M** −
91807 was roughly equivalent to **−d** in POSIX.1-2017.)

91808 The historical **−c** option was omitted as not particularly useful to users or portable shell scripts.
91809 In addition, a reasonable implementation of the *file* utility would report any errors found each
91810 time the magic file is read.

91811 The historical format of the magic file was the same as that specified by the Rationale in the
91812 ISO POSIX-2: 1993 standard for the *offset*, *value*, and *message* fields; however, it used less precise
91813 type fields than the format specified by the current normative text. The new type field values are
91814 a superset of the historical ones.

91815 The following is an example magic file:

```
91816 0  short     070707              cpio archive
91817 0  short     0143561             Byte-swapped cpio archive
91818 0  string    070707              ASCII cpio archive
91819 0  long      0177555             Very old archive
91820 0  short     0177545             Old archive
91821 0  short     017437              Old packed data
91822 0  string    \037\036            Packed data
91823 0  string    \377\037            Compacted data
91824 0  string    \037\235            Compressed data
91825 >2 byte&0x80 >0                  Block compressed
91826 >2 byte&0x1f x                   %d bits
91827 0  string    \032\001            Compiled Terminfo Entry
91828 0  short     0433                Curses screen image
91829 0  short     0434                Curses screen image
91830 0  string    <ar>                System V Release 1 archive
91831 0  string    !<arch>\n__.SYMDEF  Archive random library
91832 0  string    !<arch>             Archive
91833 0  string    ARF_BEGARF          PHIGS clear text archive
91834 0  long      0x137A2950          Scalable OpenFont binary
91835 0  long      0x137A2951          Encrypted scalable OpenFont binary
```

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Options and an EXTENDED DESCRIPTION are added as specified in the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 #192 and #178 are applied.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/25 is applied, making major changes to address ambiguities raised in defect reports.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/26 is applied, making it clear in the OPTIONS section that the **−m**, **−d**, and **−M** options do not comply with Guideline 11 of the Utility Syntax Guidelines.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/10 is applied, clarifying the specification characters.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/11 is applied, allowing application developers to create portable magic files that can match characters in strings, and allowing common extensions found in existing implementations.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/12 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-4 is applied, adding further entries in the Notes column in Table 4-9.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *file* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

The EXAMPLES section is revised to correct an error with the pathname `"$1"`.

NAME

find ‡'find files

SYNOPSIS

```
find [−H|−L] path... [operand_expression...]
```

DESCRIPTION

The *find* utility shall recursively descend the directory hierarchy from each file specified by *path*, evaluating a Boolean expression composed of the primaries described in the OPERANDS section for each file encountered. Each *path* operand shall be evaluated unaltered as it was provided, including all trailing <slash> characters; all pathnames for other files encountered in the hierarchy shall consist of the concatenation of the current *path* operand, a <slash> if the current *path* operand did not end in one, and the filename relative to the *path* operand. The relative portion shall contain no dot or dot-dot components, no trailing <slash> characters, and only single <slash> characters between pathname components.

The *find* utility shall be able to descend to arbitrary depths in a file hierarchy and shall not fail due to path length limitations (unless a *path* operand specified by the application exceeds {PATH_MAX} requirements).

The *find* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *find* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

If a file is removed from or added to the directory hierarchy being searched it is unspecified whether or not *find* includes that file in its search.

OPTIONS

The *find* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

−H Cause the file information and file type evaluated for each symbolic link encountered as a *path* operand on the command line to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself. File information and type for symbolic links encountered during the traversal of a file hierarchy shall be that of the link itself.

−L Cause the file information and file type evaluated for each symbolic link encountered as a *path* operand on the command line or encountered during the traversal of a file hierarchy to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself.

Specifying more than one of the mutually-exclusive options **−H** and **−L** shall not be considered an error. The last option specified shall determine the behavior of the utility. If neither the **−H** nor the **−L** option is specified, then the file information and type for symbolic links encountered as a *path* operand on the command line or encountered during the traversal of a file hierarchy shall be that of the link itself.

OPERANDS

The following operands shall be supported:

The first operand and subsequent operands up to but not including the first operand that starts with a `'−'`, or is a `'!'` or a `'('`, shall be interpreted as *path* operands. If the first operand starts with a `'−'`, or is a `'!'` or a `'('`, the behavior is unspecified. Each *path* operand is a pathname of

a starting point in the file hierarchy.

The first operand that starts with a `'-'`, or is a `'!'` or a `'('`, and all subsequent arguments shall be interpreted as an *expression* made up of the following primaries and operators. In the descriptions, wherever *n* is used as a primary argument, it shall be interpreted as a decimal integer optionally preceded by a <plus-sign> (`'+'`) or <hyphen-minus> (`'-'`), as follows:

+n More than *n*.

n Exactly *n*.

-n Less than *n*.

The following primaries shall be supported:

-name *pattern*
The primary shall evaluate as true if the basename of the current pathname matches *pattern* using the pattern matching notation described in Section 2.13 (on page 2382). The additional rules in Section 2.13.3 (on page 2383) do not apply as this is a matching operation, not an expansion.

-path *pattern*
The primary shall evaluate as true if the current pathname matches *pattern* using the pattern matching notation described in Section 2.13 (on page 2382). The additional rules in Section 2.13.3 (on page 2383) do not apply as this is a matching operation, not an expansion.

-nouser The primary shall evaluate as true if the file belongs to a user ID for which the *getpwuid*() function defined in the System Interfaces volume of POSIX.1-2017 (or equivalent) returns NULL.

-nogroup The primary shall evaluate as true if the file belongs to a group ID for which the *getgrgid*() function defined in the System Interfaces volume of POSIX.1-2017 (or equivalent) returns NULL.

-xdev The primary shall always evaluate as true; it shall cause *find* not to continue descending past directories that have a different device ID (*st_dev*, see the *stat*() function defined in the System Interfaces volume of POSIX.1-2017). If any **-xdev** primary is specified, it shall apply to the entire expression even if the **-xdev** primary would not normally be evaluated.

-prune The primary shall always evaluate as true; it shall cause *find* not to descend the current pathname if it is a directory. If the **-depth** primary is specified, the **-prune** primary shall have no effect.

-perm [-]*mode*
The *mode* argument is used to represent file mode bits. It shall be identical in format to the *symbolic_mode* operand described in *chmod*, and shall be interpreted as follows. To start, a template shall be assumed with all file mode bits cleared. An *op* symbol of `'+'` shall set the appropriate mode bits in the template; `'-'` shall clear the appropriate bits; `'='` shall set the appropriate mode bits, without regard to the contents of the file mode creation mask of the process. The *op* symbol of `'-'` cannot be the first character of *mode*; this avoids ambiguity with the optional leading <hyphen-minus>. Since the initial mode is all bits off, there are not any symbolic modes that need to use `'-'` as the first character.

If the <hyphen-minus> is omitted, the primary shall evaluate as true when the file permission bits exactly match the value of the resulting template.

Otherwise, if *mode* is prefixed by a <hyphen-minus>, the primary shall evaluate as true if at least all the bits in the resulting template are set in the file permission bits.

−**perm** **[**−**]***onum*

If the <hyphen-minus> is omitted, the primary shall evaluate as true when the file mode bits exactly match the value of the octal number *onum* (see the description of the octal *mode* in *chmod*). Otherwise, if *onum* is prefixed by a <hyphen-minus>, the primary shall evaluate as true if at least all of the bits specified in *onum* are set. In both cases, the behavior is unspecified when *onum* exceeds 07777.

−**type** *c* The primary shall evaluate as true if the type of the file is *c*, where *c* is `'b'`, `'c'`, `'d'`, `'l'`, `'p'`, `'f'`, or `'s'` for block special file, character special file, directory, symbolic link, FIFO, regular file, or socket, respectively.

−**links** *n* The primary shall evaluate as true if the file has *n* links.

−**user** *uname* The primary shall evaluate as true if the file belongs to the user *uname.* If *uname* is a decimal integer and the *getpwnam*() (or equivalent) function does not return a valid user name, *uname* shall be interpreted as a user ID.

−**group** *gname*

The primary shall evaluate as true if the file belongs to the group *gname*. If *gname* is a decimal integer and the *getgrnam*() (or equivalent) function does not return a valid group name, *gname* shall be interpreted as a group ID.

−**size** *n***[c]** The primary shall evaluate as true if the file size in bytes, divided by 512 and rounded up to the next integer, is *n*. If *n* is followed by the character `'c'`, the size shall be in bytes.

−**atime** *n* The primary shall evaluate as true if the file access time subtracted from the initialization time, divided by 86 400 (with any remainder discarded), is *n*.

−**ctime** *n* The primary shall evaluate as true if the time of last change of file status information subtracted from the initialization time, divided by 86 400 (with any remainder discarded), is *n*.

−**mtime** *n* The primary shall evaluate as true if the file modification time subtracted from the initialization time, divided by 86 400 (with any remainder discarded), is *n*.

−**exec** *utility_name* **[***argument* ...**] ;**
−**exec** *utility_name* **[***argument* ...**]** {} +

The end of the primary expression shall be punctuated by a <semicolon> or by a <plus-sign>. Only a <plus-sign> that immediately follows an argument containing only the two characters `"{}"` shall punctuate the end of the primary expression. Other uses of the <plus-sign> shall not be treated as special.

If the primary expression is punctuated by a <semicolon>, the utility *utility_name* shall be invoked once for each pathname and the primary shall evaluate as true if the utility returns a zero value as exit status. A *utility_name* or *argument* containing only the two characters `"{}"` shall be replaced by the current pathname. If a *utility_name* or *argument* string contains the two characters `"{}"`, but not just the two characters `"{}"`, it is implementation-defined whether *find* replaces those two characters or uses the string without change.

If the primary expression is punctuated by a <plus-sign>, the primary shall always evaluate as true, and the pathnames for which the primary is evaluated shall be aggregated into sets. The utility *utility_name* shall be invoked once for each set of aggregated pathnames. Each invocation shall begin after the last pathname in the

92008 set is aggregated, and shall be completed before the *find* utility exits and before the
92009 first pathname in the next set (if any) is aggregated for this primary, but it is
92010 otherwise unspecified whether the invocation occurs before, during, or after the
92011 evaluations of other primaries. If any invocation returns a non-zero value as exit
92012 status, the *find* utility shall return a non-zero exit status. An argument containing
92013 only the two characters "{}" shall be replaced by the set of aggregated
92014 pathnames, with each pathname passed as a separate argument to the invoked
92015 utility in the same order that it was aggregated. The size of any set of two or more
92016 pathnames shall be limited such that execution of the utility does not cause the
92017 system's {ARG_MAX} limit to be exceeded. If more than one argument containing
92018 the two characters "{}" is present, the behavior is unspecified.

92019 The current directory for the invocation of *utility_name* shall be the same as the
92020 current directory when the *find* utility was started. If the *utility_name* names any of
92021 the special built-in utilities (see Section 2.14, on page 2384), the results are
92022 undefined.

92023 −**ok** *utility_name* **[***argument* ...**] ;**
92024 The −**ok** primary shall be equivalent to −**exec**, except that the use of a <plus-sign>
92025 to punctuate the end of the primary expression need not be supported, and *find*
92026 shall request affirmation of the invocation of *utility_name* using the current file as
92027 an argument by writing to standard error as described in the STDERR section. If
92028 the response on standard input is affirmative, the utility shall be invoked.
92029 Otherwise, the command shall not be invoked and the value of the −**ok** operand
92030 shall be false.

92031 −**print** The primary shall always evaluate as true; it shall cause the current pathname to
92032 be written to standard output.

92033 −**newer** *file* The primary shall evaluate as true if the modification time of the current file is
92034 more recent than the modification time of the file named by the pathname *file*.

92035 −**depth** The primary shall always evaluate as true; it shall cause descent of the directory
92036 hierarchy to be done so that all entries in a directory are acted on before the
92037 directory itself. If a −**depth** primary is not specified, all entries in a directory shall
92038 be acted on after the directory itself. If any −**depth** primary is specified, it shall
92039 apply to the entire expression even if the −**depth** primary would not normally be
92040 evaluated.

92041 The primaries can be combined using the following operators (in order of decreasing
92042 precedence):

92043 (*expression*) True if *expression* is true.

92044 **!** *expression* Negation of a primary; the unary NOT operator.

92045 *expression* **[**−**a]** *expression*
92046 Conjunction of primaries; the AND operator is implied by the juxtaposition of two
92047 primaries or made explicit by the optional −**a** operator. The second expression shall
92048 not be evaluated if the first expression is false.

92049 *expression* −**o** *expression*
92050 Alternation of primaries; the OR operator. The second expression shall not be
92051 evaluated if the first expression is true.

92052 If no *expression* is present, −**print** shall be used as the expression. Otherwise, if the given
92053 expression does not contain any of the primaries −**exec**, −**ok**, or −**print**, the given expression

92054 shall be effectively replaced by:

92055 `( given_expression ) -print`

92056 The **−user**, **−group**, and **−newer** primaries each shall evaluate their respective arguments only
92057 once.

92058 When the file type evaluated for the current file is a symbolic link, the results of evaluating the
92059 **−perm** primary are implementation-defined.

92060 **STDIN**

92061 If the **−ok** primary is used, the response shall be read from the standard input. An entire line
92062 shall be read as the response. Otherwise, the standard input shall not be used.

92063 **INPUT FILES**

92064 None.

92065 **ENVIRONMENT VARIABLES**

92066 The following environment variables shall affect the execution of *find*:

92067 *LANG* Provide a default value for the internationalization variables that are unset or null.
92068 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
92069 variables used to determine the values of locale categories.)

92070 *LC_ALL* If set to a non-empty string value, override the values of all the other
92071 internationalization variables.

92072 *LC_COLLATE*

92073 Determine the locale for the behavior of ranges, equivalence classes, and multi-
92074 character collating elements used in the pattern matching notation for the **−n**
92075 option and in the extended regular expression defined for the **yesexpr** locale
92076 keyword in the *LC_MESSAGES* category.

92077 *LC_CTYPE* This variable determines the locale for the interpretation of sequences of bytes of
92078 text data as characters (for example, single-byte as opposed to multi-byte
92079 characters in arguments), the behavior of character classes within the pattern
92080 matching notation used for the **−n** option, and the behavior of character classes
92081 within regular expressions used in the extended regular expression defined for the
92082 **yesexpr** locale keyword in the *LC_MESSAGES* category.

92083 *LC_MESSAGES*

92084 Determine the locale used to process affirmative responses, and the locale used to
92085 affect the format and contents of diagnostic messages and prompts written to
92086 standard error.

92087 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92088 *PATH* Determine the location of the *utility_name* for the **−exec** and **−ok** primaries, as
92089 described in XBD Chapter 8 (on page 173).

92090 **ASYNCHRONOUS EVENTS**

92091 Default.

92092 **STDOUT**

92093 The **−print** primary shall cause the current pathnames to be written to standard output. The
92094 format shall be:

92095 `"%s\n", <path>`

92096 **STDERR**

92097 The −**ok** primary shall write a prompt to standard error containing at least the *utility_name* to be
92098 invoked and the current pathname. In the POSIX locale, the last non-<blank> in the prompt shall
92099 be `'?'`. The exact format used is unspecified.

92100 Otherwise, the standard error shall be used only for diagnostic messages.

92101 **OUTPUT FILES**

92102 None.

92103 **EXTENDED DESCRIPTION**

92104 None.

92105 **EXIT STATUS**

92106 The following exit values shall be returned:

92107 0 All *path* operands were traversed successfully.

92108 >0 An error occurred.

92109 **CONSEQUENCES OF ERRORS**

92110 Default.

92111 **APPLICATION USAGE**

92112 When used in operands, pattern matching notation, <semicolon>, <left-parenthesis>, and
92113 <right-parenthesis> characters are special to the shell and must be quoted (see Section 2.2, on
92114 page 2346).

92115 The bit that is traditionally used for sticky (historically 01000) is specified in the −**perm** primary
92116 using the octal number argument form. Since this bit is not defined by this volume of
92117 POSIX.1-2017, applications must not assume that it actually refers to the traditional sticky bit.

92118 **EXAMPLES**

92119 1. The following commands are equivalent:

92120 ```
92121 find .
find . −print
```

92122 They both write out the entire directory hierarchy from the current directory.

92123 2. The following command:

92124 ```
find / \( −name tmp −o −name '*.xx' \) −atime +7 −exec rm {} \;
```

92125 removes all files named **tmp** or ending in **.xx** that have not been accessed for seven or
92126 more 24-hour periods.

92127 3. The following command:

92128 ```
find . −perm −o+w,+s
```

92129 prints (−**print** is assumed) the names of all files in or below the current directory, with all
92130 of the file permission bits S_ISUID, S_ISGID, and S_IWOTH set.

92131 4. The following command:

92132 ```
find . −name SCCS −prune −o −print
```

92133 recursively prints pathnames of all files in the current directory and below, but skips
92134 directories named SCCS and files in them.

5. The following command:

```
find . –print –name SCCS –prune
```

behaves as in the previous example, but prints the names of the SCCS directories.

6. The following command is roughly equivalent to the –**nt** extension to *test*:

```
if [ –n "$(find file1 –prune –newer file2)" ]; then
    printf %s\\n "file1 is newer than file2"
fi
```

7. The descriptions of –**atime**, –**ctime**, and –**mtime** use the terminology *n* ``86 400 second periods (days)''. For example, a file accessed at 23:59 is selected by:

```
find . –atime –1 –print
```

at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.

8. The following command:

```
find . ! –name . –prune –name '*.old' –exec \
    sh –c 'mv "$@" ../old/' sh {} +
```

performs the same task as:

```
mv ./*.old ./.old ./.*.old ../old/
```

while avoiding an ``Argument list too long'' error if there are a large number of files ending with **.old** and without running *mv* if there are no such files (and avoiding ``No such file or directory'' errors if **./.old** does not exist or no files match **./*.old** or **./.*.old**).

The alternative:

```
find . ! –name . –prune –name '*.old' –exec mv {} ../old/ \;
```

is less efficient if there are many files to move because it executes one *mv* command per file.

9. On systems configured to mount removable media on directories under **/media**, the following command searches the file hierarchy for files larger than 100 000 KB without searching any mounted removable media:

```
find / –path /media –prune –o –size +200000 –print
```

10. Except for the root directory, and `"//"` on implementations where `"//"` does not refer to the root directory, no pattern given to –**name** will match a <slash>, because trailing <slash> characters are ignored when computing the basename of the file under evaluation. Given two empty directories named **foo** and **bar**, the following command:

```
find foo/// bar/// –name foo –o –name 'bar?*'
```

prints only the line `"foo///"`.

RATIONALE

The –**a** operator was retained as an optional operator for compatibility with historical shell scripts, even though it is redundant with expression concatenation.

The descriptions of the `'–'` modifier on the *mode* and *onum* arguments to the –**perm** primary agree with historical practice on BSD and System V implementations. System V and BSD documentation both describe it in terms of checking additional bits; in fact, it uses the same bits, but checks for having at least all of the matching bits set instead of having exactly the matching

bits set.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because:

> Implementations may desire more descriptive prompts than those used on historical implementations.
>
> Since the historical prompt strings do not terminate with <newline> characters, there is no portable way for another program to interact with the prompts of this utility via pipes.

Therefore, an application using this prompting option relies on the system to provide the most suitable dialog directly with the user, based on the general guidelines specified.

The −**name** *file* operand was changed to use the shell pattern matching notation so that *find* is consistent with other utilities using pattern matching.

The −**size** operand refers to the size of a file, rather than the number of blocks it may occupy in the file system. The intent is that the *st_size* field defined in the System Interfaces volume of POSIX.1-2017 should be used, not the *st_blocks* found in historical implementations. There are at least two reasons for this:

1. In both System V and BSD, *find* only uses *st_size* in size calculations for the operands specified by this volume of POSIX.1-2017. (BSD uses *st_blocks* only when processing the −**ls** primary.)
2. Users usually think of file size in terms of bytes, which is also the unit used by the *ls* utility for the output from the −**l** option. (In both System V and BSD, *ls* uses *st_size* for the −**l** option size field and uses *st_blocks* for the *ls* −**s** calculations. This volume of POSIX.1-2017 does not specify *ls* −**s**.)

The descriptions of −**atime**, −**ctime**, and −**mtime** were changed from the SVID description of *n* ``days'' to *n* being the result of the integer division of the time difference in seconds by 86 400. The description is also different in terms of the exact timeframe for the *n* case (*versus* the +*n* or −*n*), but it matches all known historical implementations. It refers to one 86 400 second period in the past, not any time from the beginning of that period to the current time. For example, −**atime** 2 is true if the file was accessed any time in the period from 72 hours to 48 hours ago.

Historical implementations do not modify "{}" when it appears as a substring of an −**exec** or −**ok** *utility_name* or argument string. There have been numerous user requests for this extension, so this volume of POSIX.1-2017 allows the desired behavior. At least one recent implementation does support this feature, but encountered several problems in managing memory allocation and dealing with multiple occurrences of "{}" in a string while it was being developed, so it is not yet required behavior.

Assuming the presence of −**print** was added to correct a historical pitfall that plagues novice users, it is entirely upwards-compatible from the historical System V *find* utility. In its simplest form (*find directory*), it could be confused with the historical BSD fast *find*. The BSD developers agreed that adding −**print** as a default expression was the correct decision and have added the fast *find* functionality within a new utility called *locate*.

Historically, the −**L** option was implemented using the primary −**follow**. The −**H** and −**L** options were added for two reasons. First, they offer a finer granularity of control and consistency with other programs that walk file hierarchies. Second, the −**follow** primary always evaluated to true. As they were historically really global variables that took effect before the traversal began, some valid expressions had unexpected results. An example is the expression −**print** −**o** −**follow**. Because −**print** always evaluates to true, the standard order of evaluation implies that −**follow** would never be evaluated. This was never the case. Historical practice for the −**follow** primary,

however, is not consistent. Some implementations always follow symbolic links on the command line whether –**follow** is specified or not. Others follow symbolic links on the command line only if –**follow** is specified. Both behaviors are provided by the –**H** and –**L** options, but scripts using the current –**follow** primary would be broken if the –**follow** option is specified to work either way.

Since the –**L** option resolves all symbolic links and the –**type** *l* primary is true for symbolic links that still exist after symbolic links have been resolved, the command:

```
find –L . –type l
```

prints a list of symbolic links reachable from the current directory that do not resolve to accessible files.

A feature of SVR4's *find* utility was the –**exec** primary's **+** terminator. This allowed filenames containing special characters (especially <newline> characters) to be grouped together without the problems that occur if such filenames are piped to *xargs*. Other implementations have added other ways to get around this problem, notably a –**print0** primary that wrote filenames with a null byte terminator. This was considered here, but not adopted. Using a null terminator meant that any utility that was going to process *find*'s –**print0** output had to add a new option to parse the null terminators it would now be reading.

The "`–exec ... {} +`" syntax adopted was a result of IEEE PASC Interpretation 1003.2 #210. It should be noted that this is an incompatible change to IEEE Std 1003.2-1992. For example, the following command printed all files with a '`–`' after their name if they are regular files, and a '`+`' otherwise:

```
find / –type f –exec echo {} – ';' –o –exec echo {} + ';'
```

The change invalidates usage like this. Even though the previous standard stated that this usage would work, in practice many did not support it and the standard developers felt it better to now state that this was not allowable.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

> The –**perm** [–]*onum* primary is supported.

The *find* utility is aligned with the IEEE P1003.2b draft standard, to include processing of symbolic links and changes to the description of the **atime**, **ctime**, and **mtime** operands.

IEEE PASC Interpretation 1003.2 #210 is applied, extending the –**exec** operand.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/13 is applied, updating the RATIONALE section to be consistent with the normative text.

Issue 7

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

Austin Group Interpretation 1003.1-2001 #127 is applied, rephrasing the description of the **−exec** primary to be ``immediately follows''.

Austin Group Interpretation 1003.1-2001 #185 is applied, clarifying the requirements for the **−H** and **−L** options.

Austin Group Interpretation 1003.1-2001 #186 is applied, clarifying the requirements for the evaluation of *path* operands.

Austin Group Interpretation 1003.1-2001 #195 is applied, clarifying the interpretation of the first operand.

SD5-XCU-ERN-48 is applied, clarifying the **−L** option in the case that the referenced file does not exist.

SD5-XCU-ERN-89 is applied, updating the OPERANDS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-117 is applied, clarifying the **−perm** operand.

SD5-XCU-ERN-122 is applied, adding a new EXAMPLE.

The description of the **−name** primary is revised and the **−path** primary is added (with a new example).

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0086 [365], XCU/TC1-2008/0087 [310], XCU/TC1-2008/0088 [309,310,430], XCU/TC1-2008/0089 [235], and XCU/TC1-2008/0090 [445] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0099 [584], XCU/TC2-2008/0100 [584], and XCU/TC2-2008/0101 [584] are applied.

92291 **NAME**

92292 fold ‡'filter for folding lines

92293 **SYNOPSIS**

92294 `fold [-bs] [-w width] [file...]`

92295 **DESCRIPTION**

92296 The *fold* utility is a filter that shall fold lines from its input files, breaking the lines to have a
92297 maximum of *width* column positions (or bytes, if the **-b** option is specified). Lines shall be
92298 broken by the insertion of a <newline> such that each output line (referred to later in this section
92299 as a *segment*) is the maximum width possible that does not exceed the specified number of
92300 column positions (or bytes). A line shall not be broken in the middle of a character. The behavior
92301 is undefined if *width* is less than the number of columns any single character in the input would
92302 occupy.

92303 If the <carriage-return>, <backspace>, or <tab> characters are encountered in the input, and the
92304 **-b** option is not specified, they shall be treated specially:

92305 <backspace> The current count of line width shall be decremented by one, although the count
92306 never shall become negative. The *fold* utility shall not insert a <newline>
92307 immediately before or after any <backspace>, unless the following character has a
92308 width greater than 1 and would cause the line width to exceed *width*.

92309 <carriage-return>
92310 The current count of line width shall be set to zero. The *fold* utility shall not insert a
92311 <newline> immediately before or after any <carriage-return>.

92312 <tab> Each <tab> encountered shall advance the column position pointer to the next tab
92313 stop. Tab stops shall be at each column position *n* such that *n* modulo 8 equals 1.

92314 **OPTIONS**

92315 The *fold* utility shall conform to XBD Section 12.2 (on page 216).

92316 The following options shall be supported:

92317 **-b** Count *width* in bytes rather than column positions.

92318 **-s** If a segment of a line contains a <blank> within the first *width* column positions (or
92319 bytes), break the line after the last such <blank> meeting the width constraints. If
92320 there is no <blank> meeting the requirements, the **-s** option shall have no effect for
92321 that output segment of the input line.

92322 **-w** *width* Specify the maximum line length, in column positions (or bytes if **-b** is specified).
92323 The results are unspecified if *width* is not a positive decimal number. The default
92324 value shall be 80.

92325 **OPERANDS**

92326 The following operand shall be supported:

92327 *file* A pathname of a text file to be folded. If no *file* operands are specified, the standard
92328 input shall be used.

92329 **STDIN**

92330 The standard input shall be used if no *file* operands are specified, and shall be used if a *file*
92331 operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise,
92332 the standard input shall not be used. See the INPUT FILES section.

92333 **INPUT FILES**

92334 If the **–b** option is specified, the input files shall be text files except that the lines are not limited
92335 to {LINE_MAX} bytes in length. If the **–b** option is not specified, the input files shall be text files.

92336 **ENVIRONMENT VARIABLES**

92337 The following environment variables shall affect the execution of *fold*:

92338 *LANG* Provide a default value for the internationalization variables that are unset or null.
92339 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
92340 variables used to determine the values of locale categories.)

92341 *LC_ALL* If set to a non-empty string value, override the values of all the other
92342 internationalization variables.

92343 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
92344 characters (for example, single-byte as opposed to multi-byte characters in
92345 arguments and input files), and for the determination of the width in column
92346 positions each character would occupy on a constant-width font output device.

92347 *LC_MESSAGES*
92348 Determine the locale that should be used to affect the format and contents of
92349 diagnostic messages written to standard error.

92350 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92351 **ASYNCHRONOUS EVENTS**

92352 Default.

92353 **STDOUT**

92354 The standard output shall be a file containing a sequence of characters whose order shall be
92355 preserved from the input files, possibly with inserted <newline> characters.

92356 **STDERR**

92357 The standard error shall be used only for diagnostic messages.

92358 **OUTPUT FILES**

92359 None.

92360 **EXTENDED DESCRIPTION**

92361 None.

92362 **EXIT STATUS**

92363 The following exit values shall be returned:

92364 0 All input files were processed successfully.

92365 >0 An error occurred.

92366 **CONSEQUENCES OF ERRORS**

92367 Default.

92368 **APPLICATION USAGE**

92369 The *cut* and *fold* utilities can be used to create text files out of files with arbitrary line lengths.
92370 The *cut* utility should be used when the number of lines (or records) needs to remain constant.
92371 The *fold* utility should be used when the contents of long lines need to be kept contiguous.

92372 The *fold* utility is frequently used to send text files to printers that truncate, rather than fold, lines
92373 wider than the printer is able to print (usually 80 or 132 column positions).

92374 **EXAMPLES**

92375 An example invocation that submits a file of possibly long lines to the printer (under the
92376 assumption that the user knows the line width of the printer to be assigned by *lp*):

92377 ```
fold -w 132 bigfile | lp
```

92378 **RATIONALE**

92379 Although terminal input in canonical processing mode requires the erase character (frequently
92380 set to <backspace>) to erase the previous character (not byte or column position), terminal
92381 output is not buffered and is extremely difficult, if not impossible, to parse correctly; the
92382 interpretation depends entirely on the physical device that actually displays/prints/stores the
92383 output. In all known internationalized implementations, the utilities producing output for
92384 mixed column-width output assume that a <backspace> character backs up one column position
92385 and outputs enough <backspace> characters to return to the start of the character when
92386 <backspace> is used to provide local line motions to support underlining and emboldening
92387 operations. Since *fold* without the **–b** option is dealing with these same constraints, <backspace>
92388 is always treated as backing up one column position rather than backing up one character.

92389 Historical versions of the *fold* utility assumed 1 byte was one character and occupied one column
92390 position when written out. This is no longer always true. Since the most common usage of *fold* is
92391 believed to be folding long lines for output to limited-length output devices, this capability was
92392 preserved as the default case. The **–b** option was added so that applications could *fold* files with
92393 arbitrary length lines into text files that could then be processed by the standard utilities. Note
92394 that although the width for the **–b** option is in bytes, a line is never split in the middle of a
92395 character. (It is unspecified what happens if a width is specified that is too small to hold a single
92396 character found in the input followed by a <newline>.)

92397 The tab stops are hardcoded to be every eighth column to meet historical practice. No new
92398 method of specifying other tab stops was invented.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

fort77 — FORTRAN compiler (**FORTRAN**)

SYNOPSIS

OB FD

```
fort77 [−c] [−g] [−L directory]... [−O optlevel] [−o outfile] [−s]
    [−w] operand...
```

DESCRIPTION

The *fort77* utility is the interface to the FORTRAN compilation system; it shall accept the full FORTRAN-77 language defined by the ANSI X3.9-1978 standard. The system conceptually consists of a compiler and link editor. The files referenced by *operand*s are compiled and linked to produce an executable file. It is unspecified whether the linking occurs entirely within the operation of *fort77*; some implementations may produce objects that are not fully resolved until the file is executed.

If the **−c** option is present, for all pathname operands of the form *file***.f**, the files:

```
$(basename pathname.f).o
```

shall be created or overwritten as the result of successful compilation. If the **−c** option is not specified, it is unspecified whether such **.o** files are created or deleted for the *file***.f** operands.

If there are no options that prevent link editing (such as **−c**) and all operands compile and link without error, the resulting executable file shall be written into the file named by the **−o** option (if present) or to the file **a.out**. The executable file shall be created as specified in the System Interfaces volume of POSIX.1-2017, except that the file permissions shall be set to:

S_IRWXO | S_IRWXG | S_IRWXU

and that the bits specified by the *umask* of the process shall be cleared.

OPTIONS

The *fort77* utility shall conform to XBD Section 12.2 (on page 216), except that:

The **−l** *library* operands have the format of options, but their position within a list of operands affects the order in which libraries are searched.

The order of specifying the multiple **−L** options is significant.

Conforming applications shall specify each option separately; that is, grouping option letters (for example, **−cg**) need not be recognized by all implementations.

The following options shall be supported:

−c Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.

−g Produce symbolic information in the object or executable files; the nature of this information is unspecified, and may be modified by implementation-defined interactions with other options.

−s Produce object or executable files, or both, from which symbolic and other information not required for proper execution using the *exec* family of functions defined in the System Interfaces volume of POSIX.1-2017 has been removed (stripped). If both **−g** and **−s** options are present, the action taken is unspecified.

−o *outfile* Use the pathname *outfile*, instead of the default **a.out**, for the executable file produced. If the **−o** option is present with **−c**, the result is unspecified.

92454 **−L** *directory* Change the algorithm of searching for the libraries named in **−l** operands to look in
92455 the directory named by the *directory* pathname before looking in the usual places.
92456 Directories named in **−L** options shall be searched in the specified order. At least
92457 ten instances of this option shall be supported in a single *fort77* command
92458 invocation. If a directory specified by a **−L** option contains a file named **libf.a**, the
92459 results are unspecified.

92460 **−O** *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit
92461 `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the
92462 nature of the optimization is unspecified. If the **−O** option is omitted, the nature of
92463 the system's default optimization is unspecified. It is unspecified whether code
92464 generated in the presence of the **−O** 0 option is the same as that generated when
92465 **−O** is omitted. Other *optlevel* values may be supported.

92466 **−w** Suppress warnings.

92467 Multiple instances of **−L** options can be specified.

92468 **OPERANDS**

92469 An *operand* is either in the form of a pathname or the form **−l** *library*. At least one operand of the
92470 pathname form shall be specified. The following operands shall be supported:

92471 *file*.**f** The pathname of a FORTRAN source file to be compiled and optionally passed to
92472 the link editor. The filename operand shall be of this form if the **−c** option is used.

92473 *file*.**a** A library of object files typically produced by *ar*, and passed directly to the link
92474 editor. Implementations may recognize implementation-defined suffixes other
92475 than **.a** as denoting object file libraries.

92476 *file*.**o** An object file produced by *fort77* **−c** and passed directly to the link editor.
92477 Implementations may recognize implementation-defined suffixes other than **.o** as
92478 denoting object files.

92479 The processing of other files is implementation-defined.

92480 **−l** *library* (The letter ell.) Search the library named:

92481 `lib`*`library`*`.a`

92482 A library is searched when its name is encountered, so the placement of a **−l**
92483 operand is significant. Several standard libraries can be specified in this manner, as
92484 described in the EXTENDED DESCRIPTION section. Implementations may
92485 recognize implementation-defined suffixes other than **.a** as denoting libraries.

92486 **STDIN**

92487 Not used.

92488 **INPUT FILES**

92489 The input file shall be one of the following: a text file containing FORTRAN source code; an
92490 object file in the format produced by *fort77* **−c**; or a library of object files, in the format produced
92491 by archiving zero or more object files, using *ar*. Implementations may supply additional utilities
92492 that produce files in these formats. Additional input files are implementation-defined.

92493 A <tab> encountered within the first six characters on a line of source code shall cause the
92494 compiler to interpret the following character as if it were the seventh character on the line (that
92495 is, in column 7).

92496 **ENVIRONMENT VARIABLES**

92497 The following environment variables shall affect the execution of *fort77*:

92498 92499 92500 *LANG* Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

92501 92502 *LC_ALL* If set to a non-empty string value, override the values of all the other internationalization variables.

92503 92504 92505 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

92506 92507 92508 *LC_MESSAGES* Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

92509 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92510 92511 *TMPDIR* Determine the pathname that should override the default directory for temporary files, if any.

92512 **ASYNCHRONOUS EVENTS**

92513 Default.

92514 **STDOUT**

92515 Not used.

92516 **STDERR**

92517 92518 The standard error shall be used only for diagnostic messages. If more than one *file* operand ending in **.f** (or possibly other unspecified suffixes) is given, for each such file:

92519 `"%s:\n", <file>`

92520 may be written to allow identification of the diagnostic message with the appropriate input file.

92521 92522 This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

92523 **OUTPUT FILES**

92524 Object files, listing files, and executable files shall be produced in unspecified formats.

92525 **EXTENDED DESCRIPTION**

92526 **Standard Libraries**

92527 The *fort77* utility shall recognize the following **–l** operand for the standard library:

92528 92529 **–l f** This library contains all functions referenced in the ANSI X3.9-1978 standard. This operand shall not be required to be present to cause a search of this library.

92530 92531 92532 In the absence of options that inhibit invocation of the link editor, such as **–c**, the *fort77* utility shall cause the equivalent of a **–l f** operand to be passed to the link editor as the last **–l** operand, causing it to be searched after all other object files and libraries are loaded.

92533 92534 It is unspecified whether the library **libf.a** exists as a regular file. The implementation may accept as **–l** operands names of objects that do not exist as regular files.

92535 **External Symbols**

92536 The FORTRAN compiler and link editor shall support the significance of external symbols up to
92537 a length of at least 31 bytes; case folding is permitted. The action taken upon encountering
92538 symbols exceeding the implementation-defined maximum symbol length is unspecified.

92539 The compiler and link editor shall support a minimum of 511 external symbols per source or
92540 object file, and a minimum of 4 095 external symbols total. A diagnostic message is written to
92541 standard output if the implementation-defined limit is exceeded; other actions are unspecified.

92542 **EXIT STATUS**

92543 The following exit values shall be returned:

92544 0 Successful compilation or link edit.

92545 >0 An error occurred.

92546 **CONSEQUENCES OF ERRORS**

92547 When *fort77* encounters a compilation error, it shall write a diagnostic to standard error and
92548 continue to compile other source code operands. It shall return a non-zero exit status, but it is
92549 implementation-defined whether an object module is created. If the link edit is unsuccessful, a
92550 diagnostic message shall be written to standard error, and *fort77* shall exit with a non-zero status.

92551 **APPLICATION USAGE**

92552 None.

92553 **EXAMPLES**

92554 The following usage example compiles **xyz.f** and creates the executable file **foo**:

92555 `fort77 -o foo xyz.f`

92556 The following example compiles **xyz.f** and creates the object file **xyz.o**:

92557 `fort77 -c xyz.f`

92558 The following example compiles **xyz.f** and creates the executable file **a.out**:

92559 `fort77 xyz.f`

92560 The following example compiles **xyz.f**, links it with **b.o**, and creates the executable **a.out**:

92561 `fort77 xyz.f b.o`

92562 **RATIONALE**

92563 The name of this utility was chosen as *fort77* to parallel the renaming of the C compiler. The
92564 name *f77* was not chosen to avoid problems with historical implementations. The
92565 ANSI X3.9-1978 standard was selected as a normative reference because the ISO/IEC version of
92566 FORTRAN-77 has been superseded by the ISO/IEC 1539:1991 standard.

92567 The file inclusion and symbol definition **#define** mechanisms used by the *c99* utility were not
92568 included in this volume of POSIX.1-2017 ‡even though they are commonly implemented ‡since
92569 there is no requirement that the FORTRAN compiler use the C preprocessor.

92570 The **-onetrip** option was not included in this volume of POSIX.1-2017, even though many
92571 historical compilers support it, because it is derived from FORTRAN-66; it is an anachronism
92572 that should not be perpetuated.

92573 Some implementations produce compilation listings. This aspect of FORTRAN has been left
92574 unspecified because there was controversy concerning the various methods proposed for
92575 implementing it: a **-V** option overlapped with historical vendor practice and a naming
92576 convention of creating files with **.l** suffixes collided with historical *lex* file naming practice.

There is no **−I** option in this version of this volume of POSIX.1-2017 to specify a directory for file inclusion. An INCLUDE directive has been a part of the Fortran-90 discussions, but an interface supporting that standard is not in the current scope.

It is noted that many FORTRAN compilers produce an object module even when compilation errors occur; during a subsequent compilation, the compiler may patch the object module rather than recompiling all the code. Consequently, it is left to the implementor whether or not an object file is created.

A reference to MIL-STD-1753 was removed from an early proposal in response to a request from the POSIX FORTRAN-binding standard developers. It was not the intention of the standard developers to require certification of the FORTRAN compiler, and IEEE Std 1003.9-1992 does not specify the military standard or any special preprocessing requirements. Furthermore, use of that document would have been inappropriate for an international standard.

The specification of optimization has been subject to changes through early proposals. At one time, **−O** and **−N** were Booleans: optimize and do not optimize (with an unspecified default). Some historical practice led this to be changed to:

−O 0 No optimization.

−O 1 Some level of optimization.

−O *n* Other, unspecified levels of optimization.

It is not always clear whether ``good code generation'' is the same thing as optimization. Simple optimizations of local actions do not usually affect the semantics of a program. The **−O** 0 option has been included to accommodate the very particular nature of scientific calculations in a highly optimized environment; compilers make errors. Some degree of optimization is expected, even if it is not documented here, and the ability to shut it off completely could be important when porting an application. An implementation may treat **−O** 0 as ``do less than normal'' if it wishes, but this is only meaningful if any of the operations it performs can affect the semantics of a program. It is highly dependent on the implementation whether doing less than normal is logical. It is not the intent of the **−O** 0 option to ask for inefficient code generation, but rather to assure that any semantically visible optimization is suppressed.

The specification of standard library access is consistent with the C compiler specification. Implementations are not required to have **/usr/lib/libf.a**, as many historical implementations do, but if not they are required to recognize **f** as a token.

External symbol size limits are in normative text; conforming applications need to know these limits. However, the minimum maximum symbol length should be taken as a constraint on a conforming application, not on an implementation, and consequently the action taken for a symbol exceeding the limit is unspecified. The minimum size for the external symbol table was added for similar reasons.

The CONSEQUENCES OF ERRORS section clearly specifies the behavior of the compiler when compilation or link-edit errors occur. The behavior of several historical implementations was examined, and the choice was made to be silent on the status of the executable, or **a.out**, file in the face of compiler or linker errors. If a linker writes the executable file, then links it on disk with *lseek*( )s and *write*( )s, the partially linked executable file can be left on disk and its execute bits turned off if the link edit fails. However, if the linker links the image in memory before writing the file to disk, it need not touch the executable file (if it already exists) because the link edit fails. Since both approaches are historical practice, a conforming application shall rely on the exit status of *fort77*, rather than on the existence or mode of the executable file.

The **−g** and **−s** options are not specified as mutually-exclusive. Historically, these two options

have been mutually-exclusive, but because both are so loosely specified, it seemed appropriate to leave their interaction unspecified.

The requirement that conforming applications specify compiler options separately is to reserve the multi-character option name space for vendor-specific compiler options, which are known to exist in many historical implementations. Implementations are not required to recognize, for example, **–gc** as if it were **–g –c**; nor are they forbidden from doing so. The SYNOPSIS shows all of the options separately to highlight this requirement on applications.

Echoing filenames to standard error is considered a diagnostic message because it would otherwise be difficult to associate an error message with the erring file. They are described with ``may'' to allow implementations to use other methods of identifying files and to parallel the description in *c99*.

FUTURE DIRECTIONS

Future versions of this standard may withdraw this utility. There are implementations of compilers that conform to much more recent versions of the FORTRAN programming language. Since there is no active FORTRAN binding to POSIX.1-2017, this standard does not need to specify any compiler.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the FORTRAN Development Utilities option.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0102 [546] and XCU/TC2-2008/0103 [546] are applied.

92652 **NAME**

92653 fuser — list process IDs of all processes that have one or more files open

92654 **SYNOPSIS**

92655 XSI `fuser [-cfu] file...`

92656 **DESCRIPTION**

92657 The *fuser* utility shall write to standard output the process IDs of processes running on the local
92658 system that have one or more named files open. For block special devices, all processes using
92659 any file on that device are listed.

92660 The *fuser* utility shall write to standard error additional information about the named files
92661 indicating how the file is being used.

92662 Any output for processes running on remote systems that have a named file open is unspecified.

92663 A user may need appropriate privileges to invoke the *fuser* utility.

92664 **OPTIONS**

92665 The *fuser* utility shall conform to XBD Section 12.2 (on page 216).

92666 The following options shall be supported:

92667 **-c** The file is treated as a mount point and the utility shall report on any files open in
92668 the file system.

92669 **-f** The report shall be only for the named files.

92670 **-u** The user name, in parentheses, associated with each process ID written to standard
92671 output shall be written to standard error.

92672 **OPERANDS**

92673 The following operand shall be supported:

92674 *file* A pathname on which the file or file system is to be reported.

92675 **STDIN**

92676 Not used.

92677 **INPUT FILES**

92678 The user database.

92679 **ENVIRONMENT VARIABLES**

92680 The following environment variables shall affect the execution of *fuser*:

92681 *LANG* Provide a default value for the internationalization variables that are unset or null.
92682 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
92683 variables used to determine the values of locale categories.)

92684 *LC_ALL* If set to a non-empty string value, override the values of all the other
92685 internationalization variables.

92686 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
92687 characters (for example, single-byte as opposed to multi-byte characters in
92688 arguments).

92689 *LC_MESSAGES*
92690 Determine the locale that should be used to affect the format and contents of
92691 diagnostic messages written to standard error.

92692 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92693 **ASYNCHRONOUS EVENTS**

92694 Default.

92695 **STDOUT**

92696 The *fuser* utility shall write the process ID for each process using each file given as an operand to
92697 standard output in the following format:

92698 `"%d", <process_id>`

92699 **STDERR**

92700 The *fuser* utility shall write diagnostic messages to standard error.

92701 The *fuser* utility also shall write the following to standard error:

92702 The pathname of each named file is written followed immediately by a <colon>.

92703 For each process ID written to standard output, the character `'c'` shall be written to
92704 standard error if the process is using the file as its current directory and the character `'r'`
92705 shall be written to standard error if the process is using the file as its root directory.
92706 Implementations may write other alphabetic characters to indicate other uses of files.

92707 When the **−u** option is specified, characters indicating the use of the file shall be followed
92708 immediately by the user name, in parentheses, corresponding to the real user ID of the
92709 process. If the user name cannot be resolved from the real user ID of the process, the real
92710 user ID of the process shall be written instead of the user name.

92711 When standard output and standard error are directed to the same file, the output shall be
92712 interleaved so that the filename appears at the start of each line, followed by the process ID and
92713 characters indicating the use of the file. Then, if the **−u** option is specified, the user name or user
92714 ID for each process using that file shall be written.

92715 A <newline> shall be written to standard error after the last output described above for each *file*
92716 operand.

92717 **OUTPUT FILES**

92718 None.

92719 **EXTENDED DESCRIPTION**

92720 None.

92721 **EXIT STATUS**

92722 The following exit values shall be returned:

92723 0 Successful completion.

92724 >0 An error occurred.

92725 **CONSEQUENCES OF ERRORS**

92726 Default.

92727 **APPLICATION USAGE**

92728 None.

92729 **EXAMPLES**

92730 The command:

92731 `fuser −fu .`

92732 writes to standard output the process IDs of processes that are using the current directory and
92733 writes to standard error an indication of how those processes are using the directory and the
92734 user names associated with the processes that are using the current directory.

92735 `fuser −c <mount point>`

92736 writes to standard output the process IDs of processes that are using any file in the file system
92737 which is mounted on <*mount point*> and writes to standard error an indication of how those
92738 processes are using the files.

92739 `fuser <mount point>`

92740 writes to standard output the process IDs of processes that are using the file which is named by
92741 <*mount point*> and writes to standard error an indication of how those processes are using the
92742 file.

92743 `fuser <block device>`

92744 writes to standard output the process IDs of processes that are using any file which is on the
92745 device named by <*block device*> and writes to standard error an indication of how those
92746 processes are using the file.

92747 `fuser −f <block device>`

92748 writes to standard output the process IDs of processes that are using the file <*block device*> itself
92749 and writes to standard error an indication of how those processes are using the file.

92750 **RATIONALE**

92751 The definition of the *fuser* utility follows existing practice.

92752 **FUTURE DIRECTIONS**

92753 None.

92754 **SEE ALSO**

92755 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

92756 **CHANGE HISTORY**

92757 First released in Issue 5.

92758 **Issue 7**

92759 SD5-XCU-ERN-90 is applied, updating the EXAMPLES section.

92760 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

92761 **NAME**

92762 gencat ‡'generate a formatted message catalog

92763 **SYNOPSIS**

92764 `gencat` *catfile msgfile*`...`

92765 **DESCRIPTION**

92766 The *gencat* utility shall merge the message text source file *msgfile* into a formatted message
92767 catalog *catfile*. The file *catfile* shall be created if it does not already exist. If *catfile* does exist, its
92768 messages shall be included in the new *catfile*. If set and message numbers collide, the new
92769 message text defined in *msgfile* shall replace the old message text currently contained in *catfile*.

92770 **OPTIONS**

92771 None.

92772 **OPERANDS**

92773 The following operands shall be supported:

92774 *catfile* A pathname of the formatted message catalog. If `'−'` is specified, standard output
92775 shall be used. The format of the message catalog produced is unspecified.

92776 *msgfile* A pathname of a message text source file. If `'−'` is specified for an instance of
92777 *msgfile*, standard input shall be used. The format of message text source files is
92778 defined in the EXTENDED DESCRIPTION section.

92779 **STDIN**

92780 The standard input shall not be used unless a *msgfile* operand is specified as `'−'`.

92781 **INPUT FILES**

92782 The input files shall be text files.

92783 **ENVIRONMENT VARIABLES**

92784 The following environment variables shall affect the execution of *gencat*:

92785 *LANG* Provide a default value for the internationalization variables that are unset or null.
92786 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
92787 variables used to determine the values of locale categories.)

92788 *LC_ALL* If set to a non-empty string value, override the values of all the other
92789 internationalization variables.

92790 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
92791 characters (for example, single-byte as opposed to multi-byte characters in
92792 arguments and input files).

92793 *LC_MESSAGES*

92794 Determine the locale that should be used to affect the format and contents of
92795 diagnostic messages written to standard error.

92796 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92797 **ASYNCHRONOUS EVENTS**

92798 Default.

92799 **STDOUT**

92800 The standard output shall not be used unless the *catfile* operand is specified as `'−'`.

92801 **STDERR**

92802 The standard error shall be used only for diagnostic messages.

92803 **OUTPUT FILES**

92804 None.

92805 **EXTENDED DESCRIPTION**

92806 The content of a message text file shall be in the format defined as follows. Note that the fields of
92807 a message text source line are separated by a single <blank> character. Any other <blank>
92808 characters are considered to be part of the subsequent field.

92809 **$set** *n comment*

92810 This line specifies the set identifier of the following messages until the next **$set** or
92811 end-of-file appears. The *n* denotes the set identifier, which is defined as a number
92812 in the range [1, {NL_SETMAX}] (see the **<limits.h>** header defined in the Base
92813 Definitions volume of POSIX.1-2017). The application shall ensure that set
92814 identifiers are presented in ascending order within a single source file, but need
92815 not be contiguous. Any string following the set identifier shall be treated as a
92816 comment. If no **$set** directive is specified in a message text source file, all messages
92817 shall be located in an implementation-defined default message set NL_SETD (see
92818 the **<nl_types.h>** header defined in the Base Definitions volume of POSIX.1-2017).

92819 **$delset** *n comment*

92820 This line deletes message set *n* from an existing message catalog. The *n* denotes the
92821 set number [1, {NL_SETMAX}]. Any string following the set number shall be
92822 treated as a comment.

92823 **$** *comment* A line beginning with `'$'` followed by a <blank> shall be treated as a comment.

92824 *m message-text*

92825 The *m* denotes the message identifier, which is defined as a number in the range [1,
92826 {NL_MSGMAX}] (see the **<limits.h>** header). The *message-text* shall be stored in the
92827 message catalog with the set identifier specified by the last **$set** directive, and with
92828 message identifier *m*. If the *message-text* is empty, and a <blank> field separator is
92829 present, an empty string shall be stored in the message catalog. If a message source
92830 line has a message number, but neither a field separator nor *message-text*, the
92831 existing message with that number (if any) shall be deleted from the catalog. The
92832 application shall ensure that message identifiers are in ascending order within a
92833 single set, but need not be contiguous. The application shall ensure that the length
92834 of *message-text* is in the range [0, {NL_TEXTMAX}] (see the **<limits.h>** header).

92835 **$quote** *n* This line specifies an optional quote character *c*, which can be used to surround
92836 *message-text* so that trailing <space> characters or null (empty) messages are visible
92837 in a message source line. By default, or if an empty **$quote** directive is supplied, no
92838 quoting of *message-text* shall be recognized.

92839 Empty lines in a message text source file shall be ignored. The effects of lines starting with any
92840 character other than those defined above are implementation-defined.

92841 Text strings can contain the special characters and escape sequences defined in the following
92842 table:

Description	Symbol	Sequence
<newline>	NL(LF)	`\n`
Horizontal-tab	HT	`\t`
<vertical-tab>	VT	`\v`
<backspace>	BS	`\b`
<carriage-return>	CR	`\r`
<form-feed>	FF	`\f`
Backslash	`\`	`\\`
Bit pattern	`ddd`	`\ddd`

The escape sequence "`\ddd`" consists of <backslash> followed by one, two, or three octal digits, which shall be taken to specify the value of the desired character. If the character following a <backslash> is not one of those specified, the <backslash> shall be ignored.

A <backslash> followed by a <newline> is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

```
1 This line continues \
to the next line
```

which shall be equivalent to:

```
1 This line continues to the next line
```

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Message catalogs produced by *gencat* are binary encoded, meaning that their portability cannot be guaranteed between different types of machine. Thus, just as C programs need to be recompiled for each type of machine, so message catalogs must be recreated via *gencat*.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

XBD Chapter 8 (on page 173), **<limits.h>**, **<nl_types.h>**

CHANGE HISTORY

First released in Issue 3.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

92884 **Issue 7**

92885 The *gencat* utility is moved from the XSI option to the Base.

92886 **NAME**

92887 get ‡'get a version of an SCCS file (**DEVELOPMENT**)

92888 **SYNOPSIS**

92889 XSI `get [-begkmnlLpst] [-c cutoff] [-i list] [-r SID] [-x list] file...`

92890 **DESCRIPTION**

92891 The *get* utility shall generate a text file from each named SCCS *file* according to the specifications
92892 given by its options.

92893 The generated text shall normally be written into a file called the **g-file** whose name is derived
92894 from the SCCS filename by simply removing the leading `"s."`.

92895 **OPTIONS**

92896 The *get* utility shall conform to XBD Section 12.2 (on page 216).

92897 The following options shall be supported:

92898 **-r** *SID* Indicate the SCCS Identification String (SID) of the version (delta) of an SCCS file
92899 to be retrieved. The table shows, for the most useful cases, what version of an
92900 SCCS file is retrieved (as well as the SID of the version to be eventually created by
92901 *delta* if the **-e** option is also used), as a function of the SID specified.

92902 **-c** *cutoff* Indicate the *cutoff* date-time, in the form:

92903 *YY*[*MM*[*DD*[*HH*[*MM*[*SS*]]]]]

92904 For the *YY* component, values in the range [69,99] shall refer to years 1969 to 1999
92905 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive.

92906 **Note:** It is expected that in a future version of this standard the default century inferred
92907 from a 2-digit year will change. (This would apply to all commands accepting a
92908 2-digit year as input.)

92909 No changes (deltas) to the SCCS file that were created after the specified *cutoff*
92910 date-time shall be included in the generated text file. Units omitted from the date-
92911 time default to their maximum possible values; for example, **-c** 7502 is equivalent
92912 to **-c** 750228235959.

92913 Any number of non-numeric characters may separate the various 2-digit pieces of
92914 the *cutoff* date-time. This feature allows the user to specify a *cutoff* date in the form:
92915 **-c** "77/2/2 9:22:25".

92916 **-e** Indicate that the *get* is for the purpose of editing or making a change (delta) to the
92917 SCCS file via a subsequent use of *delta*. The **-e** option used in a *get* for a particular
92918 version (SID) of the SCCS file shall prevent further *get* commands from editing on
92919 the same SID until *delta* is executed or the **j** (joint edit) flag is set in the SCCS file.
92920 Concurrent use of *get* **-e** for different SIDs is always allowed.

92921 If the **g-file** generated by *get* with a **-e** option is accidentally ruined in the process
92922 of editing, it may be regenerated by re-executing the *get* command with the **-k**
92923 option in place of the **-e** option.

92924 SCCS file protection specified via the ceiling, floor, and authorized user list stored
92925 in the SCCS file shall be enforced when the **-e** option is used.

92926 **-b** Use with the **-e** option to indicate that the new delta should have an SID in a new
92927 branch as shown in the table below. This option shall be ignored if the **b** flag is not
92928 present in the file or if the retrieved delta is not a leaf delta. (A leaf delta is one that
92929 has no successors on the SCCS file tree.)

Note: A branch delta may always be created from a non-leaf delta.

−i *list* Indicate a *list* of deltas to be included (forced to be applied) in the creation of the generated file. The *list* has the following syntax:

```
<list> ::= <range> | <list> , <range>
<range> ::= SID | SID − SID
```

SID, the SCCS Identification of a delta, may be in any form shown in the ``SID Specified'' column of the table in the EXTENDED DESCRIPTION section, except that the result of supplying a partial SID is unspecified. A diagnostic message shall be written if the first SID in the range is not an ancestor of the second SID in the range.

−x *list* Indicate a *list* of deltas to be excluded (forced not to be applied) in the creation of the generated file. See the **−i** option for the *list* format.

−k Suppress replacement of identification keywords (see below) in the retrieved text by their value. The **−k** option shall be implied by the **−e** option.

−l Write a delta summary into an **l-file**.

−L Write a delta summary to standard output. All informative output that normally is written to standard output shall be written to standard error instead, unless the **−s** option is used, in which case it shall be suppressed.

−p Write the text retrieved from the SCCS file to the standard output. No **g-file** shall be created. All informative output that normally goes to the standard output shall go to standard error instead, unless the **−s** option is used, in which case it shall disappear.

−s Suppress all informative output normally written to standard output. However, fatal error messages (which shall always be written to the standard error) shall remain unaffected.

−m Precede each text line retrieved from the SCCS file by the SID of the delta that inserted the text line in the SCCS file. The format shall be:

```
"%s\t%s", <SID>, <text line>
```

−n Precede each generated text line with the %**M**% identification keyword value (see below). The format shall be:

```
"%s\t%s", <%M% value>, <text line>
```

When both the **−m** and **−n** options are used, the <*text line*> shall be replaced by the **−m** option-generated format.

−g Suppress the actual retrieval of text from the SCCS file. It is primarily used to generate an **l-file**, or to verify the existence of a particular SID.

−t Use to access the most recently created (top) delta in a given release (for example, **−r 1**), or release and level (for example, **−r 1.2**).

92967 **OPERANDS**

92968 The following operands shall be supported:

92969 *file* A pathname of an existing SCCS file or a directory. If *file* is a directory, the *get*
92970 utility shall behave as though each file in the directory were specified as a named
92971 file, except that non-SCCS files (last component of the pathname does not begin
92972 with **s.**) and unreadable files shall be silently ignored.

92973 If exactly one *file* operand appears, and it is `'-'`, the standard input shall be read;
92974 each line of the standard input is taken to be the name of an SCCS file to be
92975 processed. Non-SCCS files and unreadable files shall be silently ignored.

92976 **STDIN**

92977 The standard input shall be a text file used only if the *file* operand is specified as `'-'`. Each line
92978 of the text file shall be interpreted as an SCCS pathname.

92979 **INPUT FILES**

92980 The SCCS files shall be files of an unspecified format.

92981 **ENVIRONMENT VARIABLES**

92982 The following environment variables shall affect the execution of *get*:

92983 *LANG* Provide a default value for the internationalization variables that are unset or null.
92984 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
92985 variables used to determine the values of locale categories.)

92986 *LC_ALL* If set to a non-empty string value, override the values of all the other
92987 internationalization variables.

92988 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
92989 characters (for example, single-byte as opposed to multi-byte characters in
92990 arguments and input files).

92991 *LC_MESSAGES*

92992 Determine the locale that should be used to affect the format and contents of
92993 diagnostic messages written to standard error, and informative messages written
92994 to standard output (or standard error, if the **−p** option is used).

92995 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92996 *TZ* Determine the timezone in which the times and dates written in the SCCS file are
92997 evaluated. If the *TZ* variable is unset or NULL, an unspecified system default
92998 timezone is used.

92999 **ASYNCHRONOUS EVENTS**

93000 Default.

93001 **STDOUT**

93002 For each file processed, *get* shall write to standard output the SID being accessed and the
93003 number of lines retrieved from the SCCS file, in the following format:

93004 `"%s\n%d lines\n", <SID>, <number of lines>`

93005 If the **−e** option is used, the SID of the delta to be made shall appear after the SID accessed and
93006 before the number of lines generated, in the POSIX locale:

93007 `"%s\nnew delta %s\n%d lines\n", <SID accessed>,`
93008 `<SID to be made>, <number of lines>`

93009 If there is more than one named file or if a directory or standard input is named, each pathname

93010 shall be written before each of the lines shown in one of the preceding formats:

93011 `"\n%s:\n", <pathname>`

93012 If the **−L** option is used, a delta summary shall be written following the format specified below
93013 for **l-files**.

93014 If the **−i** option is used, included deltas shall be listed following the notation, in the POSIX
93015 locale:

93016 `"Included:\n"`

93017 If the **−x** option is used, excluded deltas shall be listed following the notation, in the POSIX
93018 locale:

93019 `"Excluded:\n"`

93020 If the **−p** or **−L** options are specified, the standard output shall consist of the text retrieved from
93021 the SCCS file.

93022 **STDERR**

93023 The standard error shall be used only for diagnostic messages, except if the **−p** or **−L** options are
93024 specified, it shall include all informative messages normally sent to standard output.

93025 **OUTPUT FILES**

93026 Several auxiliary files may be created by *get*. These files are known generically as the **g-file**, **l-**
93027 **file**, **p-file**, and **z-file**. The letter before the <hyphen-minus> is called the *tag*. An auxiliary
93028 filename shall be formed from the SCCS filename: the application shall ensure that the last
93029 component of all SCCS filenames is of the form **s.***module-name*; the auxiliary files shall be named
93030 by replacing the leading **s** with the tag. The **g-file** shall be an exception to this scheme: the **g-file**
93031 is named by removing the **s.** prefix. For example, for **s.xyz.c**, the auxiliary filenames would be
93032 **xyz.c**, **l.xyz.c**, **p.xyz.c**, and **z.xyz.c**, respectively.

93033 The **g-file**, which contains the generated text, shall be created in the current directory (unless the
93034 **−p** option is used). A **g-file** shall be created in all cases, whether or not any lines of text were
93035 generated by the *get*. It shall be owned by the real user. If the **−k** option is used or implied, the
93036 **g-file** shall be writable by the owner only (read-only for everyone else); otherwise, it shall be
93037 read-only. Only the real user need have write permission in the current directory.

93038 The **l-file** shall contain a table showing which deltas were applied in generating the retrieved
93039 text. The **l-file** shall be created in the current directory if the **−l** option is used; it shall be read-
93040 only and it is owned by the real user. Only the real user need have write permission in the
93041 current directory.

93042 Lines in the **l-file** shall have the following format:

93043 `"%c%c%cΔ%s\t%sΔ%s\n", <code1>, <code2>, <code3>,`
93044 `    <SID>, <date-time>, <login>`

93045 where the entries are:

93046 *<code1>* A <space> if the delta was applied; `'*'` otherwise.

93047 *<code2>* A <space> if the delta was applied or was not applied and ignored; `'*'` if the delta
93048 was not applied and was not ignored.

93049 *<code3>* A character indicating a special reason why the delta was or was not applied:

93050 **I** Included.

93051 **X** Excluded.

93052 **C** Cut off (by a −**c** option).

93053 <*date-time*> Date and time (using the format of the *date* utility's `%y/%m/%d %T` conversion
93054 specification format) of creation.

93055 <*login*> Login name of person who created *delta*.

93056 The comments and MR data shall follow on subsequent lines, indented one <tab>. A blank line
93057 shall terminate each entry.

93058 The **p-file** shall be used to pass information resulting from a *get* with a −**e** option along to *delta*.
93059 Its contents shall also be used to prevent a subsequent execution of *get* with a −**e** option for the
93060 same SID until *delta* is executed or the joint edit flag, **j**, is set in the SCCS file. The **p-file** shall be
93061 created in the directory containing the SCCS file and the application shall ensure that the
93062 effective user has write permission in that directory. It shall be writable by owner only, and
93063 owned by the effective user. Each line in the **p-file** shall have the following format:

93064 `"%sΔ%sΔ%sΔ%s%s%s\n", <g-file SID>,`
93065 `<SID of new delta>, <login-name of real user>,`
93066 `<date-time>, <i-value>, <x-value>`

93067 where <*i-value*> uses the format `" "` if no −**i** option was specified, and shall use the format:

93068 `"Δ−i%s", <−i option option-argument>`

93069 if a −**i** option was specified and <*x-value*> uses the format `" "` if no −**x** option was specified, and
93070 shall use the format:

93071 `"Δ−x%s", <−x option option-argument>`

93072 if a −**x** option was specified. There can be an arbitrary number of lines in the **p-file** at any time;
93073 no two lines shall have the same new delta SID.

93074 The **z-file** shall serve as a lock-out mechanism against simultaneous updates. Its contents shall
93075 be the binary process ID of the command (that is, *get*) that created it. The **z-file** shall be created
93076 in the directory containing the SCCS file for the duration of *get*. The same protection restrictions
93077 as those for the **p-file** shall apply for the **z-file**. The **z-file** shall be created read-only.

EXTENDED DESCRIPTION

Determination of SCCS Identification String				
SID* Specified	**–b Keyletter Used**	**Other Conditions**	**SID Retrieved**	**SID of Delta to be Created**
none	no	R defaults to mR	mR.mL	mR.(mL+1)
none	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
R	no	R > mR	mR.mL	R.1***
R	no	R = mR	mR.mL	mR.(mL+1)
R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
R	yes	R = mR	mR.mL	mR.mL.(mB+1).1
R	–	R < mR and R does not exist	hR.mL**	hR.mL.(mB+1).1
R	–	Trunk successor in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk successor	R.L	R.(L+1)
R.L	yes	No trunk successor	R.L	R.L.(mB+1).1
R.L	–	Trunk successor in release ≥ R	R.L	R.L.(mB+1).1
R.L.B	no	No branch successor	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch successor	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch successor	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch successor	R.L.B.S	R.L.(mB+1).1
R.L.B.S	–	Branch successor	R.L.B.S	R.L.(mB+1).1

* R, L, B, and S are the release, level, branch, and sequence components of the SID, respectively; m means maximum. Thus, for example, R.mL means ``the maximum level number within release R''; R.L.(mB+1).1 means ``the first sequence number on the new branch (that is, maximum branch number plus one) of level L within release R''. Note that if the SID specified is of the form R.L, R.L.B, or R.L.B.S, each of the specified components shall exist.

** hR is the highest existing release that is lower than the specified, nonexistent, release R.

*** This is used to force creation of the first delta in a new release.

The **–b** option is effective only if the **b** flag is present in the file. An entry of `'–'` means ``irrelevant''.

This case applies if the **d** (default SID) flag is not present in the file. If the **d** flag is present in the file, then the SID obtained from the **d** flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

93114 **System Date and Time**

93115 When a **g-file** is generated, the creation time of deltas in the SCCS file may be taken into
93116 account. If any of these times are apparently in the future, the behavior is unspecified.

93117 **Identification Keywords**

93118 Identifying information shall be inserted into the text retrieved from the SCCS file by replacing
93119 identification keywords with their value wherever they occur. The following keywords may be
93120 used in the text stored in an SCCS file:

93121 %**M**% Module name: either the value of the **m** flag in the file, or if absent, the name of the
93122 SCCS file with the leading **s.** removed.

93123 %**I**% SCCS identification (SID) (%**R**%.%**L**% or %**R**%.%**L**%.%**B**%.%**S**%) of the retrieved
93124 text.

93125 %**R**% Release.

93126 %**L**% Level.

93127 %**B**% Branch.

93128 %**S**% Sequence.

93129 %**D**% Current date (*YY*/*MM*/*DD*).

93130 %**H**% Current date (*MM*/*DD*/*YY*).

93131 %**T**% Current time (*HH*:*MM*:*SS*).

93132 %**E**% Date newest applied delta was created (*YY*/*MM*/*DD*).

93133 %**G**% Date newest applied delta was created (*MM*/*DD*/*YY*).

93134 %**U**% Time newest applied delta was created (*HH*:*MM*:*SS*).

93135 %**Y**% Module type: value of the **t** flag in the SCCS file.

93136 %**F**% SCCS filename.

93137 %**P**% SCCS absolute pathname.

93138 %**Q**% The value of the **q** flag in the file.

93139 %**C**% Current line number. This keyword is intended for identifying messages output by
93140 the program, such as ``this should not have happened'' type errors. It is not
93141 intended to be used on every line to provide sequence numbers.

93142 %**Z**% The four-character string `"@(#)"` recognizable by *what*.

93143 %**W**% A shorthand notation for constructing *what* strings:

93144 `%W%=%Z%%M%<tab>%I%`

93145 %**A**% Another shorthand notation for constructing *what* strings:

93146 `%A%=%Z%%Y%%M%%I%%Z%`

93147 **EXIT STATUS**

93148 The following exit values shall be returned:

93149 0 Successful completion.

93150 >0 An error occurred.

93151 **CONSEQUENCES OF ERRORS**

93152 Default.

93153 **APPLICATION USAGE**

93154 Problems can arise if the system date and time have been modified (for example, put forward
93155 and then back again, or unsynchronized clocks across a network) and can also arise when
93156 different values of the *TZ* environment variable are used.

93157 Problems of a similar nature can also arise for the operation of the *delta* utility, which compares
93158 the previous file body against the working file as part of its normal operation.

93159 **EXAMPLES**

93160 None.

93161 **RATIONALE**

93162 None.

93163 **FUTURE DIRECTIONS**

93164 None.

93165 **SEE ALSO**

93166 *admin*, *delta*, *prs*, *what*

93167 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

93168 **CHANGE HISTORY**

93169 First released in Issue 2.

93170 **Issue 5**

93171 A correction is made to the first format string in STDOUT.

93172 The interpretation of the *YY* component of the **–c** *cutoff* argument is noted.

93173 **Issue 6**

93174 The obsolescent SYNOPSIS is removed, removing the **–lp** option.

93175 The normative text is reworded to avoid use of the term ``must'' for application requirements.

93176 The Open Group Corrigendum U025/5 is applied, correcting text in the OPTIONS section.

93177 The Open Group Corrigendum U048/1 is applied.

93178 The Open Group Interpretation PIN4C.00014 is applied.

93179 The Open Group Base Resolution bwg2001-007 is applied as follows:

93180 The EXTENDED DESCRIPTION section is updated to make partial SID handling
93181 unspecified, reflecting common usage, and to clarify SID ranges.

93182 New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections
93183 regarding how the system date and time may be taken into account.

93184 The *TZ* environment variable is added to the ENVIRONMENT VARIABLES section.

93185 **Issue 7**

93186 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

93187 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0104 [584] is applied.

NAME

getconf ‡'get configuration values

SYNOPSIS

```
getconf [-v specification] system_var
getconf [-v specification] path_var pathname
```

DESCRIPTION

In the first synopsis form, the *getconf* utility shall write to the standard output the value of the variable specified by the *system_var* operand.

In the second synopsis form, the *getconf* utility shall write to the standard output the value of the variable specified by the *path_var* operand for the path specified by the *pathname* operand.

The value of each configuration variable shall be determined as if it were obtained by calling the function from which it is defined to be available by this volume of POSIX.1-2017 or by the System Interfaces volume of POSIX.1-2017 (see the OPERANDS section). The value shall reflect conditions in the current operating environment.

OPTIONS

The *getconf* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-v *specification*

Indicate a specific specification and version for which configuration variables shall be determined. If this option is not specified, the values returned correspond to an implementation default conforming compilation environment.

If the command:

```
getconf _POSIX_V7_ILP32_OFF32
```

does not write `"-1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf -v POSIX_V7_ILP32_OFF32 ...
```

determine values for configuration variables corresponding to the POSIX_V7_ILP32_OFF32 compilation environment specified in *c99*, the EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V7_ILP32_OFFBIG
```

does not write `"-1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf -v POSIX_V7_ILP32_OFFBIG ...
```

determine values for configuration variables corresponding to the POSIX_V7_ILP32_OFFBIG compilation environment specified in *c99*, the EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V7_LP64_OFF64
```

does not write `"-1\n"` or `"undefined\n"` to standard output, then commands of the form:

93229 `getconf –v POSIX_V7_LP64_OFF64 ...`

93230 determine values for configuration variables corresponding to the
93231 POSIX_V7_LP64_OFF64 compilation environment specified in *c99*, the
93232 EXTENDED DESCRIPTION.

93233 If the command:

93234 `getconf _POSIX_V7_LPBIG_OFFBIG`

93235 does not write `"–1\n"` or `"undefined\n"` to standard output, then commands of
93236 the form:

93237 `getconf –v POSIX_V7_LPBIG_OFFBIG ...`

93238 determine values for configuration variables corresponding to the
93239 POSIX_V7_LPBIG_OFFBIG compilation environment specified in *c99*, the
93240 EXTENDED DESCRIPTION.

93241 **OPERANDS**

93242 The following operands shall be supported:

93243 *path_var* A name of a configuration variable. All of the variables in the Variable column of
93244 the table in the DESCRIPTION of the *fpathconf*( ) function defined in the System
93245 Interfaces volume of POSIX.1-2017, without the enclosing braces, shall be
93246 supported. The implementation may add other local variables.

93247 *pathname* A pathname for which the variable specified by *path_var* is to be determined.

93248 *system_var* A name of a configuration variable. All of the following variables shall be
93249 supported:

93250 The names in the Variable column of the table in the DESCRIPTION of the
93251 *sysconf*( ) function in the System Interfaces volume of POSIX.1-2017, except
93252 for the entries corresponding to _SC_CLK_TCK, _SC_GETGR_R_SIZE_MAX,
93253 and _SC_GETPW_R_SIZE_MAX, without the enclosing braces.

93254 For compatibility with earlier versions, the following variable names shall
93255 also be supported:

93256 POSIX2_C_BIND
93257 POSIX2_C_DEV
93258 POSIX2_CHAR_TERM
93259 POSIX2_FORT_DEV
93260 POSIX2_FORT_RUN
93261 POSIX2_LOCALEDEF
93262 POSIX2_SW_DEV
93263 POSIX2_UPE
93264 POSIX2_VERSION

93265 and shall be equivalent to the same name prefixed with an <underscore>.
93266 This requirement may be removed in a future version.

93267 The names of the symbolic constants used as the *name* argument of the
93268 *confstr*( ) function in the System Interfaces volume of POSIX.1-2017, without
93269 the _CS_ prefix.

The names of the symbolic constants listed under the headings ``Maximum Values'' and ``Minimum Values'' in the description of the **<limits.h>** header in the Base Definitions volume of POSIX.1-2017, without the enclosing braces.

For compatibility with earlier versions, the following variable names shall also be supported:

POSIX2_BC_BASE_MAX
POSIX2_BC_DIM_MAX
POSIX2_BC_SCALE_MAX
POSIX2_BC_STRING_MAX
POSIX2_COLL_WEIGHTS_MAX
POSIX2_EXPR_NEST_MAX
POSIX2_LINE_MAX
POSIX2_RE_DUP_MAX

and shall be equivalent to the same name prefixed with an <underscore>. This requirement may be removed in a future version.

The implementation may add other local values.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getconf*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the specified variable is defined on the system and its value is described to be available from the *confstr*( ) function defined in the System Interfaces volume of POSIX.1-2017, its value shall be written in the following format:

`"%s\n", <value>`

Otherwise, if the specified variable is defined on the system, its value shall be written in the

following format:

```
"%d\n", <value>
```

If the specified variable is valid, but is undefined on the system, *getconf* shall write using the following format:

```
"undefined\n"
```

If the variable name is invalid or an error occurs, nothing shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The specified variable is valid and information about its current state was written successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The following example illustrates the value of {NGROUPS_MAX}:

```
getconf NGROUPS_MAX
```

The following example illustrates the value of {NAME_MAX} for a specific directory:

```
getconf NAME_MAX /usr
```

The following example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
    if [ "$value" = "undefined" ]; then
        echo PATH_MAX in /usr is indeterminate.
    else
        echo PATH_MAX in /usr is $value.
    fi
else
    echo Error in getconf.
fi
```

RATIONALE

The original need for this utility, and for the *confstr*() function, was to provide a way of finding the configuration-defined default value for the *PATH* environment variable. Since *PATH* can be modified by the user to include directories that could contain utilities replacing the standard utilities, shell scripts need a way to determine the system-supplied *PATH* environment variable value that contains the correct search path for the standard utilities. It was later suggested that

93355 access to the other variables described in this volume of POSIX.1-2017 could also be useful to
93356 applications.

93357 This functionality of *getconf* would not be adequately subsumed by another command such as:

93358 `grep var /etc/conf`

93359 because such a strategy would provide correct values for neither those variables that can vary at
93360 runtime, nor those that can vary depending on the path.

93361 Early proposal versions of *getconf* specified exit status 1 when the specified variable was valid,
93362 but not defined on the system. The output string `"undefined"` is now used to specify this case
93363 with exit code 0 because so many things depend on an exit code of zero when an invoked utility
93364 is successful.

93365 **FUTURE DIRECTIONS**

93366 None.

93367 **SEE ALSO**

93368 *c99*

93369 XBD Chapter 8 (on page 173), Section 12.2 (on page 216), **<limits.h>**

93370 XSH *confstr*( ), *fpathconf*( ), *sysconf*( ), *system*( )

93371 **CHANGE HISTORY**

93372 First released in Issue 4.

93373 **Issue 5**

93374 In the OPERANDS section:

93375 {NL_MAX} is changed to {NL_NMAX}.

93376 Entries beginning NL_ are deleted from the list of standard configuration variables.

93377 The list of variables previously marked UX is merged with the list marked EX.

93378 Operands are added to support new Option Groups.

93379 Operands are added so that *getconf* can determine supported programming environments.

93380 **Issue 6**

93381 The Open Group Corrigendum U029/4 is applied, correcting the example command in the last
93382 paragraph of the OPTIONS section.

93383 The following new requirements on POSIX implementations derive from alignment with the
93384 Single UNIX Specification:

93385 Operands are added to determine supported programming environments.

93386 This reference page is updated for alignment with the ISO/IEC 9899: 1999 standard. Specifically,
93387 new macros for *c99* programming environments are introduced.

93388 XSI marked *system_var* (XBS5_*) values are marked LEGACY.

93389 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/27 is applied, correcting the descriptions
93390 of *path_var* and *system_var* in the OPERANDS section.

93391 **Issue 7**

93392 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

93393 The EXAMPLES section is corrected.

93394 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0091 [125] is applied.

NAME

getopts ‡'parse utility options

SYNOPSIS

```
getopts optstring name [arg...]
```

DESCRIPTION

The *getopts* utility shall retrieve options and option-arguments from a list of parameters. It shall support the Utility Syntax Guidelines 3 to 10, inclusive, described in XBD Section 12.2 (on page 216).

Each time it is invoked, the *getopts* utility shall place the value of the next option in the shell variable specified by the *name* operand and the index of the next argument to be processed in the shell variable *OPTIND*. Whenever the shell is invoked, *OPTIND* shall be initialized to 1.

When the option requires an option-argument, the *getopts* utility shall place it in the shell variable *OPTARG*. If no option was found, or if the option that was found does not have an option-argument, *OPTARG* shall be unset.

If an option character not contained in the *optstring* operand is found where an option character is expected, the shell variable specified by *name* shall be set to the <question-mark> (`'?'`) character. In this case, if the first character in *optstring* is a <colon> (`':'`), the shell variable *OPTARG* shall be set to the option character found, but no output shall be written to standard error; otherwise, the shell variable *OPTARG* shall be unset and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in *getopts* processing.

If an option-argument is missing:

> If the first character of *optstring* is a <colon>, the shell variable specified by *name* shall be set to the <colon> character and the shell variable *OPTARG* shall be set to the option character found.
>
> Otherwise, the shell variable specified by *name* shall be set to the <question-mark> character, the shell variable *OPTARG* shall be unset, and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in *getopts* processing; a diagnostic message shall be written as stated, but the exit status shall be zero.

When the end of options is encountered, the *getopts* utility shall exit with a return value greater than zero; the shell variable *OPTIND* shall be set to the index of the first operand, or the value `"$#"`+1 if there are no operands; the *name* variable shall be set to the <question-mark> character. Any of the following shall identify the end of options: the first `"--"` argument that is not an option-argument, finding an argument that is not an option-argument and does not begin with a `'-'`, or encountering an error.

The shell variables *OPTIND* and *OPTARG* shall be local to the caller of *getopts* and shall not be exported by default.

The shell variable specified by the *name* operand, *OPTIND*, and *OPTARG* shall affect the current shell execution environment; see Section 2.12 (on page 2381).

If the application sets *OPTIND* to the value 1, a new set of parameters can be used: either the current positional parameters or new *arg* values. Any other attempt to invoke *getopts* multiple times in a single shell execution environment with parameters (positional parameters or *arg* operands) that are not the same in all invocations, or with an *OPTIND* value modified to be a

value other than 1, produces unspecified results.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

optstring A string containing the option characters recognized by the utility invoking *getopts*. If a character is followed by a <colon>, the option shall be expected to have an argument, which should be supplied as a separate argument. Applications should specify an option character and its option-argument as separate arguments, but *getopts* shall interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognized if it is not supplied as a separate argument when *getopts* is invoked. (See also the *getopt*( ) function defined in the System Interfaces volume of POSIX.1-2017.) The characters <question-mark> and <colon> shall not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in *OPTARG* shall be stripped of the option character and the `'-'`. The first character in *optstring* determines how *getopts* behaves if an option character is not known or an option-argument is missing.

name The name of a shell variable that shall be set by the *getopts* utility to the option character that was found.

The *getopts* utility by default shall parse positional parameters passed to the invoking shell procedure. If *arg*s are given, they shall be parsed instead of the positional parameters.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getopts*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

OPTIND This variable shall be used by the *getopts* utility as the index of the next argument to be processed.

93485 **ASYNCHRONOUS EVENTS**
93486 Default.

93487 **STDOUT**
93488 Not used.

93489 **STDERR**
93490 Whenever an error is detected and the first character in the *optstring* operand is not a <colon>
93491 (`':'`), a diagnostic message shall be written to standard error with the following information in
93492 an unspecified format:

93493 The invoking program name shall be identified in the message. The invoking program
93494 name shall be the value of the shell special parameter 0 (see Section 2.5.2, on page 2350) at
93495 the time the *getopts* utility is invoked. A name equivalent to:

93496 `basename "$0"`

93497 may be used.

93498 If an option is found that was not specified in *optstring*, this error is identified and the
93499 invalid option character shall be identified in the message.

93500 If an option requiring an option-argument is found, but an option-argument is not found,
93501 this error shall be identified and the invalid option character shall be identified in the
93502 message.

93503 **OUTPUT FILES**
93504 None.

93505 **EXTENDED DESCRIPTION**
93506 None.

93507 **EXIT STATUS**
93508 The following exit values shall be returned:

93509 0 An option, specified or unspecified by *optstring*, was found.

93510 >0 The end of options was encountered or an error occurred.

93511 **CONSEQUENCES OF ERRORS**
93512 Default.

93513 **APPLICATION USAGE**
93514 Since *getopts* affects the current shell execution environment, it is generally provided as a shell
93515 regular built-in. If it is called in a subshell or separate utility execution environment, such as one
93516 of the following:

```
93517 (getopts abc value "$@")
93518 nohup getopts ...
93519 find . –exec getopts ... \;
```

93520 it does not affect the shell variables in the caller's environment.

93521 Note that shell functions share *OPTIND* with the calling shell even though the positional
93522 parameters are changed. If the calling shell and any of its functions uses *getopts* to parse
93523 arguments, the results are unspecified.

EXAMPLES

The following example script parses and displays its arguments:

```
aflag=
bflag=
while getopts ab: name
do
    case $name in
    a)    aflag=1;;
    b)    bflag=1
          bval="$OPTARG";;
    ?)   printf "Usage: %s: [−a] [−b value] args\n" $0
          exit 2;;
    esac
done
if [ ! −z "$aflag" ]; then
    printf "Option −a specified\n"
fi
if [ ! −z "$bflag" ]; then
    printf 'Option −b "%s" specified\n' "$bval"
fi
shift $(($OPTIND − 1))
printf "Remaining arguments are: %s\n" "$*"
```

RATIONALE

The *getopts* utility was chosen in preference to the System V *getopt* utility because *getopts* handles option-arguments containing <blank> characters.

The *OPTARG* variable is not mentioned in the ENVIRONMENT VARIABLES section because it does not affect the execution of *getopts*; it is one of the few ``output-only'' variables used by the standard utilities.

The <colon> is not allowed as an option character because that is not historical behavior, and it violates the Utility Syntax Guidelines. The <colon> is now specified to behave as in the KornShell version of the *getopts* utility; when used as the first character in the *optstring* operand, it disables diagnostics concerning missing option-arguments and unexpected option characters. This replaces the use of the *OPTERR* variable that was specified in an early proposal.

The formats of the diagnostic messages produced by the *getopts* utility and the *getopt*() function are not fully specified because implementations with superior (``friendlier'') formats objected to the formats used by some historical implementations. The standard developers considered it important that the information in the messages used be uniform between *getopts* and *getopt*(). Exact duplication of the messages might not be possible, particularly if a utility is built on another system that has a different *getopt*() function, but the messages must have specific information included so that the program name, invalid option character, and type of error can be distinguished by a user.

Only a rare application program intercepts a *getopts* standard error message and wants to parse it. Therefore, implementations are free to choose the most usable messages they can devise. The following formats are used by many historical implementations:

```
"%s: illegal option −− %c\n", <program name>, <option character>
```

```
"%s: option requires an argument −− %c\n", <program name>, \
    <option character>
```

Historical shells with built-in versions of *getopt*( ) or *getopts* have used different formats, frequently not even indicating the option character found in error.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0092 [159] is applied.

93585 **NAME**

93586 grep — search a file for a pattern

93587 **SYNOPSIS**

93588 `grep [-E|-F] [-c|-l|-q] [-insvx] -e pattern_list`
93589 `    [-e pattern_list]... [-f pattern_file]... [file...]`

93590 `grep [-E|-F] [-c|-l|-q] [-insvx] [-e pattern_list]...`
93591 `    -f pattern_file [-f pattern_file]... [file...]`

93592 `grep [-E|-F] [-c|-l|-q] [-insvx] pattern_list [file...]`

93593 **DESCRIPTION**

93594 The *grep* utility shall search the input files, selecting lines matching one or more patterns; the
93595 types of patterns are controlled by the options specified. The patterns are specified by the **−e**
93596 option, **−f** option, or the *pattern_list* operand. The *pattern_list*'s value shall consist of one or more
93597 patterns separated by <newline> characters; the *pattern_file*'s contents shall consist of one or
93598 more patterns terminated by a <newline> character. By default, an input line shall be selected if
93599 any pattern, treated as an entire basic regular expression (BRE) as described in XBD Section 9.3
93600 (on page 183), matches any part of the line excluding the terminating <newline>; a null BRE
93601 shall match every line. By default, each selected input line shall be written to the standard
93602 output.

93603 Regular expression matching shall be based on text lines. Since a <newline> separates or
93604 terminates patterns (see the **−e** and **−f** options below), regular expressions cannot contain a
93605 <newline>. Similarly, since patterns are matched against individual lines (excluding the
93606 terminating <newline> characters) of the input, there is no way for a pattern to match a
93607 <newline> found in the input.

93608 **OPTIONS**

93609 The *grep* utility shall conform to XBD Section 12.2 (on page 216).

93610 The following options shall be supported:

93611 **−E** Match using extended regular expressions. Treat each pattern specified as an ERE,
93612 as described in XBD Section 9.4 (on page 188). If any entire ERE pattern matches
93613 some part of an input line excluding the terminating <newline>, the line shall be
93614 matched. A null ERE shall match every line.

93615 **−F** Match using fixed strings. Treat each pattern specified as a string instead of a
93616 regular expression. If an input line contains any of the patterns as a contiguous
93617 sequence of bytes, the line shall be matched. A null string shall match every line.

93618 **−c** Write only a count of selected lines to standard output.

93619 **−e** *pattern_list*
93620 Specify one or more patterns to be used during the search for input. The
93621 application shall ensure that patterns in *pattern_list* are separated by a <newline>.
93622 A null pattern can be specified by two adjacent <newline> characters in
93623 *pattern_list*. Unless the **−E** or **−F** option is also specified, each pattern shall be
93624 treated as a BRE, as described in XBD Section 9.3 (on page 183). Multiple **−e** and **−f**
93625 options shall be accepted by the *grep* utility. All of the specified patterns shall be
93626 used when matching lines, but the order of evaluation is unspecified.

93627 **−f** *pattern_file*
93628 Read one or more patterns from the file named by the pathname *pattern_file*.
93629 Patterns in *pattern_file* shall be terminated by a <newline>. A null pattern can be
93630 specified by an empty line in *pattern_file*. Unless the **−E** or **−F** option is also

specified, each pattern shall be treated as a BRE, as described in XBD Section 9.3 (on page 183).

−i Perform pattern matching in searches without regard to case; see XBD Section 9.2 (on page 182).

−l (The letter ell.) Write only the names of files containing selected lines to standard output. Pathnames shall be written once per file searched. If the standard input is searched, a pathname of `"(standard input)"` shall be written, in the POSIX locale. In other locales, `"standard input"` may be replaced by something more appropriate in those locales.

−n Precede each output line by its relative line number in the file, each file starting at line 1. The line number counter shall be reset for each file processed.

−q Quiet. Nothing shall be written to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.

−s Suppress the error messages ordinarily written for nonexistent or unreadable files. Other error messages shall not be suppressed.

−v Select lines not matching any of the specified patterns. If the **−v** option is not specified, selected lines shall be those that match any of the specified patterns.

−x Consider only input lines that use all characters in the line excluding the terminating <newline> to match an entire fixed string or regular expression to be matching lines.

OPERANDS

The following operands shall be supported:

pattern_list Specify one or more patterns to be used during the search for input. This operand shall be treated as if it were specified as **−e** *pattern_list*.

file A pathname of a file to be searched for the patterns. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'−'` and the implementation treats the `'−'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *grep*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

93673 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
93674 characters (for example, single-byte as opposed to multi-byte characters in
93675 arguments and input files) and the behavior of character classes within regular
93676 expressions.

93677 *LC_MESSAGES*
93678 Determine the locale that should be used to affect the format and contents of
93679 diagnostic messages written to standard error.

93680 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

93681 **ASYNCHRONOUS EVENTS**
93682 Default.

93683 **STDOUT**
93684 If the **−l** option is in effect, the following shall be written for each file containing at least one
93685 selected input line:

93686 `"%s\n", <file>`

93687 Otherwise, if more than one *file* argument appears, and **−q** is not specified, the *grep* utility shall
93688 prefix each output line by:

93689 `"%s:", <file>`

93690 The remainder of each output line shall depend on the other options specified:

93691 If the **−c** option is in effect, the remainder of each output line shall contain:

93692 `"%d\n", <count>`

93693 Otherwise, if **−c** is not in effect and the **−n** option is in effect, the following shall be written
93694 to standard output:

93695 `"%d:", <line number>`

93696 Finally, the following shall be written to standard output:

93697 `"%s", <selected-line contents>`

93698 **STDERR**
93699 The standard error shall be used only for diagnostic messages.

93700 **OUTPUT FILES**
93701 None.

93702 **EXTENDED DESCRIPTION**
93703 None.

93704 **EXIT STATUS**
93705 The following exit values shall be returned:

93706 0 One or more lines were selected.

93707 1 No lines were selected.

93708 >1 An error occurred.

93709 **CONSEQUENCES OF ERRORS**
93710 If the **−q** option is specified, the exit status shall be zero if an input line is selected, even if an
93711 error was detected. Otherwise, default actions shall be performed.

APPLICATION USAGE

Care should be taken when using characters in *pattern_list* that may also be meaningful to the command interpreter. It is safest to enclose the entire *pattern_list* argument in single-quotes:

```
'...'
```

The **−e** *pattern_list* option has the same effect as the *pattern_list* operand, but is useful when *pattern_list* begins with the <hyphen-minus> delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.

Multiple **−e** and **−f** options are accepted and *grep* uses all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)

The **−q** option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it exits zero if it finds a match even if *grep* detected an access or read error on earlier *file* operands).

When using *grep* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

EXAMPLES

1. To find all uses of the word "Posix" (in any case) in file **text.mm** and write with line numbers:

   ```
   grep −i −n posix text.mm
   ```

2. To find all empty lines in the standard input:

   ```
   grep ^$
   ```

   or:

   ```
   grep −v .
   ```

3. Both of the following commands print all lines containing strings "abc" or "def" or both:

   ```
   grep −E 'abc|def'
   ```

   ```
   grep −F 'abc
   def'
   ```

4. Both of the following commands print all lines matching exactly "abc" or "def":

   ```
   grep −E '^abc$|^def$'
   ```

   ```
   grep −F −x 'abc
   def'
   ```

RATIONALE

This *grep* has been enhanced in an upwards-compatible way to provide the exact functionality of the historical *egrep* and *fgrep* commands as well. It was the clear intention of the standard developers to consolidate the three *grep*s into a single command.

The old *egrep* and *fgrep* commands are likely to be supported for many years to come as implementation extensions, allowing historical applications to operate unmodified.

Historical implementations usually silently ignored all but one of multiply-specified **−e** and **−f** options, but were not consistent as to which specification was actually used.

The **−b** option was omitted from the OPTIONS section because block numbers are implementation-defined.

The System V restriction on using − to mean standard input was omitted.

A definition of action taken when given a null BRE or ERE is specified. This is an error condition in some historical implementations.

The **−l** option previously indicated that its use was undefined when no files were explicitly named. This behavior was historical and placed an unnecessary restriction on future implementations. It has been removed.

The historical BSD *grep* **−s** option practice is easily duplicated by redirecting standard output to **/dev/null**. The **−s** option required here is from System V.

The **−x** option, historically available only with *fgrep*, is available here for all of the non-obsolescent versions.

FUTURE DIRECTIONS

None.

NAME

hash — remember or report utility locations

SYNOPSIS

```
hash [utility...]
hash -r
```

DESCRIPTION

The *hash* utility shall affect the way the current shell environment remembers the locations of utilities found as described in Section 2.9.1.1 (on page 2367). Depending on the arguments specified, it shall add utility locations to its list of remembered locations or it shall purge the contents of the list. When no arguments are specified, it shall report on the contents of the list.

Utilities provided as built-ins to the shell shall not be reported by *hash*.

OPTIONS

The *hash* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-r Forget all previously remembered utility locations.

OPERANDS

The following operand shall be supported:

utility The name of a utility to be searched for and added to the list of remembered locations. If *utility* contains one or more <slash> characters, the results are unspecified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *hash*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the location of *utility*, as described in XBD Chapter 8 (on page 173).

93827 **ASYNCHRONOUS EVENTS**
93828 Default.

93829 **STDOUT**
93830 The standard output of *hash* shall be used when no arguments are specified. Its format is
93831 unspecified, but includes the pathname of each utility in the list of remembered locations for the
93832 current shell environment. This list shall consist of those utilities named in previous *hash*
93833 invocations that have been invoked, and may contain those invoked and found through the
93834 normal command search process.

93835 **STDERR**
93836 The standard error shall be used only for diagnostic messages.

93837 **OUTPUT FILES**
93838 None.

93839 **EXTENDED DESCRIPTION**
93840 None.

93841 **EXIT STATUS**
93842 The following exit values shall be returned:

93843 0 Successful completion.

93844 >0 An error occurred.

93845 **CONSEQUENCES OF ERRORS**
93846 Default.

93847 **APPLICATION USAGE**
93848 Since *hash* affects the current shell execution environment, it is always provided as a shell
93849 regular built-in. If it is called in a separate utility execution environment, such as one of the
93850 following:

93851 ```
nohup hash -r
93852 find . -type f | xargs hash
```

93853 it does not affect the command search process of the caller's environment.

93854 The *hash* utility may be implemented as an alias ‡for example*alias* **-t** –, in which case utilities
93855 found through normal command search are not listed by the *hash* command.

93856 The effects of *hash* **-r** can also be achieved portably by resetting the value of *PATH*; in the
93857 simplest form, this can be:

93858 ```
PATH="$PATH"
```

93859 The use of *hash* with *utility* names is unnecessary for most applications, but may provide a
93860 performance improvement on a few implementations; normally, the hashing process is included
93861 by default.

93862 **EXAMPLES**
93863 None.

93864 **RATIONALE**
93865 None.

FUTURE DIRECTIONS

None.

SEE ALSO

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 7

The *hash* utility is moved from the XSI option to the Base.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0093 [241] is applied.

NAME

head ‡'copy the first part of files

SYNOPSIS

```
head [–n number] [file...]
```

DESCRIPTION

The *head* utility shall copy its input files to the standard output, ending the output for each file at a designated point.

Copying shall end at the point in each input file indicated by the **–n** *number* option. The option-argument *number* shall be counted in units of lines.

OPTIONS

The *head* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

–n *number* The first *number* lines of each input file shall be copied to standard output. The application shall ensure that the *number* option-argument is a positive decimal integer.

When a file contains less than *number* lines, it shall be copied to standard output in its entirety. This shall not be an error.

If no options are specified, *head* shall act as if **–n 10** had been specified.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'–'` and the implementation treats the `'–'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

Input files shall be text files, but the line length is not restricted to {LINE_MAX} bytes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *head*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

93917 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

93918 **ASYNCHRONOUS EVENTS**

93919 Default.

93920 **STDOUT**

93921 The standard output shall contain designated portions of the input files.

93922 If multiple *file* operands are specified, *head* shall precede the output for each with the header:

93923 `"\n==> %s <==\n", <pathname>`

93924 except that the first header written shall not include the initial <newline>.

93925 **STDERR**

93926 The standard error shall be used only for diagnostic messages.

93927 **OUTPUT FILES**

93928 None.

93929 **EXTENDED DESCRIPTION**

93930 None.

93931 **EXIT STATUS**

93932 The following exit values shall be returned:

93933 0 Successful completion.

93934 >0 An error occurred.

93935 **CONSEQUENCES OF ERRORS**

93936 Default.

93937 **APPLICATION USAGE**

93938 When using *head* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE
93939 and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte
93940 sequences that do not form valid characters in some locales, in which case the utility's behavior
93941 would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore
93942 this problem is avoided.

93943 **EXAMPLES**

93944 To write the first ten lines of all files (except those with a leading period) in the directory:

93945 `head -- *`

93946 **RATIONALE**

93947 Although it is possible to simulate *head* with *sed* 10q for a single file, the standard developers
93948 decided that the popularity of *head* on historical BSD systems warranted its inclusion alongside
93949 *tail*.

93950 POSIX.1-2017 version of *head* follows the Utility Syntax Guidelines. The **−n** option was added to
93951 this new interface so that *head* and *tail* would be more logically related. Earlier versions of this
93952 standard allowed a **−number** option. This form is no longer specified by POSIX.1-2017 but may
93953 be present in some implementations.

93954 There is no **−c** option (as there is in *tail*) because it is not historical practice and because other
93955 utilities in this volume of POSIX.1-2017 provide similar functionality.

FUTURE DIRECTIONS

None.

SEE ALSO

sed, *tail*

CHANGE HISTORY

First released in Issue 4.

Issue 6

The obsolescent –**number** form is removed.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The DESCRIPTION is updated to clarify that when a file contains less than the number of lines requested, the entire file is copied to standard output.

Issue 7

Austin Group Interpretations 1003.1-2001 #027 and #092 are applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The APPLICATION USAGE section is removed and the EXAMPLES section is corrected.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0107 [663] is applied.

NAME

iconv ‡'codeset conversion

SYNOPSIS

```
iconv [-cs] -f frommap -t tomap [file...]
iconv -f fromcode [-cs] [-t tocode] [file...]
iconv -t tocode [-cs] [-f fromcode] [file...]
iconv -l
```

DESCRIPTION

The *iconv* utility shall convert the encoding of characters in *file* from one codeset to another and write the results to standard output.

When the options indicate that charmap files are used to specify the codesets (see OPTIONS), the codeset conversion shall be accomplished by performing a logical join on the symbolic character names in the two charmaps. The implementation need not support the use of charmap files for codeset conversion unless the POSIX2_LOCALEDEF symbol is defined on the system.

OPTIONS

The *iconv* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-c Omit any characters that are invalid in the codeset of the input file from the output. When **-c** is not used, the results of encountering invalid characters in the input stream (either those that are not characters in the codeset of the input file or that have no corresponding character in the codeset of the output file) shall be specified in the system documentation. The presence or absence of **-c** shall not affect the exit status of *iconv*.

-f *fromcodeset*

Identify the codeset of the input file. The implementation shall recognize the following two forms of the *fromcodeset* option-argument:

fromcode The *fromcode* option-argument must not contain a <slash> character. It shall be interpreted as the name of one of the codeset descriptions provided by the implementation in an unspecified format. Valid values of *fromcode* are implementation-defined.

frommap The *frommap* option-argument must contain a <slash> character. It shall be interpreted as the pathname of a charmap file as defined in XBD Section 6.4 (on page 129). If the pathname does not represent a valid, readable charmap file, the results are undefined.

If this option is omitted, the codeset of the current locale shall be used.

-l Write all supported *fromcode* and *tocode* values to standard output in an unspecified format.

-s Suppress any messages written to standard error concerning invalid characters. When **-s** is not used, the results of encountering invalid characters in the input stream (either those that are not valid characters in the codeset of the input file or that have no corresponding character in the codeset of the output file) shall be specified in the system documentation. The presence or absence of **-s** shall not affect the exit status of *iconv*.

94016 **−t** *tocodeset* Identify the codeset to be used for the output file. The implementation shall
94017 recognize the following two forms of the *tocodeset* option-argument:

94018 *tocode* The semantics shall be equivalent to the **−f** *fromcode* option.

94019 *tomap* The semantics shall be equivalent to the **−f** *frommap* option.

94020 If this option is omitted, the codeset of the current locale shall be used.

94021 If either **−f** or **−t** represents a charmap file, but the other does not (or is omitted), or both **−f** and
94022 **−t** are omitted, the results are undefined.

94023 **OPERANDS**

94024 The following operand shall be supported:

94025 *file* A pathname of an input file. If no *file* operands are specified, or if a *file* operand is
94026 `'−'`, the standard input shall be used.

94027 **STDIN**

94028 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.

94029 **INPUT FILES**

94030 The input file shall be a text file.

94031 **ENVIRONMENT VARIABLES**

94032 The following environment variables shall affect the execution of *iconv*:

94033 *LANG* Provide a default value for the internationalization variables that are unset or null.
94034 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
94035 variables used to determine the values of locale categories.)

94036 *LC_ALL* If set to a non-empty string value, override the values of all the other
94037 internationalization variables.

94038 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
94039 characters (for example, single-byte as opposed to multi-byte characters in
94040 arguments). During translation of the file, this variable is superseded by the use of
94041 the *fromcode* option-argument.

94042 *LC_MESSAGES*
94043 Determine the locale that should be used to affect the format and contents of
94044 diagnostic messages written to standard error.

94045 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

94046 **ASYNCHRONOUS EVENTS**

94047 Default.

94048 **STDOUT**

94049 When the **−l** option is used, the standard output shall contain all supported *fromcode* and *tocode*
94050 values, written in an unspecified format.

94051 When the **−l** option is not used, the standard output shall contain the sequence of characters
94052 read from the input files, translated to the specified codeset. Nothing else shall be written to the
94053 standard output.

94054 **STDERR**

94055 The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The user must ensure that both charmap files use the same symbolic names for characters the two codesets have in common.

EXAMPLES

The following example converts the contents of file **mail.x400** from the ISO/IEC 6937:2001 standard codeset to the ISO/IEC 8859-1:1998 standard codeset, and stores the results in file **mail.local**:

```
iconv –f IS6937 –t IS8859 mail.x400 > mail.local
```

RATIONALE

The *iconv* utility can be used portably only when the user provides two charmap files as option-arguments. This is because a single charmap provided by the user cannot reliably be joined with the names in a system-provided character set description. The valid values for *fromcode* and *tocode* are implementation-defined and do not have to have any relation to the charmap mechanisms. As an aid to interactive users, the **–l** option was adopted from the Plan 9 operating system. It writes information concerning these implementation-defined values. The format is unspecified because there are many possible useful formats that could be chosen, such as a matrix of valid combinations of *fromcode* and *tocode*. The **–l** option is not intended for shell script usage; conforming applications will have to use charmaps.

The *iconv* utility may support the conversion between ASCII and EBCDIC-based encodings, but is not required to do so. In an XSI-compliant implementation, the *dd* utility is the only method guaranteed to support conversion between these two character sets.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Issue 6

This utility has been rewritten to align with the IEEE P1003.2b draft standard. Specifically, the ability to use charmap files for conversion has been added.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/29 is applied, making changes to address inconsistencies with the *iconv*( ) function in the System Interfaces volume of POSIX.1-2017.

Issue 7

Austin Group Interpretation 1003.1-2001 #206 is applied, correcting the *tomap* option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0094 [291] and XCU/TC1-2008/0095 [291] are applied.

NAME

id — return user identity

SYNOPSIS

```
id [user]
id -G [-n] [user]
id -g [-nr] [user]
id -u [-nr] [user]
```

DESCRIPTION

If no *user* operand is provided, the *id* utility shall write the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both shall be written. If multiple groups are supported by the underlying system (see the description of {NGROUPS_MAX} in the System Interfaces volume of POSIX.1-2017), the supplementary group affiliations of the invoking process shall also be written.

If a *user* operand is provided and the process has appropriate privileges, the user and group IDs of the selected user shall be written. In this case, effective IDs shall be assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, these shall be written in the same manner as the supplementary groups described in the preceding paragraph.

OPTIONS

The *id* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-G Output all different group IDs (effective, real, and supplementary) only, using the format `"%u\n"`. If there is more than one distinct group affiliation, output each such affiliation, using the format `" %u"`, before the <newline> is output.

-g Output only the effective group ID, using the format `"%u\n"`.

-n Output the name in the format `"%s"` instead of the numeric ID using the format `"%u"`.

-r Output the real ID instead of the effective ID.

-u Output only the effective user ID, using the format `"%u\n"`.

OPERANDS

The following operand shall be supported:

user The login name for which information is to be written.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *id*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

94146 *LC_ALL* If set to a non-empty string value, override the values of all the other
94147 internationalization variables.

94148 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
94149 characters (for example, single-byte as opposed to multi-byte characters in
94150 arguments).

94151 *LC_MESSAGES*
94152 Determine the locale that should be used to affect the format and contents of
94153 diagnostic messages written to standard error and informative messages written to
94154 standard output.

94155 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

94156 **ASYNCHRONOUS EVENTS**
94157 Default.

94158 **STDOUT**
94159 The following formats shall be used when the *LC_MESSAGES* locale category specifies the
94160 POSIX locale. In other locales, the strings *uid*, *gid*, *euid*, *egid*, and *groups* may be replaced with
94161 more appropriate strings corresponding to the locale.

94162 `"uid=%u(%s) gid=%u(%s)\n", <real user ID>, <user-name>,`
94163 `    <real group ID>, <group-name>`

94164 If the effective and real user IDs do not match, the following shall be inserted immediately
94165 before the `'\n'` character in the previous format:

94166 `" euid=%u(%s)"`

94167 with the following arguments added at the end of the argument list:

94168 `<effective user ID>, <effective user-name>`

94169 If the effective and real group IDs do not match, the following shall be inserted directly before
94170 the `'\n'` character in the format string (and after any addition resulting from the effective and
94171 real user IDs not matching):

94172 `" egid=%u(%s)"`

94173 with the following arguments added at the end of the argument list:

94174 `<effective group-ID>, <effective group name>`

94175 If the process has supplementary group affiliations or the selected user is allowed to belong to
94176 multiple groups, the first shall be added directly before the <newline> in the format string:

94177 `" groups=%u(%s)"`

94178 with the following arguments added at the end of the argument list:

94179 `<supplementary group ID>, <supplementary group name>`

94180 and the necessary number of the following added after that for any remaining supplementary
94181 group IDs:

94182 `",%u(%s)"`

94183 and the necessary number of the following arguments added at the end of the argument list:

94184 `<supplementary group ID>, <supplementary group name>`

94185 If any of the user ID, group ID, effective user ID, effective group ID, or supplementary/multiple

group IDs cannot be mapped by the system into printable user or group names, the corresponding `"(%s)"` and *name* argument shall be omitted from the corresponding format string.

When any of the options are specified, the output format shall be as described in the OPTIONS section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Output produced by the **−G** option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups. (On systems with user and group IDs that are 32-bit integers and with group names with a maximum of 8 bytes per name, 93 supplementary groups plus distinct effective and real group and user IDs could theoretically overflow the 2 048-byte {LINE_MAX} text file line limit on the default output case. It would take about 186 supplementary groups to overflow the 2 048-byte barrier using *id* **−G**). This is not expected to be a problem in practice, but in cases where it is a concern, applications should consider using *fold* **−s** before post-processing the output of *id*.

EXAMPLES

None.

RATIONALE

The functionality provided by the 4 BSD *groups* utility can be simulated using:

```
id −Gn [ user ]
```

The 4 BSD command *groups* was considered, but it was not included because it did not provide the functionality of the *id* utility of the SVID. Also, it was thought that it would be easier to modify *id* to provide the additional functionality necessary to systems with multiple groups than to invent another command.

The options **−u**, **−g**, **−n**, and **−r** were added to ease the use of *id* with shell commands substitution. Without these options it is necessary to use some preprocessor such as *sed* to select the desired piece of information. Since output such as that produced by:

```
id −u −n
```

is frequently wanted, it seemed desirable to add the options.

94226 **FUTURE DIRECTIONS**

94227 None.

NAME

ipcrm — remove an XSI message queue, semaphore set, or shared memory segment identifier

SYNOPSIS

XSI
```
ipcrm [-q msgid|-Q msgkey|-s semid|-S semkey|-m shmid|-M shmkey]...
```

DESCRIPTION

The *ipcrm* utility shall remove zero or more message queues, semaphore sets, or shared memory segments. The interprocess communication facilities to be removed are specified by the options.

Only a user with appropriate privileges shall be allowed to remove an interprocess communication facility that was not created by or owned by the user invoking *ipcrm*.

OPTIONS

The *ipcrm* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-q *msgid* Remove the message queue identifier *msgid* from the system and destroy the message queue and data structure associated with it.

-m *shmid* Remove the shared memory identifier *shmid* from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

-s *semid* Remove the semaphore identifier *semid* from the system and destroy the set of semaphores and data structure associated with it.

-Q *msgkey* Remove the message queue identifier, created with key *msgkey*, from the system and destroy the message queue and data structure associated with it.

-M *shmkey* Remove the shared memory identifier, created with key *shmkey*, from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

-S *semkey* Remove the semaphore identifier, created with key *semkey*, from the system and destroy the set of semaphores and data structure associated with it.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ipcrm*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

CHANGE HISTORY

First released in Issue 5.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ipcs — report XSI interprocess communication facilities status

SYNOPSIS

XSI

```
ipcs [−qms] [−a|−bcopt]
```

DESCRIPTION

The *ipcs* utility shall write information about active interprocess communication facilities.

Without options, information shall be written in short format for message queues, shared memory segments, and semaphore sets that are currently active in the system. Otherwise, the information that is displayed is controlled by the options specified.

OPTIONS

The *ipcs* utility shall conform to XBD Section 12.2 (on page 216).

The *ipcs* utility accepts the following options:

−q Write information about active message queues.

−m Write information about active shared memory segments.

−s Write information about active semaphore sets.

If **−q**, **−m**, or **−s** are specified, only information about those facilities shall be written. If none of these three are specified, information about all three shall be written subject to the following options:

−a Use all print options. (This is a shorthand notation for **−b**, **−c**, **−o**, **−p**, and **−t**.)

−b Write information on maximum allowable size. (Maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores.)

−c Write creator's user name and group name; see below.

−o Write information on outstanding usage. (Number of messages on queue and total number of bytes in messages on queue for message queues, and number of processes attached to shared memory segments.)

−p Write process number information. (Process ID of the last process to send a message and process ID of the last process to receive a message on message queues, process ID of the creating process, and process ID of the last process to attach or detach on shared memory segments.)

−t Write time information. (Time of the last control operation that changed the access permissions for all facilities, time of the last *msgsnd*( ) and *msgrcv*( ) operations on message queues, time of the last *shmat*( ) and *shmdt*( ) operations on shared memory, and time of the last *semop*( ) operation on semaphores.)

OPERANDS

None.

STDIN

Not used.

INPUT FILES

The group database

94354 The user database

94355 **ENVIRONMENT VARIABLES**

94356 The following environment variables shall affect the execution of *ipcs*:

94357 *LANG* Provide a default value for the internationalization variables that are unset or null.
94358 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
94359 variables used to determine the values of locale categories.)

94360 *LC_ALL* If set to a non-empty string value, override the values of all the other
94361 internationalization variables.

94362 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
94363 characters (for example, single-byte as opposed to multi-byte characters in
94364 arguments).

94365 *LC_MESSAGES*
94366 Determine the locale that should be used to affect the format and contents of
94367 diagnostic messages written to standard error.

94368 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

94369 *TZ* Determine the timezone for the date and time strings written by *ipcs*. If *TZ* is unset
94370 or null, an unspecified default timezone shall be used.

94371 **ASYNCHRONOUS EVENTS**

94372 Default.

94373 **STDOUT**

94374 An introductory line shall be written with the format:

94375 `"IPC status from %s as of %s\n", <`*source*`>, <`*date*`>`

94376 where <*source*> indicates the source used to gather the statistics and <*date*> is the information
94377 that would be produced by the *date* command when invoked in the POSIX locale.

94378 The *ipcs* utility then shall create up to three reports depending upon the **−q**, **−m**, and **−s** options.
94379 The first report shall indicate the status of message queues, the second report shall indicate the
94380 status of shared memory segments, and the third report shall indicate the status of semaphore
94381 sets.

94382 If the corresponding facility is not installed or has not been used since the last reboot, then the
94383 report shall be written out in the format:

94384 `"%s facility not in system.\n", <`*facility*`>`

94385 where <*facility*> is *Message Queue*, *Shared Memory*, or *Semaphore*, as appropriate. If the facility has
94386 been installed and has been used since the last reboot, column headings separated by one or
94387 more <space> characters and followed by a <newline> shall be written as indicated below
94388 followed by the facility name written out using the format:

94389 `"%s:\n", <`*facility*`>`

94390 where <*facility*> is *Message Queues*, *Shared Memory*, or *Semaphores*, as appropriate. On the second
94391 and third reports the column headings need not be written if the last column headings written
94392 already provide column headings for all information in that report.

94393 The column headings provided in the first column below and the meaning of the information in
94394 those columns shall be given in order below; the letters in parentheses indicate the options that
94395 shall cause the corresponding column to appear; ``all'' means that the column shall always
94396 appear. Each column is separated by one or more <space> characters. Note that these options

only determine what information is provided for each report; they do not determine which reports are written.

T (all) Type of facility:

`q` Message queue.

`m` Shared memory segment.

`s` Semaphore.

This field is a single character written using the format `%c`.

ID (all) The identifier for the facility entry. This field shall be written using the format `%d`.

KEY (all) The key used as an argument to *msgget*(), *semget*(), or *shmget*() to create the facility entry.

Note: The key of a shared memory segment is changed to IPC_PRIVATE when the segment has been removed until all processes attached to the segment detach it.

This field shall be written using the format `0x%x`.

MODE (all) The facility access modes and flags. The mode shall consist of 11 characters that are interpreted as follows.

The first character shall be:

`S` If a process is waiting on a *msgsnd*() operation.

– If the above is not true.

The second character shall be:

`R` If a process is waiting on a *msgrcv*() operation.

`C` or – If the associated shared memory segment is to be cleared when the first attach operation is executed.

– If none of the above is true.

The next nine characters shall be interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the usergroup of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is a <hyphen-minus> (`'-'`).

The permissions shall be indicated as follows:

r If read permission is granted.

w If write permission is granted.

a If alter permission is granted.

– If the indicated permission is not granted.

The first character following the permissions specifies if there is an alternate or additional access control method associated with the facility. If there is no alternate or additional access control method associated with the facility, a single <space> shall be written; otherwise, another printable character is

written.

OWNER (all) The user name of the owner of the facility entry. If the user name of the owner is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the owner shall be written using the format `%d`.

GROUP (all) The group name of the owner of the facility entry. If the group name of the owner is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the owner shall be written using the format `%d`.

The following nine columns shall be only written out for message queues:

CREATOR (**a**,**c**) The user name of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

CBYTES (**a**,**o**) The number of bytes in messages currently outstanding on the associated message queue. This field shall be written using the format `%d`.

QNUM (**a**,**o**) The number of messages currently outstanding on the associated message queue. This field shall be written using the format `%d`.

QBYTES (**a**,**b**) The maximum number of bytes allowed in messages outstanding on the associated message queue. This field shall be written using the format `%d`.

LSPID (**a**,**p**) The process ID of the last process to send a message to the associated queue. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no message has been sent to the corresponding message queue; otherwise, <*pid*> shall be the process ID of the last process to send a message to the queue.

LRPID (**a**,**p**) The process ID of the last process to receive a message from the associated queue. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no message has been received from the corresponding message queue; otherwise, <*pid*> shall be the process ID of the last process to receive a message from the queue.

STIME (**a**,**t**) The time the last message was sent to the associated queue. If a message has been sent to the corresponding message queue, the hour, minute, and second of the last time a message was sent to the queue shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

RTIME (**a**,**t**) The time the last message was received from the associated queue. If a message has been received from the corresponding message queue, the hour, minute, and second of the last time a message was received from the queue

94481 shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format
94482 `" no-entry"` shall be written.

94483 The following eight columns shall be only written out for shared memory segments.

94484 CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is
94485 found in the user database, at least the first eight column positions of the
94486 name shall be written using the format `%s`. Otherwise, the user ID of the
94487 creator shall be written using the format `%d`.

94488 CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the
94489 creator is found in the group database, at least the first eight column positions
94490 of the name shall be written using the format `%s`. Otherwise, the group ID of
94491 the creator shall be written using the format `%d`.

94492 NATTCH (**a**,**o**) The number of processes attached to the associated shared memory segment.
94493 This field shall be written using the format `%d`.

94494 SEGSZ (**a**,**b**) The size of the associated shared memory segment. This field shall be written
94495 using the format `%d`.

94496 CPID (**a**,**p**) The process ID of the creator of the shared memory entry. This field shall be
94497 written using the format `%d`.

94498 LPID (**a**,**p**) The process ID of the last process to attach or detach the shared memory
94499 segment. This field shall be written using the format:

94500 `"%d", <`*pid*`>`

94501 where <*pid*> is 0 if no process has attached the corresponding shared memory
94502 segment; otherwise, <*pid*> shall be the process ID of the last process to attach
94503 or detach the segment.

94504 ATIME (**a**,**t**) The time the last attach on the associated shared memory segment was
94505 completed. If the corresponding shared memory segment has ever been
94506 attached, the hour, minute, and second of the last time the segment was
94507 attached shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the
94508 format `" no-entry"` shall be written.

94509 DTIME (**a**,**t**) The time the last detach on the associated shared memory segment was
94510 completed. If the corresponding shared memory segment has ever been
94511 detached, the hour, minute, and second of the last time the segment was
94512 detached shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the
94513 format `" no-entry"` shall be written.

94514 The following four columns shall be only written out for semaphore sets:

94515 CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is
94516 found in the user database, at least the first eight column positions of the
94517 name shall be written using the format `%s`. Otherwise, the user ID of the
94518 creator shall be written using the format `%d`.

94519 CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the
94520 creator is found in the group database, at least the first eight column positions
94521 of the name shall be written using the format `%s`. Otherwise, the group ID of
94522 the creator shall be written using the format `%d`.

NSEMS (**a**,**b**) The number of semaphores in the set associated with the semaphore entry. This field shall be written using the format `%d`.

OTIME (**a**,**t**) The time the last semaphore operation on the set associated with the semaphore entry was completed. If a semaphore operation has ever been performed on the corresponding semaphore set, the hour, minute, and second of the last semaphore operation on the semaphore set shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following column shall be written for all three reports when it is requested:

CTIME (**a**,**t**) The time the associated entry was created or changed. The hour, minute, and second of the time when the associated entry was created shall be written using the format `%d:%2.2d:%2.2d`.

STDERR

The standard error shall be used only for diagnostic messages.

NAME

jobs — display status of jobs in the current session

SYNOPSIS

UP

```
jobs [−l|−p] [job_id...]
```

DESCRIPTION

The *jobs* utility shall display the status of jobs that were started in the current shell environment; see Section 2.12 (on page 2381).

When *jobs* reports the termination status of a job, the shell shall remove its process ID from the list of those ``known in the current shell execution environment''; see Section 2.9.3.1 (on page 2370).

OPTIONS

The *jobs* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−l (The letter ell.) Provide more information about each job listed. This information shall include the job number, current job, process group ID, state, and the command that formed the job.

−p Display only the process IDs for the process group leaders of the selected jobs.

By default, the *jobs* utility shall display the status of all stopped jobs, running background jobs and all jobs whose status has changed and have not been reported by the shell.

OPERANDS

The following operand shall be supported:

job_id Specifies the jobs for which the status is to be displayed. If no *job_id* is given, the status information for all jobs shall be displayed. The format of *job_id* is described in XBD Section 3.204 (on page 66).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *jobs*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

94612 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

94613 **ASYNCHRONOUS EVENTS**

94614 Default.

94615 **STDOUT**

94616 If the **–p** option is specified, the output shall consist of one line for each process ID:

94617 `"%d\n", <process ID>`

94618 Otherwise, if the **–l** option is not specified, the output shall be a series of lines of the form:

94619 `"[%d] %c %s %s\n", <job-number>, <current>, <state>, <command>`

94620 where the fields shall be as follows:

94621 <*current*> The character `'+'` identifies the job that would be used as a default for the *fg* or *bg*
94622 utilities; this job can also be specified using the *job_id* %+ or `"%%"`. The character
94623 `'−'` identifies the job that would become the default if the current default job were
94624 to exit; this job can also be specified using the *job_id* %–. For other jobs, this field is
94625 a <space>. At most one job can be identified with `'+'` and at most one job can be
94626 identified with `'−'`. If there is any suspended job, then the current job shall be a
94627 suspended job. If there are at least two suspended jobs, then the previous job also
94628 shall be a suspended job.

94629 <*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*, and *kill*
94630 utilities. Using these utilities, the job can be identified by prefixing the job number
94631 with `'%'`.

94632 <*state*> One of the following strings (in the POSIX locale):

94633 **Running** Indicates that the job has not been suspended by a signal and has not
94634 exited.

94635 **Done** Indicates that the job completed and returned exit status zero.

94636 **Done**(*code*) Indicates that the job completed normally and that it exited with the
94637 specified non-zero exit status, *code*, expressed as a decimal number.

94638 **Stopped** Indicates that the job was suspended by the SIGTSTP signal.

94639 **Stopped** (**SIGTSTP**)
94640 Indicates that the job was suspended by the SIGTSTP signal.

94641 **Stopped** (**SIGSTOP**)
94642 Indicates that the job was suspended by the SIGSTOP signal.

94643 **Stopped** (**SIGTTIN**)
94644 Indicates that the job was suspended by the SIGTTIN signal.

94645 **Stopped** (**SIGTTOU**)
94646 Indicates that the job was suspended by the SIGTTOU signal.

94647 The implementation may substitute the string **Suspended** in place of **Stopped**. If
94648 the job was terminated by a signal, the format of <*state*> is unspecified, but it shall
94649 be visibly distinct from all of the other <*state*> formats shown here and shall
94650 indicate the name or description of the signal causing the termination.

94651 <*command*> The associated command that was given to the shell.

94652 If the **–l** option is specified, a field containing the process group ID shall be inserted before the
94653 <*state*> field. Also, more processes in a process group may be output on separate lines, using

only the process ID and <*command*> fields.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **−p** option is the only portable way to find out the process group of a job because different implementations have different strategies for defining the process group of the job. Usage such as $(*jobs* **−p**) provides a way of referring to the process group of the job in an implementation-independent way.

The *jobs* utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for *bg*. For this reason, *jobs* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

Both `"%%"` and `"%+"` are used to refer to the current job. Both forms are of equal validity ‡the `"%%"` mirroring `"$$"` and `"%+"` mirroring the output of *jobs*. Both forms reflect historical practice of the KornShell and the C shell with job control.

The job control features provided by *bg*, *fg*, and *jobs* are based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of POSIX.1-2017 to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

The *jobs* utility is not dependent on the job control option, as are the seemingly related *bg* and *fg* utilities because *jobs* is useful for examining background jobs, regardless of the condition of job control. When the user has invoked a *set* **+m** command and job control has been turned off, *jobs* can still be used to examine the background jobs associated with that current session. Similarly, *kill* can then be used to kill background jobs with *kill* %<*background job number*>.

The output for terminated jobs is left unspecified to accommodate various historical systems. The following formats have been witnessed:

1. **Killed**(*signal name*)
2. *signal name*

3. *signal name*(**coredump**)
4. *signal description*– **core dumped**

Most users should be able to understand these formats, although it means that applications have trouble parsing them.

The calculation of job IDs was not described since this would suggest an implementation, which may impose unnecessary restrictions.

In an early proposal, a –**n** option was included to ``Display the status of jobs that have changed, exited, or stopped since the last status report''. It was removed because the shell always writes any changed status of jobs before each prompt.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The JC shading is removed as job control is mandatory in this version.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

join — relational database operator

SYNOPSIS

```
join [−a file_number|−v file_number] [−e string] [−o list] [−t char]
    [−1 field] [−2 field] file1 file2
```

DESCRIPTION

The *join* utility shall perform an equality join on the files *file1* and *file2*. The joined files shall be written to the standard output.

The join field is a field in each file on which the files are compared. The *join* utility shall write one line in the output for each pair of lines in *file1* and *file2* that have join fields that collate equally. The output line by default shall consist of the join field, then the remaining fields from *file1*, then the remaining fields from *file2*. This format can be changed by using the **−o** option (see below). The **−a** option can be used to add unmatched lines to the output. The **−v** option can be used to output only unmatched lines.

The files *file1* and *file2* shall be ordered in the collating sequence of *sort* **−b** on the fields on which they shall be joined, by default the first in each line. All selected output shall be written in the same collating sequence.

The default input field separators shall be <blank> characters. In this case, multiple separators shall count as one field separator, and leading separators shall be ignored. The default output field separator shall be a <space>.

The field separator and collating sequence can be changed by using the **−t** option (see below).

If the same key appears more than once in either file, all combinations of the set of remaining fields in *file1* and the set of remaining fields in *file2* are output in the order of the lines encountered.

If the input files are not in the appropriate collating sequence, the results are unspecified.

OPTIONS

The *join* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−a *file_number*
: Produce a line for each unpairable line in file *file_number*, where *file_number* is 1 or 2, in addition to the default output. If both **−a**1 and **−a**2 are specified, all unpairable lines shall be output.

−e *string*
: Replace empty output fields in the list selected by **−o** with the string *string*.

−o *list*
: Construct the output line to comprise the fields specified in *list*, each element of which shall have one of the following two forms:

  1. *file_number.field*, where *file_number* is a file number and *field* is a decimal integer field number
  2. 0 (zero), representing the join field

  The elements of *list* shall be either <comma>-separated or <blank>-separated, as specified in Guideline 8 of XBD Section 12.2 (on page 216). The fields specified by *list* shall be written for all selected output lines. Fields selected by *list* that do not appear in the input shall be treated as empty output fields. (See the **−e** option.) Only specifically requested fields shall be written. The application shall ensure that *list* is a single command line argument.

94761 **−t** *char* Use character *char* as a separator, for both input and output. Every appearance of
94762 *char* in a line shall be significant. When this option is specified, the collating
94763 sequence shall be the same as *sort* without the **−b** option.

94764 **−v** *file_number*
94765 Instead of the default output, produce a line only for each unpairable line in
94766 *file_number*, where *file_number* is 1 or 2. If both **−v**1 and **−v**2 are specified, all
94767 unpairable lines shall be output.

94768 **−1** *field* Join on the *field*th field of file 1. Fields are decimal integers starting with 1.

94769 **−2** *field* Join on the *field*th field of file 2. Fields are decimal integers starting with 1.

94770 **OPERANDS**
94771 The following operands shall be supported:

94772 *file1*, *file2* A pathname of a file to be joined. If either of the *file1* or *file2* operands is `'−'`, the
94773 standard input shall be used in its place.

94774 **STDIN**
94775 The standard input shall be used only if the *file1* or *file2* operand is `'−'`. See the INPUT FILES
94776 section.

94777 **INPUT FILES**
94778 The input files shall be text files.

94779 **ENVIRONMENT VARIABLES**
94780 The following environment variables shall affect the execution of *join*:

94781 *LANG* Provide a default value for the internationalization variables that are unset or null.
94782 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
94783 variables used to determine the values of locale categories.)

94784 *LC_ALL* If set to a non-empty string value, override the values of all the other
94785 internationalization variables.

94786 *LC_COLLATE*
94787 Determine the locale of the collating sequence *join* expects to have been used when
94788 the input files were sorted.

94789 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
94790 characters (for example, single-byte as opposed to multi-byte characters in
94791 arguments and input files).

94792 *LC_MESSAGES*
94793 Determine the locale that should be used to affect the format and contents of
94794 diagnostic messages written to standard error.

94795 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

94796 **ASYNCHRONOUS EVENTS**
94797 Default.

94798 **STDOUT**
94799 The *join* utility output shall be a concatenation of selected character fields. When the **−o** option
94800 is not specified, the output shall be:

94801 `"%s%s%s\n", <join field>, <other file1 fields>,`
94802 `    <other file2 fields>`

94803 If the join field is not the first field in a file, the <*other file fields*> for that file shall be:

94804 `<fields preceding join field>, <fields following join field>`

94805 When the **–o** option is specified, the output format shall be:

94806 `"%s\n", <concatenation of fields>`

94807 where the concatenation of fields is described by the **–o** option, above.

94808 For either format, each field (except the last) shall be written with its trailing separator character.
94809 If the separator is the default (<blank> characters), a single <space> shall be written after each
94810 field (except the last).

94811 **STDERR**

94812 The standard error shall be used only for diagnostic messages.

94813 **OUTPUT FILES**

94814 None.

94815 **EXTENDED DESCRIPTION**

94816 None.

94817 **EXIT STATUS**

94818 The following exit values shall be returned:

94819 0 All input files were output successfully.

94820 >0 An error occurred.

94821 **CONSEQUENCES OF ERRORS**

94822 Default.

94823 **APPLICATION USAGE**

94824 Pathnames consisting of numeric digits or of the form *string.string* should not be specified
94825 directly following the **–o** list.

94826 If the collating sequence of the current locale does not have a total ordering of all characters (see
94827 XBD Section 7.3.2, on page 147), *join* treats fields that collate equally but are not identical as
94828 being the same. If this behavior is not desired, it can be avoided by forcing the use of the POSIX
94829 locale (although this means re-sorting the input files into the POSIX locale collating sequence.)

94830 When using *join* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE
94831 and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte
94832 sequences that do not form valid characters in some locales, in which case the utility's behavior
94833 would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore
94834 this problem is avoided.

94835 **EXAMPLES**

94836 The **–o** 0 field essentially selects the union of the join fields. For example, given file **phone**:

```
94837 !Name           Phone Number
94838 Don             +1 123-456-7890
94839 Hal             +1 234-567-8901
94840 Yasushi         +2 345-678-9012
```

94841 and file **fax**:

```
94842 !Name           Fax Number
94843 Don             +1 123-456-7899
94844 Keith           +1 456-789-0122
94845 Yasushi         +2 345-678-9011
```

(where the large expanses of white space are meant to each represent a single <tab>), the command:

```
join -t "<tab>" -a 1 -a 2 -e '(unknown)' -o 0,1.2,2.2 phone fax
```

(where `<tab>` is a literal <tab> character) would produce:

```
!Name           Phone Number            Fax Number
Don             +1 123-456-7890         +1 123-456-7899
Hal             +1 234-567-8901         (unknown)
Keith           (unknown)               +1 456-789-0122
Yasushi         +2 345-678-9012         +2 345-678-9011
```

Multiple instances of the same key will produce combinatorial results. The following:

```
fa:
    a x
    a y
    a z
fb:
    a p
```

will produce:

```
a x p
a y p
a z p
```

And the following:

```
fa:
    a b c
    a d e
fb:
    a w x
    a y z
    a o p
```

will produce:

```
a b c w x
a b c y z
a b c o p
a d e w x
a d e y z
a d e o p
```

RATIONALE

The **-e** option is only effective when used with **-o** because, unless specific fields are identified using **-o**, *join* is not aware of what fields might be empty. The exception to this is the join field, but identifying an empty join field with the **-e** string is not historical practice and some scripts might break if this were changed.

The 0 field in the **-o** list was adopted from the Tenth Edition version of *join* to satisfy international objections that the *join* in the base documents for IEEE Std 1003.2-1992 did not support the ``full join'' or ``outer join'' described in relational database literature. Although it has been possible to include a join field in the output (by default, or by field number using **-o**), the join field could not be included for an unpaired line selected by **-a**. The **-o** 0 field essentially

selects the union of the join fields.

This sort of outer join was not possible with the *join* commands in the base documents for IEEE Std 1003.2-1992. The **−o** 0 field was chosen because it is an upwards-compatible change for applications. An alternative was considered: have the join field represent the union of the fields in the files (where they are identical for matched lines, and one or both are null for unmatched lines). This was not adopted because it would break some historical applications.

The ability to specify *file2* as − is not historical practice; it was added for completeness.

The **−v** option is not historical practice, but was considered necessary because it permitted the writing of *only* those lines that do not match on the join field, as opposed to the **−a** option, which prints both lines that do and do not match. This additional facility is parallel with the **−v** option of *grep*.

Some historical implementations have been encountered where a blank line in one of the input files was considered to be the end of the file; the description in this volume of POSIX.1-2017 does not cite this as an allowable case.

Earlier versions of this standard allowed **−j**, **−j1**, **−j2** options, and a form of the **−o** option that allowed the *list* option-argument to be multiple arguments. These forms are no longer specified by POSIX.1-2017 but may be present in some implementations.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent **−j** options and the multi-argument **−o** option are removed in this version.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0109 [963], XCU/TC2-2008/0110 [663], XCU/TC2-2008/0111 [971], and XCU/TC2-2008/0112 [885] are applied.

NAME

kill — terminate or signal processes

SYNOPSIS

```
kill −s signal_name pid...
kill −l [exit_status]
```

XSI

```
kill [−signal_name] pid...
kill [−signal_number] pid...
```

DESCRIPTION

The *kill* utility shall send a signal to the process or processes specified by each *pid* operand.

For each *pid* operand, the *kill* utility shall perform actions equivalent to the *kill*( ) function defined in the System Interfaces volume of POSIX.1-2017 called with the following arguments:

The value of the *pid* operand shall be used as the *pid* argument.

The *sig* argument is the value specified by the **−s** option, *−signal_number* option, or the *−signal_name* option, or by SIGTERM, if none of these options is specified.

OPTIONS

XSI The *kill* utility shall conform to XBD Section 12.2 (on page 216), except that in the last two SYNOPSIS forms, the *−signal_number* and *−signal_name* options are usually more than a single character.

The following options shall be supported:

−l (The letter ell.) Write all values of *signal_name* supported by the implementation, if no operand is given. If an *exit_status* operand is given and it is a value of the `'?'` shell special parameter (see Section 2.5.2 (on page 2350) and *wait*) corresponding to a process that was terminated by a signal, the *signal_name* corresponding to the signal that terminated the process shall be written. If an *exit_status* operand is given and it is the unsigned decimal integer value of a signal number, the *signal_name* (the symbolic constant name without the **SIG** prefix defined in the Base Definitions volume of POSIX.1-2017) corresponding to that signal shall be written. Otherwise, the results are unspecified.

−s *signal_name*
Specify the signal to send, using one of the symbolic names defined in the **<signal.h>** header. Values of *signal_name* shall be recognized in a case-independent fashion, without the **SIG** prefix. In addition, the symbolic name 0 shall be recognized, representing the signal value zero. The corresponding signal shall be sent instead of SIGTERM.

XSI *−signal_name*
Equivalent to **−s** *signal_name*.

XSI *−signal_number*
Specify a non-negative decimal integer, *signal_number*, representing the signal to be used instead of SIGTERM, as the *sig* argument in the effective call to *kill*( ). The correspondence between integer values and the *sig* value used is shown in the following list.

The effects of specifying any *signal_number* other than those listed below are undefined.

94966 0 0
94967 1 SIGHUP
94968 2 SIGINT
94969 3 SIGQUIT
94970 6 SIGABRT
94971 9 SIGKILL
94972 14 SIGALRM
94973 15 SIGTERM

94974 If the first argument is a negative integer, it shall be interpreted as a *–signal_number*
94975 option, not as a negative *pid* operand specifying a process group.

94976 **OPERANDS**

94977 The following operands shall be supported:

94978 *pid* One of the following:

94979 1. A decimal integer specifying a process or process group to be signaled. The
94980 process or processes selected by positive, negative, and zero values of the
94981 *pid* operand shall be as described for the *kill*( ) function. If process number 0
94982 is specified, all processes in the current process group shall be signaled. For
94983 the effects of negative *pid* numbers, see the *kill*( ) function defined in the
94984 System Interfaces volume of POSIX.1-2017. If the first *pid* operand is
94985 negative, it should be preceded by `"--"` to keep it from being interpreted as
94986 an option.

94987 2. A job control job ID (see XBD Section 3.204, on page 66) that identifies a
94988 background process group to be signaled. The job control job ID notation is
94989 applicable only for invocations of *kill* in the current shell execution
94990 environment; see Section 2.12 (on page 2381).

94991 *exit_status* A decimal integer specifying a signal number or the exit status of a process
94992 terminated by a signal.

94993 **STDIN**

94994 Not used.

94995 **INPUT FILES**

94996 None.

94997 **ENVIRONMENT VARIABLES**

94998 The following environment variables shall affect the execution of *kill*:

94999 *LANG* Provide a default value for the internationalization variables that are unset or null.
95000 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
95001 variables used to determine the values of locale categories.)

95002 *LC_ALL* If set to a non-empty string value, override the values of all the other
95003 internationalization variables.

95004 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
95005 characters (for example, single-byte as opposed to multi-byte characters in
95006 arguments).

95007 *LC_MESSAGES*
95008 Determine the locale that should be used to affect the format and contents of
95009 diagnostic messages written to standard error.

95010 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

95011 **ASYNCHRONOUS EVENTS**
95012 Default.

95013 **STDOUT**
95014 When the **–l** option is not specified, the standard output shall not be used.

95015 When the **–l** option is specified, the symbolic name of each signal shall be written in the
95016 following format:

95017 `"%s%c", <signal_name>, <separator>`

95018 where the <*signal_name*> is in uppercase, without the **SIG** prefix, and the <*separator*> shall be
95019 either a <newline> or a <space>. For the last signal written, <*separator*> shall be a <newline>.

95020 When both the **–l** option and *exit_status* operand are specified, the symbolic name of the
95021 corresponding signal shall be written in the following format:

95022 `"%s\n", <signal_name>`

95023 **STDERR**
95024 The standard error shall be used only for diagnostic messages.

95025 **OUTPUT FILES**
95026 None.

95027 **EXTENDED DESCRIPTION**
95028 None.

95029 **EXIT STATUS**
95030 The following exit values shall be returned:

95031 0 At least one matching process was found for each *pid* operand, and the specified signal was
95032 successfully processed for at least one matching process.

95033 >0 An error occurred.

95034 **CONSEQUENCES OF ERRORS**
95035 Default.

95036 **APPLICATION USAGE**
95037 Process numbers can be found by using *ps*.

95038 The job control job ID notation is not required to work as expected when *kill* is operating in its
95039 own utility execution environment. In either of the following examples:

95040 ```
nohup kill %1 &
```
95041 ```
system("kill %1");
```

95042 the *kill* operates in a different environment and does not share the shell's understanding of job
95043 numbers.

95044 **EXAMPLES**
95045 Any of the commands:

95046 ```
kill –9 100 –165
```
95047 ```
kill –s kill 100 –165
```

```
kill −s KILL 100 −165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

The System Interfaces volume of POSIX.1-2017 and this volume of POSIX.1-2017 do not require specific signal numbers for any *signal_names*. Even the *–signal_number* option provides symbolic (although numeric) names for signals. If a process is terminated by a signal, its exit status indicates the signal that killed it, but the exact values are not specified. The *kill* **–l** option, however, can be used to map decimal signal numbers and exit status values into the name of a signal. The following example reports the status of a terminated job:

```
job
stat=$?
if [ $stat −eq 0 ]
then
    echo job completed successfully.
elif [ $stat −gt 128 ]
then
    echo job terminated by signal SIG$(kill −l $stat).
else
    echo job terminated with error code $stat.
fi
```

To send the default signal to a process group (say 123), an application should use a command similar to one of the following:

```
kill −TERM −123
kill −− −123
```

RATIONALE

The **–l** option originated from the C shell, and is also implemented in the KornShell. The C shell output can consist of multiple output lines because the signal names do not always fit on a single line on some terminal screens. The KornShell output also included the implementation-defined signal numbers and was considered by the standard developers to be too difficult for scripts to parse conveniently. The specified output format is intended not only to accommodate the historical C shell output, but also to permit an entirely vertical or entirely horizontal listing on systems for which this is appropriate.

An early proposal invented the name SIGNULL as a *signal_name* for signal 0 (used by the System Interfaces volume of POSIX.1-2017 to test for the existence of a process without sending it a signal). Since the *signal_name* 0 can be used in this case unambiguously, SIGNULL has been removed.

An early proposal also required symbolic *signal_name*s to be recognized with or without the **SIG** prefix. Historical versions of *kill* have not written the **SIG** prefix for the **–l** option and have not recognized the **SIG** prefix on *signal_name*s. Since neither applications portability nor ease-of-use would be improved by requiring this extension, it is no longer required.

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, POSIX.1-2017 mandates that it is always considered the former by implementations that support the XSI option. It also requires that conforming applications always use the `"−−"` options terminator argument when specifying a process group, unless an option is also specified.

The **–s** option was added in response to international interest in providing some form of *kill* that

meets the Utility Syntax Guidelines.

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not understand how the shell has managed its job numbers.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent versions of the SYNOPSIS are turned into non-obsolescent features of the XSI option, corresponding to a similar change in the *trap* special built-in.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

lex — generate programs for lexical tasks (**DEVELOPMENT**)

SYNOPSIS

CD

```
lex [-t] [-n|-v] [file...]
```

DESCRIPTION

The *lex* utility shall generate C programs to be used in lexical processing of character input, and that can be used as an interface to *yacc*. The C programs shall be generated from *lex* source code and conform to the ISO C standard, without depending on any undefined, unspecified, or implementation-defined behavior, except in cases where the code is copied directly from the supplied source, or in cases that are documented by the implementation. Usually, the *lex* utility shall write the program it generates to the file **lex.yy.c**; the state of this file is unspecified if *lex* exits with a non-zero exit status. See the EXTENDED DESCRIPTION section for a complete description of the *lex* input language.

OPTIONS

The *lex* utility shall conform to XBD Section 12.2 (on page 216), except for Guideline 9.

The following options shall be supported:

−n Suppress the summary of statistics usually written with the **−v** option. If no table sizes are specified in the *lex* source code and the **−v** option is not specified, then **−n** is implied.

−t Write the resulting program to standard output instead of **lex.yy.c**.

−v Write a summary of *lex* statistics to the standard output. (See the discussion of *lex* table sizes in Definitions in lex (on page 2887).) If the **−t** option is specified and **−n** is not specified, this report shall be written to standard error. If table sizes are specified in the *lex* source code, and if the **−n** option is not specified, the **−v** option may be enabled.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If more than one such *file* is specified, all files shall be concatenated to produce a single *lex* program. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, or if a *file* operand is `'−'`. See INPUT FILES.

INPUT FILES

The input files shall be text files containing *lex* source code, as described in the EXTENDED DESCRIPTION section.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *lex*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

95158 *LC_COLLATE*
95159 Determine the locale for the behavior of ranges, equivalence classes, and multi-
95160 character collating elements within regular expressions. If this variable is not set to
95161 the POSIX locale, the results are unspecified.

95162 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
95163 characters (for example, single-byte as opposed to multi-byte characters in
95164 arguments and input files), and the behavior of character classes within regular
95165 expressions. If this variable is not set to the POSIX locale, the results are
95166 unspecified.

95167 *LC_MESSAGES*
95168 Determine the locale that should be used to affect the format and contents of
95169 diagnostic messages written to standard error.

95170 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

95171 **ASYNCHRONOUS EVENTS**
95172 Default.

95173 **STDOUT**
95174 If the **−t** option is specified, the text file of C source code output of *lex* shall be written to
95175 standard output.

95176 If the **−t** option is not specified:

95177 Implementation-defined informational, error, and warning messages concerning the
95178 contents of *lex* source code input shall be written to either the standard output or standard
95179 error.

95180 If the **−v** option is specified and the **−n** option is not specified, *lex* statistics shall also be
95181 written to either the standard output or standard error, in an implementation-defined
95182 format. These statistics may also be generated if table sizes are specified with a `'%'`
95183 operator in the *Definitions* section, as long as the **−n** option is not specified.

95184 **STDERR**
95185 If the **−t** option is specified, implementation-defined informational, error, and warning messages
95186 concerning the contents of *lex* source code input shall be written to the standard error.

95187 If the **−t** option is not specified:

95188 1. Implementation-defined informational, error, and warning messages concerning the
95189 contents of *lex* source code input shall be written to either the standard output or
95190 standard error.

95191 2. If the **−v** option is specified and the **−n** option is not specified, *lex* statistics shall also be
95192 written to either the standard output or standard error, in an implementation-defined
95193 format. These statistics may also be generated if table sizes are specified with a `'%'`
95194 operator in the *Definitions* section, as long as the **−n** option is not specified.

95195 **OUTPUT FILES**
95196 A text file containing C source code shall be written to **lex.yy.c**, or to the standard output if the **−t**
95197 option is present.

95198 **EXTENDED DESCRIPTION**
95199 Each input file shall contain *lex* source code, which is a table of regular expressions with
95200 corresponding actions in the form of C program fragments.

95201 When **lex.yy.c** is compiled and linked with the *lex* library (using the **−l l** operand with *c99*), the

95202 resulting program shall read character input from the standard input and shall partition it into
95203 strings that match the given expressions.

95204 When an expression is matched, these actions shall occur:

95205 The input string that was matched shall be left in *yytext* as a null-terminated string; *yytext*
95206 shall either be an external character array or a pointer to a character string. As explained in
95207 Definitions in lex (on page 2887), the type can be explicitly selected using the **%array** or
95208 **%pointer** declarations, but the default is implementation-defined.

95209 The external **int** *yyleng* shall be set to the length of the matching string.

95210 The expression's corresponding program fragment, or action, shall be executed.

95211 During pattern matching, *lex* shall search the set of patterns for the single longest possible
95212 match. Among rules that match the same number of characters, the rule given first shall be
95213 chosen.

95214 The general format of *lex* source shall be:

95215 *Definitions*
95216 **%%**
95217 *Rules*
95218 **%%**
95219 *User*Subroutines

95220 The first "%%" is required to mark the beginning of the rules (regular expressions and actions);
95221 the second "%%" is required only if user subroutines follow.

95222 Any line in the *Definitions* section beginning with a <blank> shall be assumed to be a C program
95223 fragment and shall be copied to the external definition area of the **lex.yy.c** file. Similarly,
95224 anything in the *Definitions* section included between delimiter lines containing only "%{" and
95225 "%}" shall also be copied unchanged to the external definition area of the **lex.yy.c** file.

95226 Any such input (beginning with a <blank> or within "%{" and "%}" delimiter lines) appearing
95227 at the beginning of the *Rules* section before any rules are specified shall be written to **lex.yy.c**
95228 after the declarations of variables for the *yylex*() function and before the first line of code in
95229 *yylex*(). Thus, user variables local to *yylex*() can be declared here, as well as application code to
95230 execute upon entry to *yylex*().

95231 The action taken by *lex* when encountering any input beginning with a <blank> or within "%{"
95232 and "%}" delimiter lines appearing in the *Rules* section but coming after one or more rules is
95233 undefined. The presence of such input may result in an erroneous definition of the *yylex*()
95234 function.

95235 C-language code in the input shall not contain C-language trigraphs. The C-language code
95236 within "%{" and "%}" delimiter lines shall not contain any lines consisting only of "%}", or
95237 only of "%%".

95238 **Definitions in lex**

95239 *Definitions* appear before the first "`%%`" delimiter. Any line in this section not contained between
95240 "`%{`" and "`%}`" lines and not beginning with a <blank> shall be assumed to define a *lex*
95241 substitution string. The format of these lines shall be:

95242 `name substitute`

95243 If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is
95244 undefined. The string *substitute* shall replace the string {*name*} when it is used in a rule. The *name*
95245 string shall be recognized in this context only when the braces are provided and when it does
95246 not appear within a bracket expression or within double-quotes.

95247 In the *Definitions* section, any line beginning with a <percent-sign> ('`%`') character and followed
95248 by an alphanumeric word beginning with either '`s`' or '`S`' shall define a set of start conditions.
95249 Any line beginning with a '`%`' followed by a word beginning with either '`x`' or '`X`' shall
95250 define a set of exclusive start conditions. When the generated scanner is in a `%s` state, patterns
95251 with no state specified shall be also active; in a `%x` state, such patterns shall not be active. The
95252 rest of the line, after the first word, shall be considered to be one or more <blank>-separated
95253 names of start conditions. Start condition names shall be constructed in the same way as
95254 definition names. Start conditions can be used to restrict the matching of regular expressions to
95255 one or more states as described in Regular Expressions in lex (on page 2888).

95256 Implementations shall accept either of the following two mutually-exclusive declarations in the
95257 *Definitions* section:

95258 **%array** Declare the type of *yytext* to be a null-terminated character array.

95259 **%pointer** Declare the type of *yytext* to be a pointer to a null-terminated character string.

95260 The default type of *yytext* is implementation-defined. If an application refers to *yytext* outside of
95261 the scanner source file (that is, via an **extern**), the application shall include the appropriate
95262 **%array** or **%pointer** declaration in the scanner source file.

95263 Implementations shall accept declarations in the *Definitions* section for setting certain internal
95264 table sizes. The declarations are shown in the following table.

95265 **Table 4-10** Table Size Declarations in *lex*

95266

Declaration	Description	Minimum Value
%**p** *n*	Number of positions	2 500
%**n** *n*	Number of states	500
%**a** *n*	Number of transitions	2 000
%**e** *n*	Number of parse tree nodes	1 000
%**k** *n*	Number of packed character classes	1 000
%**o** *n*	Size of the output array	3 000

95273 In the table, *n* represents a positive decimal integer, preceded by one or more <blank>
95274 characters. The exact meaning of these table size numbers is implementation-defined. The
95275 implementation shall document how these numbers affect the *lex* utility and how they are
95276 related to any output that may be generated by the implementation should limitations be
95277 encountered during the execution of *lex*. It shall be possible to determine from this output
95278 which of the table size values needs to be modified to permit *lex* to successfully generate tables
95279 for the input language. The values in the column Minimum Value represent the lowest values
95280 conforming implementations shall provide.

Rules in lex

The rules in *lex* source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

```
ERE action
ERE action
...
```

The extended regular expression (ERE) portion of a row shall be separated from *action* by one or more <blank> characters. A regular expression containing <blank> characters shall be recognized under one of the following conditions:

The entire expression appears within double-quotes.

The <blank> characters appear within double-quotes or square brackets.

Each <blank> is preceded by a <backslash> character.

User Subroutines in lex

Anything in the user subroutines section shall be copied to **lex.yy.c** following *yylex*( ).

Regular Expressions in lex

The *lex* utility shall support the set of extended regular expressions (see XBD Section 9.4, on page 188), with the following additions and exceptions to the syntax:

`"..."` Any string enclosed in double-quotes shall represent the characters within the double-quotes as themselves, except that <backslash>-escapes (which appear in the following table) shall be recognized. Any <backslash>-escape sequence shall be terminated by the closing quote. For example, `"\01""1"` represents a single string: the octal value 1 followed by the character `'1'`.

<state>r, *<state1,state2,...>r*
The regular expression *r* shall be matched only when the program is in one of the start conditions indicated by *state*, *state1*, and so on; see Actions in lex (on page 2890). (As an exception to the typographical conventions of the rest of this volume of POSIX.1-2017, in this case *<state>* does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition shall be recognized as such only at the beginning of a regular expression.

r/x The regular expression *r* shall be matched only if it is followed by an occurrence of regular expression *x* (*x* is the instance of trailing context, further defined below). The token returned in *yytext* shall only match *r*. If the trailing portion of *r* matches the beginning of *x*, the result is unspecified. The *r* expression cannot include further trailing context or the `'$'` (match-end-of-line) operator; *x* cannot include the `'^'` (match-beginning-of-line) operator, nor trailing context, nor the `'$'` operator. That is, only one occurrence of trailing context is allowed in a *lex* regular expression, and the `'^'` operator only can be used at the beginning of such an expression.

{*name*} When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, shall be replaced by the *substitute* value. The *substitute* value shall be treated in the extended regular expression as if it were enclosed in parentheses. No substitution shall occur if {*name*} occurs within a bracket expression or within double-quotes.

Within an ERE, a <backslash> character shall be considered to begin an escape sequence as specified in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in the following table shall be recognized.

A literal <newline> cannot occur within an ERE; the escape sequence `'\n'` can be used to represent a <newline>. A <newline> shall not be matched by a period operator.

Table 4-11 Escape Sequences in *lex*

Escape Sequence	Description	Meaning
`\`*digits*	A <backslash> character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <backslash> for each byte.
`\x`*digits*	A <backslash> character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the hexadecimal integer.
`\c`	A <backslash> character followed by any character not described in this table or in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`).	The character `'c'`, unchanged.

Note: If a `'\x'` sequence needs to be immediately followed by a hexadecimal digit character, a sequence such as `"\x1""1"` can be used, which represents a character containing the value 1, followed by the character `'1'`.

The order of precedence given to extended regular expressions for *lex* differs from that specified in XBD Section 9.4 (on page 188). The order of precedence for *lex* shall be as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context, and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

95363 **Table 4-12** ERE Precedence in *lex*

Extended Regular Expression	Precedence
collation-related bracket symbols	`[= =]  [: :]  [. .]`
escaped characters	`\<special character>`
bracket expression	`[ ]`
quoting	`"..."`
grouping	`( )`
definition	`{name}`
single-character RE duplication	`* + ?`
concatenation	
interval expression	`{m,n}`
alternation	`|`

95375 The ERE anchoring operators `'^'` and `'$'` do not appear in the table. With *lex* regular
95376 expressions, these operators are restricted in their use: the `'^'` operator can only be used at the
95377 beginning of an entire regular expression, and the `'$'` operator only at the end. The operators
95378 apply to the entire regular expression. Thus, for example, the pattern `"(^abc)|(def$)"` is
95379 undefined; it can instead be written as two separate rules, one with the regular expression
95380 `"^abc"` and one with `"def$"`, which share a common action via the special `'|'` action (see
95381 below). If the pattern were written `"^abc|def$"`, it would match either `"abc"` or `"def"` on a
95382 line by itself.

95383 Unlike the general ERE rules, embedded anchoring is not allowed by most historical *lex*
95384 implementations. An example of embedded anchoring would be for patterns such as
95385 `"(^| )foo( |$)"` to match `"foo"` when it exists as a complete word. This functionality can
95386 be obtained using existing *lex* features:

```
95387 ^foo/[ \n]       |
95388 " foo"/[ \n]     /* Found foo as a separate word. */
```

95389 Note also that `'$'` is a form of trailing context (it is equivalent to `"/\n"`) and as such cannot be
95390 used with regular expressions containing another instance of the operator (see the preceding
95391 discussion of trailing context).

95392 The additional regular expressions trailing-context operator `'/'` can be used as an ordinary
95393 character if presented within double-quotes, `"/"`; preceded by a <backslash>, `"\/"`; or within a
95394 bracket expression, `"[/]"`. The start-condition `'<'` and `'>'` operators shall be special only in a
95395 start condition at the beginning of a regular expression; elsewhere in the regular expression they
95396 shall be treated as ordinary characters.

95397 **Actions in lex**

95398 The action to be taken when an ERE is matched can be a C program fragment or the special
95399 actions described below; the program fragment can contain one or more C statements, and can
95400 also include special actions. The empty C statement `';'` shall be a valid action; any string in the
95401 **lex.yy.c** input that matches the pattern portion of such a rule is effectively ignored or skipped.
95402 However, the absence of an action shall not be valid, and the action *lex* takes in such a condition
95403 is undefined.

95404 The specification for an action, including C statements and special actions, can extend across
95405 several lines if enclosed in braces:

```
95406 ERE <one or more blanks> { program statement
95407                             program statement }
```

The program statements shall not contain unbalanced curly brace preprocessing tokens.

The default action when a string in the input to a **lex.yy.c** program is not matched by any expression shall be to copy the string to the output. Because the default behavior of a program generated by *lex* is to read the input and copy it to the output, a minimal *lex* source program that has just `"%%"` shall generate a C program that simply copies the input to the output unchanged.

Four special actions shall be available:

```
|    ECHO;    REJECT;    BEGIN
```

`|` The action `'|'` means that the action for the next rule is the action for this rule. Unlike the other three actions, `'|'` cannot be enclosed in braces or be <semicolon>-terminated; the application shall ensure that it is specified alone, with no other actions.

ECHO; Write the contents of the string *yytext* on the output.

REJECT; Usually only a single expression is matched by a given string in the input. **REJECT** means ``continue to the next expression that matches the current input'', and shall cause whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions `"xyz"` and `"xy"` and the input `"xyz"`, usually only the regular expression `"xyz"` would match. The next attempted match would start after **z.** If the last action in the `"xyz"` rule is **REJECT**, both this rule and the `"xy"` rule would be executed. The **REJECT** action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a **goto** to another part of *yylex*(). The use of **REJECT** may result in somewhat larger and slower scanners.

BEGIN The action:

```
BEGIN newstate;
```

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the *Definitions* section, the results are unspecified. The initial state is indicated by the digit `'0'` or the token **INITIAL**.

The functions or macros described below are accessible to user code included in the *lex* input. It is unspecified whether they appear in the C code output of *lex*, or are accessible only through the **–l l** operand to *c99* (the *lex* library).

int *yylex*(**void**)
Performs lexical analysis on the input; this is the primary function generated by the *lex* utility. The function shall return zero when the end of input is reached; otherwise, it shall return non-zero values (tokens) determined by the actions that are selected.

int *yymore*(**void**)
When called, indicates that when the next input string is recognized, it is to be appended to the current value of *yytext* rather than replacing it; the value in *yyleng* shall be adjusted accordingly.

int *yyless*(**int** *n*)
Retains *n* initial characters in *yytext*, NUL-terminated, and treats the remaining characters as if they had not been read; the value in *yyleng* shall be adjusted accordingly.

95451 **int** *input*(**void**)
95452 Returns the next character from the input, or zero on end-of-file. It shall obtain input from
95453 the stream pointer *yyin*, although possibly via an intermediate buffer. Thus, once scanning
95454 has begun, the effect of altering the value of *yyin* is undefined. The character read shall be
95455 removed from the input stream of the scanner without any processing by the scanner.

95456 **int** *unput*(**int** *c*)
95457 Returns the character `'c'` to the input; *yytext* and *yyleng* are undefined until the next
95458 expression is matched. The result of using *unput*( ) for more characters than have been input
95459 is unspecified.

95460 The following functions shall appear only in the *lex* library accessible through the **–l l** operand;
95461 they can therefore be redefined by a conforming application:

95462 **int** *yywrap*(**void**)
95463 Called by *yylex*( ) at end-of-file; the default *yywrap*( ) shall always return 1. If the application
95464 requires *yylex*( ) to continue processing with another source of input, then the application
95465 can include a function *yywrap*( ), which associates another file with the external variable
95466 **FILE** * *yyin* and shall return a value of zero.

95467 **int** *main*(**int** *argc*, **char** **argv*[ ])
95468 Calls *yylex*( ) to perform lexical analysis, then exits. The user code can contain *main*( ) to
95469 perform application-specific operations, calling *yylex*( ) as applicable.

95470 Except for *input*( ), *unput*( ), and *main*( ), all external and static names generated by *lex* shall begin
95471 with the prefix **yy** or **YY**.

95472 **EXIT STATUS**
95473 The following exit values shall be returned:

95474 0 Successful completion.

95475 >0 An error occurred.

95476 **CONSEQUENCES OF ERRORS**
95477 Default.

95478 **APPLICATION USAGE**
95479 Conforming applications are warned that in the *Rules* section, an ERE without an action is not
95480 acceptable, but need not be detected as erroneous by *lex*. This may result in compilation or
95481 runtime errors.

95482 The purpose of *input*( ) is to take characters off the input stream and discard them as far as the
95483 lexical analysis is concerned. A common use is to discard the body of a comment once the
95484 beginning of a comment is recognized.

95485 The *lex* utility is not fully internationalized in its treatment of regular expressions in the *lex*
95486 source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer
95487 interpret the regular expressions given in the *lex* source according to the environment specified
95488 when the lexical analyzer is executed, but this is not possible with the current *lex* technology.
95489 Furthermore, the very nature of the lexical analyzers produced by *lex* must be closely tied to the
95490 lexical requirements of the input language being described, which is frequently locale-specific
95491 anyway. (For example, writing an analyzer that is used for French text is not automatically
95492 useful for processing other languages.)

EXAMPLES

The following is an example of a *lex* program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* Need this for the call to atof() below. */
#include <math.h>
/* Need this for printf(), fopen(), and stdin below. */
#include <stdio.h>
%}

DIGIT    [0-9]
ID       [a-z][a-z0-9]*

%%

{DIGIT}+ {
    printf("An integer: %s (%d)\n", yytext,
        atoi(yytext));
    }

{DIGIT}+"."{DIGIT}*        {
    printf("A float: %s (%g)\n", yytext,
        atof(yytext));
    }

if|then|begin|end|procedure|function        {
    printf("A keyword: %s\n", yytext);
    }

{ID}    printf("An identifier: %s\n", yytext);

"+"|"-"|"*"|"/"        printf("An operator: %s\n", yytext);

"{"[^}\n]*"}"    /* Eat up one-line comments. */

[ \t\n]+        /* Eat up white space. */

.  printf("Unrecognized character: %s\n", yytext);

%%

int main(int argc, char *argv[])
{
    ++argv, --argc;  /* Skip over program name. */
    if (argc > 0)
        yyin = fopen(argv[0], "r");
    else
        yyin = stdin;

    yylex();
}
```

RATIONALE

Even though the **-c** option and references to the C language are retained in this description, *lex* may be generalized to other languages, as was done at one time for EFL, the Extended FORTRAN Language. Since the *lex* input specification is essentially language-independent, versions of this utility could be written to produce Ada, Modula-2, or Pascal code, and there are known historical implementations that do so.

The current description of *lex* bypasses the issue of dealing with internationalized EREs in the *lex* source code or generated lexical analyzer. If it follows the model used by *awk* (the source code is assumed to be presented in the POSIX locale, but input and output are in the locale specified by the environment variables), then the tables in the lexical analyzer produced by *lex* would interpret EREs specified in the *lex* source in terms of the environment variables specified when *lex* was executed. The desired effect would be to have the lexical analyzer interpret the EREs given in the *lex* source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current *lex* technology.

The description of octal and hexadecimal-digit escape sequences agrees with the ISO C standard use of escape sequences.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

There is no detailed output format specification. The observed behavior of *lex* under four different historical implementations was that none of these implementations consistently reported the line numbers for error and warning messages. Furthermore, there was a desire that *lex* be allowed to output additional diagnostic messages. Leaving message formats unspecified avoids these formatting questions and problems with internationalization.

Although the `%x` specifier for *exclusive* start conditions is not historical practice, it is believed to be a minor change to historical implementations and greatly enhances the usability of *lex* programs since it permits an application to obtain the expected functionality with fewer statements.

The **%array** and **%pointer** declarations were added as a compromise between historical systems. The System V-based *lex* copies the matched text to a *yytext* array. The *flex* program, supported in BSD and GNU systems, uses a pointer. In the latter case, significant performance improvements are available for some scanners. Most historical programs should require no change in porting from one system to another because the string being referenced is null-terminated in both cases. (The method used by *flex* in its case is to null-terminate the token in place by remembering the character that used to come right after the token and replacing it before continuing on to the next scan.) Multi-file programs with external references to *yytext* outside the scanner source file should continue to operate on their historical systems, but would require one of the new declarations to be considered strictly portable.

The description of EREs avoids unnecessary duplication of ERE details because their meanings within a *lex* ERE are the same as that for the ERE in this volume of POSIX.1-2017.

The reason for the undefined condition associated with text beginning with a <blank> or within "`%{`" and "`%}`" delimiter lines appearing in the *Rules* section is historical practice. Both the BSD and System V *lex* copy the indented (or enclosed) input in the *Rules* section (except at the beginning) to unreachable areas of the *yylex*( ) function (the code is written directly after a *break* statement). In some cases, the System V *lex* generates an error message or a syntax error, depending on the form of indented input.

The intention in breaking the list of functions into those that may appear in **lex.yy.c** *versus* those that only appear in **libl.a** is that only those functions in **libl.a** can be reliably redefined by a conforming application.

The descriptions of standard output and standard error are somewhat complicated because historical *lex* implementations chose to issue diagnostic messages to standard output (unless **−t** was given). POSIX.1-2017 allows this behavior, but leaves an opening for the more expected behavior of using standard error for diagnostics. Also, the System V behavior of writing the statistics when any table sizes are given is allowed, while BSD-derived systems can avoid it. The

95584 programmer can always precisely obtain the desired results by using either the **–t** or **–n** options.

95585 The OPERANDS section does not mention the use of – as a synonym for standard input; not all
95586 historical implementations support such usage for any of the *file* operands.

95587 A description of the *translation table* was deleted from early proposals because of its relatively
95588 low usage in historical applications.

95589 The change to the definition of the *input*() function that allows buffering of input presents the
95590 opportunity for major performance gains in some applications.

95591 The following examples clarify the differences between *lex* regular expressions and regular
95592 expressions appearing elsewhere in this volume of POSIX.1-2017. For regular expressions of the
95593 form `"r/x"`, the string matching *r* is always returned; confusion may arise when the beginning
95594 of *x* matches the trailing portion of *r*. For example, given the regular expression `"a*b/cc"` and
95595 the input `"aaabcc"`, *yytext* would contain the string `"aaab"` on this match. But given the
95596 regular expression `"x*/xy"` and the input `"xxxy"`, the token **xxx**, not **xx**, is returned by some
95597 implementations because **xxx** matches `"x*"`.

95598 In the rule `"ab*/bc"`, the `"b*"` at the end of *r* extends *r*'s match into the beginning of the
95599 trailing context, so the result is unspecified. If this rule were `"ab/bc"`, however, the rule
95600 matches the text `"ab"` when it is followed by the text `"bc"`. In this latter case, the matching of *r*
95601 cannot extend into the beginning of *x*, so the result is specified.

95602 **FUTURE DIRECTIONS**

95603 None.

95607 page 216)

95608 **CHANGE HISTORY**

95609 First released in Issue 2.

95610 **Issue 6**

95611 This utility is marked as part of the C-Language Development Utilities option.

95612 The obsolescent **–c** option is removed.

95613 The normative text is reworded to avoid use of the term ``must'' for application requirements.

95614 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/14 is applied, removing text describing
95615 behavior on systems with bytes consisting of more than eight bits.

95616 **Issue 7**

95617 Austin Group Interpretation 1003.1-2001 #190 is applied, clarifying the requirements for
95618 generated code to conform to the ISO C standard.

95619 Austin Group Interpretation 1003.1-2001 #191 is applied, clarifying the handling of C-language
95620 trigraphs and curly brace preprocessing tokens.

95621 SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not
95622 apply.

95623 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

95624 **NAME**

95625 link ‡'call*link*( ) function

95626 **SYNOPSIS**

95627 XSI
```
link file1 file2
```

95628 **DESCRIPTION**

95629 The *link* utility shall perform the function call:

95630
```
link(file1, file2);
```

95631 A user may need appropriate privileges to invoke the *link* utility.

95632 **OPTIONS**

95633 None.

95634 **OPERANDS**

95635 The following operands shall be supported:

95636 *file1* The pathname of an existing file.

95637 *file2* The pathname of the new directory entry to be created.

95638 **STDIN**

95639 Not used.

95640 **INPUT FILES**

95641 Not used.

95642 **ENVIRONMENT VARIABLES**

95643 The following environment variables shall affect the execution of *link*:

95644 *LANG* Provide a default value for the internationalization variables that are unset or null.
95645 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
95646 variables used to determine the values of locale categories.)

95647 *LC_ALL* If set to a non-empty string value, override the values of all the other
95648 internationalization variables.

95649 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
95650 characters (for example, single-byte as opposed to multi-byte characters in
95651 arguments).

95652 *LC_MESSAGES*
95653 Determine the locale that should be used to affect the format and contents of
95654 diagnostic messages written to standard error.

95655 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

95656 **ASYNCHRONOUS EVENTS**

95657 Default.

95658 **STDOUT**

95659 None.

95660 **STDERR**

95661 The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

XSH *link*( )

CHANGE HISTORY

First released in Issue 5.

95686 **NAME**

95687 ln ‡′link files

95688 **SYNOPSIS**

95689 `ln [-fs] [-L|-P] source_file target_file`

95690 `ln [-fs] [-L|-P] source_file... target_dir`

95691 **DESCRIPTION**

95692 In the first synopsis form, the *ln* utility shall create a new directory entry (link) at the destination
95693 path specified by the *target_file* operand. If the **−s** option is specified, a symbolic link shall be
95694 created for the file specified by the *source_file* operand. This first synopsis form shall be assumed
95695 when the final operand does not name an existing directory; if more than two operands are
95696 specified and the final is not an existing directory, an error shall result.

95697 In the second synopsis form, the *ln* utility shall create a new directory entry (link), or if the **−s**
95698 option is specified a symbolic link, for each file specified by a *source_file* operand, at a
95699 destination path in the existing directory named by *target_dir*.

95700 If the last operand specifies an existing file of a type not specified by the System Interfaces
95701 volume of POSIX.1-2017, the behavior is implementation-defined.

95702 The corresponding destination path for each *source_file* shall be the concatenation of the target
95703 directory pathname, a <slash> character if the target directory pathname did not end in a
95704 <slash>, and the last pathname component of the *source_file*. The second synopsis form shall be
95705 assumed when the final operand names an existing directory.

95706 For each *source_file*:

95707 1. If the destination path exists and was created by a previous step, it is unspecified whether
95708 *ln* shall write a diagnostic message to standard error, do nothing more with the current
95709 *source_file*, and go on to any remaining *source_file*s; or will continue processing the current
95710 *source_file*. If the destination path exists:

95711 a. If the **−f** option is not specified, *ln* shall write a diagnostic message to standard
95712 error, do nothing more with the current *source_file*, and go on to any remaining
95713 *source_file*s.

95714 b. If the destination path names the same directory entry as the current *source_file ln*
95715 shall write a diagnostic message to standard error, do nothing more with the
95716 current *source_file*, and go on to any remaining *source_file*s.

95717 c. Actions shall be performed equivalent to the *unlink*() function defined in the
95718 System Interfaces volume of POSIX.1-2017, called using the destination path as the
95719 *path* argument. If this fails for any reason, *ln* shall write a diagnostic message to
95720 standard error, do nothing more with the current *source_file*, and go on to any
95721 remaining *source_file*s.

95722 2. If the **−s** option is specified, actions shall be performed equivalent to the *symlink*()
95723 function with *source_file* as the *path1* argument and the destination path as the *path2*
95724 argument. The *ln* utility shall do nothing more with *source_file* and shall go on to any
95725 remaining files.

95726 3. If *source_file* is a symbolic link:

95727 a. If the **−P** option is in effect, actions shall be performed equivalent to the *linkat*()
95728 function with *source_file* as the *path1* argument, the destination path as the *path2*
95729 argument, AT_FDCWD as the *fd1* and *fd2* arguments, and zero as the *flag*
95730 argument.

95731 b. If the **−L** option is in effect, actions shall be performed equivalent to the *linkat*()
95732 function with *source_file* as the *path1* argument, the destination path as the *path2*
95733 argument, AT_FDCWD as the *fd1* and *fd2* arguments, and
95734 AT_SYMLINK_FOLLOW as the *flag* argument.

95735 The *ln* utility shall do nothing more with *source_file* and shall go on to any remaining files.

95736 4. Actions shall be performed equivalent to the *link*() function defined in the System
95737 Interfaces volume of POSIX.1-2017 using *source_file* as the *path1* argument, and the
95738 destination path as the *path2* argument.

95739 **OPTIONS**

95740 The *ln* utility shall conform to XBD Section 12.2 (on page 216).

95741 The following options shall be supported:

95742 **−f** Force existing destination pathnames to be removed to allow the link.

95743 **−L** For each *source_file* operand that names a file of type symbolic link, create a (hard)
95744 link to the file referenced by the symbolic link.

95745 **−P** For each *source_file* operand that names a file of type symbolic link, create a (hard)
95746 link to the symbolic link itself.

95747 **−s** Create symbolic links instead of hard links. If the **−s** option is specified, the **−L** and
95748 **−P** options shall be silently ignored.

95749 Specifying more than one of the mutually-exclusive options **−L** and **−P** shall not be considered
95750 an error. The last option specified shall determine the behavior of the utility (unless the **−s**
95751 option causes it to be ignored).

95752 If the **−s** option is not specified and neither a **−L** nor a **−P** option is specified, it is
95753 implementation-defined which of the **−L** and **−P** options will be used as the default.

95754 **OPERANDS**

95755 The following operands shall be supported:

95756 *source_file* A pathname of a file to be linked. If the **−s** option is specified, no restrictions on the
95757 type of file or on its existence shall be made. If the **−s** option is not specified,
95758 whether a directory can be linked is implementation-defined.

95759 *target_file* The pathname of the new directory entry to be created.

95760 *target_dir* A pathname of an existing directory in which the new directory entries are created.

95761 **STDIN**

95762 Not used.

95763 **INPUT FILES**

95764 None.

95765 **ENVIRONMENT VARIABLES**

95766 The following environment variables shall affect the execution of *ln*:

95767 *LANG* Provide a default value for the internationalization variables that are unset or null.
95768 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
95769 variables used to determine the values of locale categories.)

95770 *LC_ALL* If set to a non-empty string value, override the values of all the other
95771 internationalization variables.

95772 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
95773 characters (for example, single-byte as opposed to multi-byte characters in
95774 arguments).

95775 *LC_MESSAGES*
95776 Determine the locale that should be used to affect the format and contents of
95777 diagnostic messages written to standard error.

95778 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

95779 **ASYNCHRONOUS EVENTS**
95780 Default.

95781 **STDOUT**
95782 Not used.

95783 **STDERR**
95784 The standard error shall be used only for diagnostic messages.

95785 **OUTPUT FILES**
95786 None.

95787 **EXTENDED DESCRIPTION**
95788 None.

95789 **EXIT STATUS**
95790 The following exit values shall be returned:

95791 0 All the specified files were linked successfully.

95792 >0 An error occurred.

95793 **CONSEQUENCES OF ERRORS**
95794 Default.

95795 **APPLICATION USAGE**
95796 None.

95797 **EXAMPLES**
95798 None.

95799 **RATIONALE**
95800 The CONSEQUENCES OF ERRORS section does not require *ln* **−f** *a b* to remove *b* if a
95801 subsequent link operation would fail.

95802 Some historic versions of *ln* (including the one specified by the SVID) unlink the destination file,
95803 if it exists, by default. If the mode does not permit writing, these versions prompt for
95804 confirmation before attempting the unlink. In these versions the **−f** option causes *ln* not to
95805 attempt to prompt for confirmation.

95806 This allows *ln* to succeed in creating links when the target file already exists, even if the file itself
95807 is not writable (although the directory must be). Early proposals specified this functionality.

95808 This volume of POSIX.1-2017 does not allow the *ln* utility to unlink existing destination paths by
95809 default for the following reasons:

95810 The *ln* utility has historically been used to provide locking for shell applications, a usage
95811 that is incompatible with *ln* unlinking the destination path by default. There was no
95812 corresponding technical advantage to adding this functionality.

This functionality gave *ln* the ability to destroy the link structure of files, which changes the historical behavior of *ln*.

This functionality is easily replicated with a combination of *rm* and *ln*.

It is not historical practice in many systems; BSD and BSD-derived systems do not support this behavior. Unfortunately, whichever behavior is selected can cause scripts written expecting the other behavior to fail.

It is preferable that *ln* perform in the same manner as the *link*( ) function, which does not permit the target to exist already.

This volume of POSIX.1-2017 retains the **−f** option to provide support for shell scripts depending on the SVID semantics. It seems likely that shell scripts would not be written to handle prompting by *ln* and would therefore have specified the **−f** option.

The **−f** option is an undocumented feature of many historical versions of the *ln* utility, allowing linking to directories. These versions require modification.

Early proposals of this volume of POSIX.1-2017 also required a **−i** option, which behaved like the **−i** options in *cp* and *mv*, prompting for confirmation before unlinking existing files. This was not historical practice for the *ln* utility and has been omitted.

The **−L** and **−P** options allow for implementing both common behaviors of the *ln* utility. Earlier versions of this standard did not specify these options and required the behavior now described for the **−L** option. Many systems by default or as an alternative provided a non-conforming *ln* utility with the behavior now described for the **−P** option. Since applications could not rely on *ln* following links in practice, the **−L** and **−P** options were added to specify the desired behavior for the application.

The **−L** and **−P** options are ignored when **−s** is specified in order to allow an alias to be created to alter the default behavior when creating hard links (for example, *alias ln='ln* **−L**'). They serve no purpose when **−s** is specified, since *source_file* is then just a string to be used as the contents of the created symbolic link and need not exist as a file.

The specification ensures that *ln* **a a** with or without the **−f** option will not unlink the file **a**. Earlier versions of this standard were unclear in this case.

FUTURE DIRECTIONS

None.

XSH *link*( ), *unlink*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The *ln* utility is updated to include symbolic link processing as defined in the IEEE P1003.2b draft standard.

Issue 7

Austin Group Interpretations 1003.1-2001 #164, #168, and #169 are applied.

SD5-XCU-ERN-27 is applied, adding a new paragraph to the RATIONALE.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The **−L** and **−P** options are added to make it implementation-defined whether the *ln* utility follows symbolic links.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0096 [136] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0113 [930] is applied.

NAME

locale ‡'get locale-specific information

SYNOPSIS

```
locale [-a|-m]
locale [-ck] name...
```

DESCRIPTION

The *locale* utility shall write information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a *public locale* is one provided by the implementation that is accessible to the application.

When *locale* is invoked without any arguments, it shall summarize the current locale environment for each locale category as determined by the settings of the environment variables defined in XBD Chapter 7 (on page 135).

When invoked with operands, it shall write values that have been assigned to the keywords in the locale categories, as follows:

Specifying a keyword name shall select the named keyword and the category containing that keyword.

Specifying a category name shall select the named category and all keywords in that category.

OPTIONS

The *locale* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−a Write information about all available public locales. The available locales shall include **POSIX**, representing the POSIX locale. The manner in which the implementation determines what other locales are available is implementation-defined.

−c Write the names of selected locale categories; see the STDOUT section. The **−c** option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the **−k** option.

−k Write the names and values of selected keywords. The implementation may omit values for some keywords; see the OPERANDS section.

−m Write names of available charmaps; see XBD Section 6.1 (on page 125).

OPERANDS

The following operand shall be supported:

name The name of a locale category as defined in XBD Chapter 7 (on page 135), the name of a keyword in a locale category, or the reserved name **charmap**. The named category or keyword shall be selected for output. If a single *name* represents both a locale category name and a keyword name in the current locale, the results are unspecified. Otherwise, both category and keyword names can be specified as *name* operands, in any sequence. It is implementation-defined whether any keyword values are written for the categories *LC_CTYPE* and *LC_COLLATE*.

95901 **STDIN**

95902 Not used.

95903 **INPUT FILES**

95904 None.

95905 **ENVIRONMENT VARIABLES**

95906 The following environment variables shall affect the execution of *locale*:

95907 *LANG* Provide a default value for the internationalization variables that are unset or null.
95908 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
95909 variables used to determine the values of locale categories.)

95910 *LC_ALL* If set to a non-empty string value, override the values of all the other
95911 internationalization variables.

95912 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
95913 characters (for example, single-byte as opposed to multi-byte characters in
95914 arguments and input files).

95915 *LC_MESSAGES*
95916 Determine the locale that should be used to affect the format and contents of
95917 diagnostic messages written to standard error.

95918 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

95919 XSI The application shall ensure that the *LANG*, *LC_**, and *NLSPATH* environment variables specify
95920 the current locale environment to be written out; they shall be used if the **−a** option is not
95921 specified.

95922 **ASYNCHRONOUS EVENTS**

95923 Default.

95924 **STDOUT**

95925 The *LANG* variable shall be written first using the format:

95926 `"LANG=%s\n", <value>`

95927 If *LANG* is not set or is an empty string, the value is the empty string.

95928 If *locale* is invoked without any options or operands, the names and values of the *LC_**
95929 environment variables described in this volume of POSIX.1-2017 shall be written to the standard
95930 output, one variable per line, and each line using the following format. Only those variables set
95931 in the environment and not overridden by *LC_ALL* shall be written using this format:

95932 `"%s=%s\n", <variable_name>, <value>`

95933 The names of those *LC_** variables associated with locale categories defined in this volume of
95934 POSIX.1-2017 that are not set in the environment or are overridden by *LC_ALL* shall be written
95935 in the following format:

95936 `"%s=\"%s\"\n", <variable_name>, <implied value>`

95937 The <*implied value*> shall be the name of the locale that has been selected for that category by the
95938 implementation, based on the values in *LANG* and *LC_ALL*, as described in XBD Chapter 8 (on
95939 page 173).

95940 The <*value*> and <*implied value*> shown above shall be properly quoted for possible later reentry
95941 to the shell. The <*value*> shall not be quoted using double-quotes (so that it can be distinguished
95942 by the user from the <*implied value*> case, which always requires double-quotes).

The *LC_ALL* variable shall be written last, using the first format shown above. If it is not set, it shall be written as:

```
"LC_ALL=\n"
```

If any arguments are specified:

1. If the **−a** option is specified, the names of all the public locales shall be written, each in the following format:

   ```
   "%s\n", <locale name>
   ```

2. If the **−c** option is specified, the names of all selected categories shall be written, each in the following format:

   ```
   "%s\n", <category name>
   ```

   If keywords are also selected for writing (see following items), the category name output shall precede the keyword output for that category.

   If the **−c** option is not specified, the names of the categories shall not be written; only the keywords, as selected by the <*name*> operand, shall be written.

3. If the **−k** option is specified, the names and values of selected keywords shall be written. If a value is non-numeric and is not a compound keyword value, it shall be written in the following format:

   ```
   "%s=\"%s\"\n", <keyword name>, <keyword value>
   ```

   If a value is a non-numeric compound keyword value, it shall either be written in the format:

   ```
   "%s=\"%s\"\n", <keyword name>, <keyword value>
   ```

   where the <*keyword value*> is a single string of values separated by <semicolon> characters, or it shall be written in the format:

   ```
   "%s=%s\n", <keyword name>, <keyword value>
   ```

   where the <*keyword value*> is encoded as a set of strings, each enclosed in double-quotation-marks, separated by <semicolon> characters.

   If the keyword was **charmap**, the name of the charmap (if any) that was specified via the *localedef* **−f** option when the locale was created shall be written, with the word **charmap** as <*keyword name*>.

   If a value is numeric, it shall be written in one of the following formats:

   ```
   "%s=%d\n", <keyword name>, <keyword value>
   ```

   ```
   "%s=%c%o\n", <keyword name>, <escape character>, <keyword value>
   ```

   ```
   "%s=%cx%x\n", <keyword name>, <escape character>, <keyword value>
   ```

   where the <*escape character*> is that identified by the **escape_char** keyword in the current locale; see XBD Section 7.3 (on page 136).

   Compound keyword values (list entries) shall be separated in the output by <semicolon> characters. When included in keyword values, the <semicolon>, <backslash>, double-quote, and any control character shall be preceded (escaped) with the escape character.

4. If the **–k** option is not specified, selected keyword values shall be written, each in the following format:

   `"%s\n", <keyword value>`

   If the keyword was **charmap**, the name of the charmap (if any) that was specified via the *localedef* **–f** option when the locale was created shall be written.

5. If the **–m** option is specified, then a list of all available charmaps shall be written, each in the format:

   `"%s\n", <charmap>`

   where <*charmap*> is in a format suitable for use as the option-argument to the *localedef* **–f** option.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All the requested information was found and output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the *LANG* environment variable is not set or set to an empty value, or one of the *LC_** environment variables is set to an unrecognized value, the actual locales assumed (if any) are implementation-defined as described in XBD Chapter 8 (on page 173).

Implementations are not required to write out the actual values for keywords in the categories *LC_CTYPE* and *LC_COLLATE*; however, they must write out the categories (allowing an application to determine, for example, which character classes are available).

EXAMPLES

In the following examples, the assumption is that locale environment variables are set as follows:

```
LANG=locale_x
LC_COLLATE=locale_y
```

The command *locale* would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_COLLATE=locale_y
LC_TIME="locale_x"
LC_NUMERIC="locale_x"
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The order of presentation of the categories is not specified by this volume of POSIX.1-2017.

The command:

```
LC_ALL=POSIX locale -ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of *locale* to determine whether a user-supplied response is affirmative:

```
printf 'Prompt for response: '
read response
if printf "%s\n" "$response" | grep -- -Eq "$(locale yesexpr)"
then
    affirmative processing goes here
else
    non-affirmative processing goes here
fi
```

RATIONALE

The output for categories *LC_CTYPE* and *LC_COLLATE* has been made implementation-defined because there is a questionable value in having a shell script receive an entire array of characters. It is also difficult to return a logical collation description, short of returning a complete *localedef* source.

The **−m** option was included to allow applications to query for the existence of charmaps. The output is a list of the charmaps (implementation-supplied and user-supplied, if any) on the system.

The **−c** option was included for readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the **−k** option.

The **charmap** keyword, which returns the name of the charmap (if any) that was used when the current locale was created, was included to allow applications needing the information to retrieve it.

According to XBD Section 6.1 (on page 125), the standard requires that all supported locales must have the same encoding for <period> and <slash>, because these two characters are used within the locale-independent pathname resolution sequence. Therefore, it would be an error if *locale* **−a** listed both ASCII and EBCDIC-based locales, since those two encodings do not share the same representation for either <period> or <slash>. Any system that supports both environments would be expected to provide two POSIX locales, one in either codeset, where only the locales appropriate to the current environment can be visible at a time. In an XSI-compliant implementation, the *dd* utility is the only portable means for performing conversions between the two character sets.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0097 [291] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0114 [941] is applied.

NAME

localedef — define locale environment

SYNOPSIS

```
localedef [−c] [−f charmap] [−i sourcefile] [−u code_set_name] name
```

DESCRIPTION

The *localedef* utility shall convert source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables defined in XBD Chapter 7 (on page 135). It is implementation-defined whether users have the capability to create new locales, in addition to those supplied by the implementation. If the symbolic constant POSIX2_LOCALEDEF is defined, the system supports
XSI the creation of new locales. On XSI-conformant systems, the symbolic constant POSIX2_LOCALEDEF shall be defined.

The utility shall read source definitions for one or more locale categories belonging to the same locale from the file named in the **−i** option (if specified) or from standard input.

The *name* operand identifies the target locale. The utility shall support the creation of *public*, or generally accessible locales, as well as *private*, or restricted-access locales. Implementations may restrict the capability to create or modify public locales to users with appropriate privileges.

Each category source definition shall be identified by the corresponding environment variable name and terminated by an **END** *category-name* statement. The following categories shall be supported. In addition, the input may contain source for implementation-defined categories.

LC_CTYPE Defines character classification and case conversion.

LC_COLLATE
Defines collation rules.

LC_MONETARY
Defines the format and symbols used in formatting of monetary information.

LC_NUMERIC
Defines the decimal delimiter, grouping, and grouping symbol for non-monetary numeric editing.

LC_TIME Defines the format and content of date and time information.

LC_MESSAGES
Defines the format and values of affirmative and negative responses.

OPTIONS

The *localedef* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−c Create permanent output even if warning messages have been issued.

−f *charmap* Specify the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. The format of the *charmap* is described in XBD Section 6.4 (on page 129). The application shall ensure that this option is specified if symbolic names (other than collating symbols defined in a **collating-symbol** keyword) are used. If the **−f** option is not present, an implementation-defined character mapping shall be used.

−i *inputfile* The pathname of a file containing the source definitions. If this option is not present, source definitions shall be read from standard input. The format of the *inputfile* is described in XBD Section 7.3 (on page 136).

96127 **−u** *code_set_name*

96128 Specify the name of a codeset used as the target mapping of character symbols and
96129 collating element symbols whose encoding values are defined in terms of the
96130 ISO/IEC 10646-1: 2000 standard position constant values.

96131 **OPERANDS**

96132 The following operand shall be supported:

96133 *name* Identifies the locale; see XBD Chapter 7 (on page 135) for a description of the use of
96134 this name. If the name contains one or more <slash> characters, *name* shall be
96135 interpreted as a pathname where the created locale definitions shall be stored. If
96136 *name* does not contain any <slash> characters, the interpretation of the name is
96137 implementation-defined and the locale shall be public. The ability to create public
96138 locales in this way may be restricted to users with appropriate privileges. (As a
96139 consequence of specifying one *name*, although several categories can be processed
96140 in one execution, only categories belonging to the same locale can be processed.)

96141 **STDIN**

96142 Unless the **−i** option is specified, the standard input shall be a text file containing one or more
96143 locale category source definitions, as described in XBD Section 7.3 (on page 136). When lines are
96144 continued using the escape character mechanism, there is no limit to the length of the
96145 accumulated continued line.

96146 **INPUT FILES**

96147 The character set mapping file specified as the *charmap* option-argument is described in XBD
96148 Section 6.4 (on page 129). If a locale category source definition contains a **copy** statement, as
96149 defined in XBD Chapter 7 (on page 135), and the **copy** statement names a valid, existing locale,
96150 then *localedef* shall behave as if the source definition had contained a valid category source
96151 definition for the named locale.

96152 **ENVIRONMENT VARIABLES**

96153 The following environment variables shall affect the execution of *localedef*:

96154 *LANG* Provide a default value for the internationalization variables that are unset or null.
96155 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
96156 variables used to determine the values of locale categories.)

96157 *LC_ALL* If set to a non-empty string value, override the values of all the other
96158 internationalization variables.

96159 *LC_COLLATE*

96160 (This variable has no affect on *localedef*; the POSIX locale is used for this category.)

96161 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
96162 characters (for example, single-byte as opposed to multi-byte characters in
96163 arguments and input files). This variable has no affect on the processing of *localedef*
96164 input data; the POSIX locale is used for this purpose, regardless of the value of this
96165 variable.

96166 *LC_MESSAGES*

96167 Determine the locale that should be used to affect the format and contents of
96168 diagnostic messages written to standard error.

96169 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

96170 **ASYNCHRONOUS EVENTS**

96171 Default.

96172 **STDOUT**

96173 The utility shall report all categories successfully processed, in an unspecified format.

96174 **STDERR**

96175 The standard error shall be used only for diagnostic messages.

96176 **OUTPUT FILES**

96177 The format of the created output is unspecified. If the *name* operand does not contain a <slash>,
96178 the existence of an output file for the locale is unspecified.

96179 **EXTENDED DESCRIPTION**

96180 When the **−u** option is used, the *code_set_name* option-argument shall be interpreted as an
96181 implementation-defined name of a codeset to which the ISO/IEC 10646-1: 2000 standard
96182 position constant values shall be converted via an implementation-defined method. Both the
96183 ISO/IEC 10646-1: 2000 standard position constant values and other formats (decimal,
96184 hexadecimal, or octal) shall be valid as encoding values within the *charmap* file. The codeset
96185 represented by the implementation-defined name can be any codeset that is supported by the
96186 implementation.

96187 When conflicts occur between the *charmap* specification of <*code_set_name*>, <*mb_cur_max*>, or
96188 <*mb_cur_min*> and the implementation-defined interpretation of these respective items for the
96189 codeset represented by the **−u** option-argument *code_set_name*, the result is unspecified.

96190 When conflicts occur between the *charmap* encoding values specified for symbolic names of
96191 characters of the portable character set and the implementation-defined assignment of character
96192 encoding values, the result is unspecified.

96193 If a non-printable character in the *charmap* has a width specified that is not **−1**, the result will be
96194 undefined.

96195 **EXIT STATUS**

96196 The following exit values shall be returned:

96197 0 No errors occurred and the locales were successfully created.

96198 1 Warnings occurred and the locales were successfully created.

96199 2 The locale specification exceeded implementation limits or the coded character set or sets
96200 used were not supported by the implementation, and no locale was created.

96201 3 The capability to create new locales is not supported by the implementation.

96202 >3 Warnings or errors occurred and no output was created.

96203 **CONSEQUENCES OF ERRORS**

96204 If an error is detected, no permanent output shall be created.

96205 If warnings occur, permanent output shall be created if the **−c** option was specified. The
96206 following conditions shall cause warning messages to be issued:

96207 If a symbolic name not found in the *charmap* file is used for the descriptions of the
96208 *LC_CTYPE* or *LC_COLLATE* categories (for other categories, this shall be an error
96209 condition).

96210 If the number of operands to the **order** keyword exceeds the {COLL_WEIGHTS_MAX}
96211 limit.

If optional keywords not supported by the implementation are present in the source.

Other implementation-defined conditions may also cause warnings.

APPLICATION USAGE

The *charmap* definition is optional, and is contained outside the locale definition. This allows both completely self-defined source files, and generic sources (applicable to more than one codeset). To aid portability, all *charmap* definitions must use the same symbolic names for the portable character set. As explained in XBD Section 6.4 (on page 129), it is implementation-defined whether or not users or applications can provide additional character set description files. Therefore, the **−f** option might be operable only when an implementation-defined *charmap* is named.

EXAMPLES

None.

RATIONALE

The output produced by the *localedef* utility is implementation-defined. The *name* operand is used to identify the specific locale. (As a consequence, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The **−u** option is added, as specified in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/15 is applied, rewording text in the OPERANDS section describing the ability to create public locales.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/16 is applied, making the text consistent with the descriptions of **WIDTH** and **WIDTH_DEFAULT** in the Base Definitions volume of POSIX.1-2017.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

96246 **NAME**

96247 logger ‡'log messages

96248 **SYNOPSIS**

96249 `logger` *`string`*`...`

96250 **DESCRIPTION**

96251 The *logger* utility saves a message, in an unspecified manner and format, containing the *string*
96252 operands provided by the user. The messages are expected to be evaluated later by personnel
96253 performing system administration tasks.

96254 It is implementation-defined whether messages written in locales other than the POSIX locale
96255 are effective.

96256 **OPTIONS**

96257 None.

96258 **OPERANDS**

96259 The following operand shall be supported:

96260 *string* One of the string arguments whose contents are concatenated together, in the order
96261 specified, separated by single <space> characters.

96262 **STDIN**

96263 Not used.

96264 **INPUT FILES**

96265 None.

96266 **ENVIRONMENT VARIABLES**

96267 The following environment variables shall affect the execution of *logger*:

96268 *LANG* Provide a default value for the internationalization variables that are unset or null.
96269 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
96270 variables used to determine the values of locale categories.)

96271 *LC_ALL* If set to a non-empty string value, override the values of all the other
96272 internationalization variables.

96273 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
96274 characters (for example, single-byte as opposed to multi-byte characters in
96275 arguments).

96276 *LC_MESSAGES*
96277 Determine the locale that should be used to affect the format and contents of
96278 diagnostic messages written to standard error. (This means diagnostics from *logger*
96279 to the user or application, not diagnostic messages that the user is sending to the
96280 system administrator.)

96281 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

96282 **ASYNCHRONOUS EVENTS**

96283 Default.

96284 **STDOUT**

96285 Not used.

96286 **STDERR**

96287 The standard error shall be used only for diagnostic messages.

96288 **OUTPUT FILES**

96289 Unspecified.

96290 **EXTENDED DESCRIPTION**

96291 None.

96292 **EXIT STATUS**

96293 The following exit values shall be returned:

96294 0 Successful completion.

96295 >0 An error occurred.

96296 **CONSEQUENCES OF ERRORS**

96297 Default.

96298 **APPLICATION USAGE**

96299 This utility allows logging of information for later use by a system administrator or programmer
96300 in determining why non-interactive utilities have failed. The locations of the saved messages,
96301 their format, and retention period are all unspecified. There is no method for a conforming
96302 application to read messages, once written.

96303 **EXAMPLES**

96304 A batch application, running non-interactively, tries to read a configuration file and fails; it may
96305 attempt to notify the system administrator with:

96306
```
logger myname: unable to read file foo. [timestamp]
```

96307 **RATIONALE**

96308 The standard developers believed strongly that some method of alerting administrators to errors
96309 was necessary. The obvious example is a batch utility, running non-interactively, that is unable to
96310 read its configuration files or that is unable to create or write its results file. However, the
96311 standard developers did not wish to define the format or delivery mechanisms as they have
96312 historically been (and will probably continue to be) very system-specific, as well as involving
96313 functionality clearly outside the scope of this volume of POSIX.1-2017.

96314 The text with *LC_MESSAGES* about diagnostic messages means diagnostics from *logger* to the
96315 user or application, not diagnostic messages that the user is sending to the system administrator.

96316 Multiple *string* arguments are allowed, similar to *echo*, for ease-of-use.

96317 Like the utilities *mailx* and *lp*, *logger* is admittedly difficult to test. This was not deemed sufficient
96318 justification to exclude these utilities from this volume of POSIX.1-2017. It is also arguable that
96319 they are, in fact, testable, but that the tests themselves are not portable.

96320 **FUTURE DIRECTIONS**

96321 None.

96322 **SEE ALSO**

96323 *lp*, *mailx*, *write*

96324 XBD Chapter 8 (on page 173)

96325 **CHANGE HISTORY**

96326 First released in Issue 4.

96327 **Issue 7**
96328 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

96329 **NAME**

96330 logname — return the user's login name

96331 **SYNOPSIS**

96332 `logname`

96333 **DESCRIPTION**

96334 The *logname* utility shall write the user's login name to standard output. The login name shall be
96335 the string that would be returned by the *getlogin*() function defined in the System Interfaces
96336 volume of POSIX.1-2017. Under the conditions where the *getlogin*() function would fail, the
96337 *logname* utility shall write a diagnostic message to standard error and exit with a non-zero exit
96338 status.

96339 **OPTIONS**

96340 None.

96341 **OPERANDS**

96342 None.

96343 **STDIN**

96344 Not used.

96345 **INPUT FILES**

96346 None.

96347 **ENVIRONMENT VARIABLES**

96348 The following environment variables shall affect the execution of *logname*:

96349 *LANG* Provide a default value for the internationalization variables that are unset or null.
96350 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
96351 variables used to determine the values of locale categories.)

96352 *LC_ALL* If set to a non-empty string value, override the values of all the other
96353 internationalization variables.

96354 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
96355 characters (for example, single-byte as opposed to multi-byte characters in
96356 arguments).

96357 *LC_MESSAGES*
96358 Determine the locale that should be used to affect the format and contents of
96359 diagnostic messages written to standard error.

96360 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

96361 **ASYNCHRONOUS EVENTS**

96362 Default.

96363 **STDOUT**

96364 The *logname* utility output shall be a single line consisting of the user's login name:

96365 `"%s\n", <login name>`

96366 **STDERR**

96367 The standard error shall be used only for diagnostic messages.

96368 **OUTPUT FILES**

96369 None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *logname* utility explicitly ignores the *LOGNAME* environment variable because environment changes could produce erroneous results.

EXAMPLES

None.

RATIONALE

The **passwd** file is not listed as required because the implementation may have other means of mapping login names.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

96394 **NAME**

96395 lp ‡'send files to a printer

96396 **SYNOPSIS**

96397 `lp [-c] [-d dest] [-n copies] [-msw] [-o option]... [-t title] [file...]`

96398 **DESCRIPTION**

96399 The *lp* utility shall copy the input files to an output destination in an unspecified manner. The
96400 default output destination should be to a hardcopy device, such as a printer or microfilm
96401 recorder, that produces non-volatile, human-readable documents. If such a device is not
96402 available to the application, or if the system provides no such device, the *lp* utility shall exit with
96403 a non-zero exit status.

96404 The actual writing to the output device may occur some time after the *lp* utility successfully
96405 exits. During the portion of the writing that corresponds to each input file, the implementation
96406 shall guarantee exclusive access to the device.

96407 The *lp* utility shall associate a unique *request ID* with each request.

96408 Normally, a banner page is produced to separate and identify each print job. This page may be
96409 suppressed by implementation-defined conditions, such as an operator command or one of the
96410 **−o** *option* values.

96411 **OPTIONS**

96412 The *lp* utility shall conform to XBD Section 12.2 (on page 216).

96413 The following options shall be supported:

96414 **−c** Exit only after further access to any of the input files is no longer required. The
96415 application can then safely delete or modify the files without affecting the output
96416 operation. Normally, files are not copied, but are linked whenever possible. If the
96417 **−c** option is not given, then the user should be careful not to remove any of the
96418 files before the request has been printed in its entirety. It should also be noted that
96419 in the absence of the **−c** option, any changes made to the named files after the
96420 request is made but before it is printed may be reflected in the printed output. On
96421 some implementations, **−c** may be on by default.

96422 **−d** *dest* Specify a string that names the destination (*dest*). If *dest* is a printer, the request
96423 shall be printed only on that specific printer. If *dest* is a class of printers, the request
96424 shall be printed on the first available printer that is a member of the class. Under
96425 certain conditions (printer unavailability, file space limitation, and so on), requests
96426 for specific destinations need not be accepted. Destination names vary between
96427 systems.

96428 If **−d** is not specified, and neither the *LPDEST* nor *PRINTER* environment variable
96429 is set, an unspecified destination is used. The **−d** *dest* option shall take precedence
96430 over *LPDEST*, which in turn shall take precedence over *PRINTER*. Results are
96431 undefined when *dest* contains a value that is not a valid destination name.

96432 **−m** Send mail (see *mailx*) after the files have been printed. By default, no mail is sent
96433 upon normal completion of the print request.

96434 **−n** *copies* Write *copies* number of copies of the files, where *copies* is a positive decimal integer.
96435 The methods for producing multiple copies and for arranging the multiple copies
96436 when multiple *file* operands are used are unspecified, except that each file shall be
96437 output as an integral whole, not interleaved with portions of other files.

96438 **−o** *option* Specify printer-dependent or class-dependent *option*s. Several such *option*s may be
96439 collected by specifying the **−o** option more than once.

96440 **−s** Suppress messages from *lp*.

96441 **−t** *title* Write *title* on the banner page of the output.

96442 **−w** Write a message on the user's terminal after the files have been printed. If the user
96443 is not logged in, then mail shall be sent instead.

96444 **OPERANDS**

96445 The following operand shall be supported:

96446 *file* A pathname of a file to be output. If no *file* operands are specified, or if a *file*
96447 operand is `'−'`, the standard input shall be used. If a *file* operand is used, but the
96448 **−c** option is not specified, the process performing the writing to the output device
96449 may have user and group permissions that differ from that of the process invoking
96450 *lp*.

96451 **STDIN**

96452 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.
96453 See the INPUT FILES section.

96454 **INPUT FILES**

96455 The input files shall be text files.

96456 **ENVIRONMENT VARIABLES**

96457 The following environment variables shall affect the execution of *lp*:

96458 *LANG* Provide a default value for the internationalization variables that are unset or null.
96459 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
96460 variables used to determine the values of locale categories.)

96461 *LC_ALL* If set to a non-empty string value, override the values of all the other
96462 internationalization variables.

96463 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
96464 characters (for example, single-byte as opposed to multi-byte characters in
96465 arguments and input files).

96466 *LC_MESSAGES*
96467 Determine the locale that should be used to affect the format and contents of
96468 diagnostic messages written to standard error and informative messages written to
96469 standard output.

96470 *LC_TIME* Determine the format and contents of date and time strings displayed in the *lp*
96471 banner page, if any.

96472 *LPDEST* Determine the destination. If the *LPDEST* environment variable is not set, the
96473 *PRINTER* environment variable shall be used. The **−d** *dest* option takes precedence
96474 over *LPDEST*. Results are undefined when **−d** is not specified and *LPDEST*
96475 contains a value that is not a valid destination name.

96476 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

96477 *PRINTER* Determine the output device or destination. If the *LPDEST* and *PRINTER*
96478 environment variables are not set, an unspecified output device is used. The **−d**
96479 *dest* option and the *LPDEST* environment variable shall take precedence over
96480 *PRINTER*. Results are undefined when **−d** is not specified, *LPDEST* is unset, and
96481 *PRINTER* contains a value that is not a valid device or destination name.

96482 *TZ* Determine the timezone used to calculate date and time strings displayed in the *lp*
96483 banner page, if any. If *TZ* is unset or null, an unspecified default timezone shall be
96484 used.

96485 **ASYNCHRONOUS EVENTS**
96486 Default.

96487 **STDOUT**
96488 The *lp* utility shall write a *request ID* to the standard output, unless **−s** is specified. The format of
96489 the message is unspecified. The request ID can be used on systems supporting the historical
96490 *cancel* and *lpstat* utilities.

96491 **STDERR**
96492 The standard error shall be used only for diagnostic messages.

96493 **OUTPUT FILES**
96494 None.

96495 **EXTENDED DESCRIPTION**
96496 None.

96497 **EXIT STATUS**
96498 The following exit values shall be returned:

96499 0 All input files were processed successfully.

96500 >0 No output device was available, or an error occurred.

96501 **CONSEQUENCES OF ERRORS**
96502 Default.

96503 **APPLICATION USAGE**
96504 The *pr* and *fold* utilities can be used to achieve reasonable formatting for the implementation's
96505 default page size.

96506 A conforming application can use one of the *file* operands only with the **−c** option or if the file is
96507 publicly readable and guaranteed to be available at the time of printing. This is because
96508 POSIX.1-2017 gives the implementation the freedom to queue up the request for printing at
96509 some later time by a different process that might not be able to access the file.

96510 **EXAMPLES**

96511 1. To print file *file*:

96512 `lp −c file`

96513 2. To print multiple files with headers:

96514 `pr file1 file2 | lp`

96515 **RATIONALE**
96516 The *lp* utility was designed to be a basic version of a utility that is already available in many
96517 historical implementations. The standard developers considered that it should be implementable
96518 simply as:

96519 `cat "$@" > /dev/lp`

96520 after appropriate processing of options, if that is how the implementation chose to do it and if
96521 exclusive access could be granted (so that two users did not write to the device simultaneously).
96522 Although in the future the standard developers may add other options to this utility, it should
96523 always be able to execute with no options or operands and send the standard input to an

unspecified output device.

This volume of POSIX.1-2017 makes no representations concerning the format of the printed output, except that it must be ``human-readable'' and ``non-volatile''. Thus, writing by default to a disk or tape drive or a display terminal would not qualify. (Such destinations are not prohibited when **−d** *dest*, *LPDEST*, or *PRINTER* are used, however.)

This volume of POSIX.1-2017 is worded such that a ``print job'' consisting of multiple input files, possibly in multiple copies, is guaranteed to print so that any one file is not intermixed with another, but there is no statement that all the files or copies have to print out together.

The **−c** option may imply a spooling operation, but this is not required. The utility can be implemented to wait until the printer is ready and then wait until it is finished. Because of that, there is no attempt to define a queuing mechanism (priorities, classes of output, and so on).

On some historical systems, the request ID reported on the STDOUT can be used to later cancel or find the status of a request using utilities not defined in this volume of POSIX.1-2017.

Although the historical System V *lp* and BSD *lpr* utilities have provided similar functionality, they used different names for the environment variable specifying the destination printer. Since the name of the utility here is *lp*, *LPDEST* (used by the System V *lp* utility) was given precedence over *PRINTER* (used by the BSD *lpr* utility). Since environments of users frequently contain one or the other environment variable, the *lp* utility is required to recognize both. If this was not done, many applications would send output to unexpected output devices when users moved from system to system.

Some have commented that *lp* has far too little functionality to make it worthwhile. Requests have proposed additional options or operands or both that added functionality. The requests included:

Wording *requiring* the output to be ``hardcopy''

A requirement for multiple printers

Options for supporting various page-description languages

Given that a compliant system is not required to even have a printer, placing further restrictions upon the behavior of the printer is not useful. Since hardcopy format is so application-dependent, it is difficult, if not impossible, to select a reasonable subset of functionality that should be required on all compliant systems.

The term *unspecified* is used in this section in lieu of *implementation-defined* as most known implementations would not be able to make definitive statements in their conformance documents; the existence and usage of printers is very dependent on how the system administrator configures each individual system.

Since the default destination, device type, queuing mechanisms, and acceptable forms of input are all unspecified, usage guidelines for what a conforming application can do are as follows:

Use the command in a pipeline, or with **−c**, so that there are no permission problems and the files can be safely deleted or modified.

Limit output to text files of reasonable line lengths and printable characters and include no device-specific formatting information, such as a page description language. The meaning of ``reasonable'' in this context can only be answered as a quality-of-implementation issue, but it should be apparent from historical usage patterns in the industry and the locale. The *pr* and *fold* utilities can be used to achieve reasonable formatting for the default page size of the implementation.

Alternatively, the application can arrange its installation in such a way that it requires the system administrator or operator to provide the appropriate information on *lp* options and environment variable values.

At a minimum, having this utility in this volume of POSIX.1-2017 tells the industry that conforming applications require a means to print output and provides at least a command name and *LPDEST* routing mechanism that can be used for discussions between vendors, application developers, and users. The use of ``should'' in the DESCRIPTION of *lp* clearly shows the intent of the standard developers, even if they cannot mandate that all systems (such as laptops) have printers.

This volume of POSIX.1-2017 does not specify what the ownership of the process performing the writing to the output device may be. If **−c** is not used, it is unspecified whether the process performing the writing to the output device has permission to read *file* if there are any restrictions in place on who may read *file* until after it is printed. Also, if **−c** is not used, the results of deleting *file* before it is printed are unspecified.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the requirement to associate a unique request ID, and the normal generation of a banner page is added.
- In the OPTIONS section:
  - ‡ḧéT–**d** *dest* description is expanded, but references to *lpstat* are removed.
  - ‡ḧéT–**m**, **−o**, **−s**, **−t**, and **−w** options are added.
- In the ENVIRONMENT VARIABLES section, *LC_TIME* may now affect the execution.
- The STDOUT section is added.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ls — list directory contents

SYNOPSIS

XSI
```
ls [-ikqrs] [-g lno ] [-A|-a] [-C|-m|-x|-1] \
    [-F|-p] [-H|-L] [-R|-d] [-S|-f|-t] [-c|-u] [file...]
```

DESCRIPTION

For each operand that names a file of a type other than directory or symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. For each operand that names a file of type directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information. Filenames beginning with a <period> (`'.'`) and any associated information shall not be written out unless explicitly referenced, the **−A** or **−a** option is supplied, or an implementation-defined condition causes them to be written. If one or more of the **−d**, **−F**, or **−l** options are specified, and neither the **−H** nor the **−L** option is specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. If none of the **−d**, **−F**, or **−l** options are specified, or the **−H** or **−L** options are specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information. In each case where the names of files contained within a directory are written, if the directory contains any symbolic links then *ls* shall evaluate the file information and file type to be those of the symbolic link itself, unless the **−L** option is specified.

If no operands are specified, *ls* shall behave as if a single operand of dot (`'.'`) had been specified. If more than one operand is specified, *ls* shall write non-directory operands first; it shall sort directory and non-directory operands separately according to the collating sequence in the current locale.

Whenever *ls* sorts filenames or pathnames according to the collating sequence in the current locale, if this collating sequence does not have a total ordering of all characters (see XBD Section 7.3.2, on page 147), then any filenames or pathnames that collate equally should be further compared byte-by-byte using the collating sequence for the POSIX locale.

The *ls* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *ls* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

OPTIONS

The *ls* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−A Write out all directory entries, including those whose names begin with a <period> (`'.'`) but excluding the entries dot and dot-dot (if they exist).

−C Write multi-text-column output with entries sorted down the columns, according to the collating sequence. The number of text columns and the column separator characters are unspecified, but should be adapted to the nature of the output device. This option disables long format output.

−F Do not follow symbolic links named as operands unless the **−H** or **−L** options are specified. Write a <slash> (`'/'`) immediately after each pathname that is a directory, an <asterisk> (`'*'`) after each that is executable, a <vertical-line> (`'|'`) after each that is a FIFO, and an at-sign (`'@'`) after each that is a symbolic link. For other file types, other symbols may be written.

96649 **−H** Evaluate the file information and file type for symbolic links specified on the
96650 command line to be those of the file referenced by the link, and not the link itself;
96651 however, *ls* shall write the name of the link itself and not the file referenced by the
96652 link.

96653 **−L** Evaluate the file information and file type for all symbolic links (whether named
96654 on the command line or encountered in a file hierarchy) to be those of the file
96655 referenced by the link, and not the link itself; however, *ls* shall write the name of
96656 the link itself and not the file referenced by the link. When **−L** is used with **−l**, write
96657 the contents of symbolic links in the long format (see the STDOUT section).

96658 **−R** Recursively list subdirectories encountered. When a symbolic link to a directory is
96659 encountered, the directory shall not be recursively listed unless the **−L** option is
96660 specified. The use of **−R** with **−d** or **−f** produces unspecified results.

96661 **−S** Sort with the primary key being file size (in decreasing order) and the secondary
96662 key being filename in the collating sequence (in increasing order).

96663 **−a** Write out all directory entries, including those whose names begin with a <period>
96664 (`'.'`).

96665 **−c** Use time of last modification of the file status information (see XBD **<sys/stat.h>**)
96666 instead of last modification of the file itself for sorting (**−t**) or writing (**−l**).

96667 **−d** Do not follow symbolic links named as operands unless the **−H** or **−L** options are
96668 specified. Do not treat directories differently than other types of files. The use of **−d**
96669 with **−R** or **−f** produces unspecified results.

96670 **−f** List the entries in directory operands in the order they appear in the directory. The
96671 behavior for non-directory operands is unspecified. This option shall turn on **−a**.
96672 When **−f** is specified, any occurrences of the **−r**, **−S**, and **−t** options shall be ignored
96673 XSI and any occurrences of the **−A**, **−g**, **−l**, **−n**, **−o**, and **−s** options may be ignored. The
96674 use of **−f** with **−R** or **−d** produces unspecified results.

96675 XSI **−g** Turn on the **−l** (ell) option, but disable writing the file's owner name or number.
96676 Disable the **−C**, **−m**, and **−x** options.

96677 **−i** For each file, write the file's file serial number (see *stat*( ) in the System Interfaces
96678 volume of POSIX.1-2017).

96679 **−k** Set the block size for the **−s** option and the per-directory block count written for
96680 XSI the **−l**, **−n**, **−s**, **−g**, and **−o** options (see the STDOUT section) to 1 024 bytes.

96681 **−l** (The letter ell.) Do not follow symbolic links named as operands unless the **−H** or
96682 **−L** options are specified. Write out in long format (see the STDOUT section).
96683 Disable the **−C**, **−m**, and **−x** options.

96684 **−m** Stream output format; list pathnames across the page, separated by a <comma>
96685 character followed by a <space> character. Use a <newline> character as the list
96686 terminator and after the separator sequence when there is not room on a line for
96687 the next list entry. This option disables long format output.

96688 **−n** Turn on the **−l** (ell) option, but when writing the file's owner or group, write the
96689 file's numeric UID or GID rather than the user or group name, respectively. Disable
96690 the **−C**, **−m**, and **−x** options.

96691 XSI **−o** Turn on the **−l** (ell) option, but disable writing the file's group name or number.
96692 Disable the **−C**, **−m**, and **−x** options.

96693 **−p** Write a <slash> (`'/'`) after each filename if that file is a directory.

96694 **−q** Force each instance of non-printable filename characters and <tab> characters to be
96695 written as the <question-mark> (`'?'`) character. Implementations may provide this
96696 option by default if the output is to a terminal device.

96697 **−r** Reverse the order of the sort to get reverse collating sequence oldest first, or
96698 smallest file size first depending on the other options given.

96699 **−s** Indicate the total number of file system blocks consumed by each file displayed. If
96700 the **−k** option is also specified, the block size shall be 1 024 bytes; otherwise, the
96701 block size is implementation-defined.

96702 **−t** Sort with the primary key being time modified (most recently modified first) and
96703 the secondary key being filename in the collating sequence. For a symbolic link,
96704 the time used as the sort key is that of the symbolic link itself, unless *ls* is
96705 evaluating its file information to be that of the file referenced by the link (see the
96706 **−H** and **−L** options).

96707 **−u** Use time of last access (see XBD **<sys/stat.h>**) instead of last modification of the file
96708 for sorting (**−t**) or writing (**−l**).

96709 **−x** The same as **−C**, except that the multi-text-column output is produced with entries
96710 sorted across, rather than down, the columns. This option disables long format
96711 output.

96712 **−1** (The numeric digit one.) Force output to be one entry per line. This option does
96713 XSI not disable long format output. (Long format output is enabled by **−g**, **−l** (ell), **−n**,
96714 XSI and **−o**; and disabled by **−C**, **−m**, and **−x**.)

96715 XSI If an option that enables long format output (**−g**, **−l** (ell), **−n**, and **−o**) is given with an option that
96716 disables long format output (**−C**, **−m**, and **−x**), this shall not be considered an error. The last of
96717 these options specified shall determine whether long format output is written.

96718 If **−R**, **−d**, or **−f** are specified, the results of specifying these mutually-exclusive options are
96719 specified by the descriptions of these options above. If more than one of any of the other options
96720 shown in the SYNOPSIS section in mutually-exclusive sets are given, this shall not be considered
96721 an error; the last option specified in each set shall determine the output.

96722 Note that if **−t** is specified, **−c** and **−u** are not only mutually-exclusive with each other, they are
96723 also mutually-exclusive with **−S** when determining sort order. But even if **−S** is specified after all
96724 occurrences of **−c**, **−t**, and **−u**, the last use of **−c** or **−u** determines the timestamp printed when
96725 producing long format output.

96726 **OPERANDS**

96727 The following operand shall be supported:

96728 *file* A pathname of a file to be written. If the file specified is not found, a diagnostic
96729 message shall be output on standard error.

96730 **STDIN**

96731 Not used.

96732 **INPUT FILES**

96733 None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ls*:

COLUMNS Determine the user's preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the *ls* utility shall calculate how many pathname text columns to write (see **−C**) based on the width provided. If *COLUMNS* is not set or invalid, an implementation-defined number of column positions shall be assumed, based on the implementation's knowledge of the output device. The column width chosen to write the names of files in any given directory shall be constant. Filenames shall not be truncated to fit into the multiple text-column output.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE Determine the locale for character collation information in determining the pathname collation sequence.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and which characters are defined as printable (character class **print**).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents for date and time strings written by *ls*.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone for date and time strings written by *ls*. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The default format shall be to list one entry per line to standard output; the exceptions are to terminals or when one of the **−C**, **−m**, or **−x** options is specified. If the output is to a terminal, the format is implementation-defined.

When **−m** is specified, the format used for the last element of the list shall be:

`"%s\n", <filename>`

The format used for each other element of the list shall be:

`"%s,%s", <filename>, <separator>`

where, if there is not room for the next element of the list to fit within the current line length, <*separator*> is a string containing an optional <space> character and a mandatory <newline> character; otherwise it is a single <space> character.

If the **−i** option is specified, the file's file serial number (see XBD **<sys/stat.h>**) shall be written in the following format before any other output for the corresponding entry:

96777 `%u ", <file serial number>`

96778 If the **–l** option is specified, the following information shall be written for files other than
96779 character special and block special files:

96780 `"%s %u %s %s %u %s %s\n", <file mode>, <number of links>,`
96781 `<owner name>, <group name>, <size>, <date and time>,`
96782 `<pathname>`

96783 If the **–l** option is specified, the following information shall be written for character special and
96784 block special files:

96785 `"%s %u %s %s %s %s %s\n", <file mode>, <number of links>,`
96786 `<owner name>, <group name>, <device info>, <date and time>,`
96787 `<pathname>`

96788 In both cases if the file is a symbolic link and the **–L** option is also specified, this information
96789 shall be for the file resolved from the symbolic link, except that the <*pathname*> field shall
96790 contain the pathname of the symbolic link itself. If the file is a symbolic link and the **–L** option is
96791 not specified, this information shall be about the link itself and the <*pathname*> field shall be of
96792 the form:

96793 `"%s -> %s", <pathname of link>, <contents of link>`

96794 XSI The **–n**, **–g**, and **–o** options use the same format as **–l**, but with omitted items and their
96795 associated <blank> characters. See the OPTIONS section.

96796 In both the preceding **–l** forms, if <*owner name*> or <*group name*> cannot be determined, or if **–n**
96797 is given, they shall be replaced with their associated numeric values using the format `%u`.

96798 The <*size*> field shall contain the value that would be returned for the file in the *st_size* field of
96799 **struct stat** (see XBD **<sys/stat.h>**). Note that for some file types this value is unspecified.

96800 The <*device info*> field shall contain implementation-defined information associated with the
96801 device in question.

96802 The <*date and time*> field shall contain the appropriate date and timestamp of when the file was
96803 last modified. In the POSIX locale, the field shall be the equivalent of the output of the following
96804 *date* command:

96805 `date "+%b %e %H:%M"`

96806 if the file has been modified in the last six months, or:

96807 `date "+%b %e %Y"`

96808 (where two <space> characters are used between `%e` and `%Y`) if the file has not been modified in
96809 the last six months or if the modification date is in the future, except that, in both cases, the final
96810 <newline> produced by *date* shall not be included and the output shall be as if the *date*
96811 command were executed at the time of the last modification date of the file rather than the
96812 current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format
96813 and order of presentation of this field may be used.

96814 If the pathname was specified as a *file* operand, it shall be written as specified.

96815 XSI The file mode written under the **–l**, **–n**, **–g**, and **–o** options shall consist of the following format:

96816 `"%c%s%s%s%s", <entry type>, <owner permissions>,`
96817 `<group permissions>, <other permissions>,`
96818 `<optional alternate access method flag>`

The <*optional alternate access method flag*> shall be the empty string if there is no alternate or additional access control method associated with the file; otherwise, it shall be a string containing a single printable character that is not a <blank>.

The <*entry type*> character shall describe the type of file, as follows:

`d` Directory.

`b` Block special file.

`c` Character special file.

`l` (ell) Symbolic link.

`p` FIFO.

– Regular file.

Implementations may add other characters to this list to represent other implementation-defined file types.

The next three fields shall be three characters each:

<*owner permissions*>
Permissions for the file owner class (see XBD Section 4.5, on page 108).

<*group permissions*>
Permissions for the file group class.

<*other permissions*>
Permissions for the file other class.

Each field shall have three character positions:

1. If `'r'`, the file is readable; if `'-'`, the file is not readable.
2. If `'w'`, the file is writable; if `'-'`, the file is not writable.
3. The first of the following that applies:

   `S` If in <*owner permissions*>, the file is not executable and set-user-ID mode is set. If in <*group permissions*>, the file is not executable and set-group-ID mode is set.

   `s` If in <*owner permissions*>, the file is executable and set-user-ID mode is set. If in <*group permissions*>, the file is executable and set-group-ID mode is set.

   XSI `T` If in <*other permissions*> and the file is a directory, search permission is not granted to others, and the restricted deletion flag is set.

   XSI `t` If in <*other permissions*> and the file is a directory, search permission is granted to others, and the restricted deletion flag is set.

   `x` The file is executable or the directory is searchable.

   – None of the attributes of `'S'`, `'s'`, `'T'`, `'t'`, or `'x'` applies.

   Implementations may add other characters to this list for the third character position. Such additions shall, however, be written in lowercase if the file is executable or searchable, and in uppercase if it is not.

XSI If any of the **–l**, **–n**, **–s**, **–g**, or **–o** options is specified, each list of files within the directory shall be preceded by a status line indicating the number of file system blocks occupied by files in the directory in 512-byte units if the **–k** option is not specified, or 1 024-byte units if the **–k** option is specified, rounded up to the next integral number of units, if necessary. In the POSIX locale, the

format shall be:

`"total %u\n", <number of units in the directory>`

If more than one directory, or a combination of non-directory files and directories are written, either as a result of specifying multiple operands, or the **–R** option, each list of files within a directory shall be preceded by:

`"\n%s:\n", <directory name>`

If this string is the first thing to be written, the first <newline> shall not be written. This output shall precede the number of units in the directory.

If the **–s** option is given, each file shall be written with the number of blocks used by the file. XSI Along with **–C**, **–1**, **–m**, or **–x**, the number and a <space> shall precede the filename; with **–l**, **–n**, **–g**, or **–o**, they shall precede each line describing a file.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Many implementations use the <equals-sign> (`'='`) to denote sockets bound to the file system for the **–F** option. Similarly, many historical implementations use the `'s'` character to denote sockets as the entry type characters for the **–l** option.

It is difficult for an application to use every part of the file modes field of *ls* **–l** in a portable manner. Certain file types and executable bits are not guaranteed to be exactly as shown, as implementations may have extensions. Applications can use this field to pass directly to a user printout or prompt, but actions based on its contents should generally be deferred, instead, to the *test* utility.

The output of *ls* (with the **–l** and related options) contains information that logically could be used by utilities such as *chmod* and *touch* to restore files to a known state. However, this information is presented in a format that cannot be used directly by those utilities or be easily translated into a format that can be used. A character has been added to the end of the permissions string so that applications at least have an indication that they may be working in an area they do not understand instead of assuming that they can translate the permissions string into something that can be used. Future versions or related documents may define one or more specific characters to be used based on different standard additional or alternative access control mechanisms.

As with many of the utilities that deal with filenames, the output of *ls* for multiple files or in one of the long listing formats must be used carefully on systems where filenames can contain embedded white space. Systems and system administrators should institute policies and user

training to limit the use of such filenames.

The number of disk blocks occupied by the file that it reports varies depending on underlying file system type, block size units reported, and the method of calculating the number of blocks. On some file system types, the number is the actual number of blocks occupied by the file (counting indirect blocks and ignoring holes in the file); on others it is calculated based on the file size (usually making an allowance for indirect blocks, but ignoring holes).

EXAMPLES

An example of a small directory tree being fully listed with *ls* –**laRF a** in the POSIX locale:

```
total 11
drwxr-xr-x   3 fox      prog          64 Jul  4 12:07 ./
drwxrwxrwx   4 fox      prog        3264 Jul  4 12:09 ../
drwxr-xr-x   2 fox      prog          48 Jul  4 12:07 b/
-rwxr--r--   1 fox      prog         572 Jul  4 12:07 foo*

a/b:
total 4
drwxr-xr-x   2 fox      prog          48 Jul  4 12:07 ./
drwxr-xr-x   3 fox      prog          64 Jul  4 12:07 ../
-rw-r--r--   1 fox      prog         700 Jul  4 12:07 bar
```

RATIONALE

Some historical implementations of the *ls* utility show all entries in a directory except dot and dot-dot when a superuser invokes *ls* without specifying the –**a** option. When ``normal'' users invoke *ls* without specifying –**a**, they should not see information about any files with names beginning with a <period> unless they were named as *file* operands.

Implementations are expected to traverse arbitrary depths when processing the –**R** option. The only limitation on depth should be based on running out of physical storage for keeping track of untraversed directories.

The –**1** (one) option was historically found in BSD and BSD-derived implementations only. It is required in this volume of POSIX.1-2017 so that conforming applications might ensure that output is one entry per line, even if the output is to a terminal.

The –**S** option was added in Issue 7, but had been provided by several implementations for many years. The description given in the standard documents historic practice, but does not match much of the documentation that described its behavior. Historical documentation typically described it as something like:

–**S** Sort by size (largest size first) instead of by name. Special character devices (listed last) are sorted by name.

even though the file type was never considered when sorting the output. Character special files do typically sort close to the end of the list because their file size on most implementations is zero. But they are sorted alphabetically with any other files that happen to have the same file size (zero), not sorted separately and added to the end.

This volume of POSIX.1-2017 is frequently silent about what happens when mutually-exclusive options are specified. Except for –**R**, –**d**, and –**f**, the *ls* utility is required to accept multiple options from each mutually-exclusive option set without treating them as errors and to use the behavior specified by the last option given in each mutually-exclusive set. Since *ls* is one of the most aliased commands, it is important that the implementation perform intuitively. For example, if the alias were:

```
alias ls="ls –C"
```

and the user typed *ls* –**1** (one), single-text-column output should result, not an error.

The –**g**, –**l** (ell), –**n**, and –**o** options are not mutually-exclusive options. They all enable long format output. They work together to determine whether the file's owner is written (no if –**g** is present), file's group is written (no if –**o** is present), and if the file's group or owner is written whether it is written as the name (default) or a string representation of the UID or GID number (if –**n** is present). The –**C**, –**m**, –**x**, and –**1** (one) are mutually-exclusive options and the first three of these disable long format output. The –**1** (one) option does not directly change whether or not long format output is enabled, but by overriding –**C**, –**m**, and –**x**, it can re-enable long format output that had been disabled by one of these options.

Earlier versions of this standard did not describe the BSD –**A** option (like –**a**, but dot and dot-dot are not written out). It has been added due to widespread implementation.

Implementations may make –**q** the default for terminals to prevent trojan horse attacks on terminals with special escape sequences. This is not required because:

> Some control characters may be useful on some terminals; for example, a system might write them as `"\001"` or `"^A"`.
>
> Special behavior for terminals is not relevant to applications portability.

An early proposal specified that the <*optional alternate access method flag*> had to be `'+'` if there was an alternate access method used on the file or <space> if there was not. This was changed to be <space> if there is not and a single printable character if there is. This was done for three reasons:

1. There are historical implementations using characters other than `'+'`.
2. There are implementations that vary this character used in that position to distinguish between various alternate access methods in use.
3. The standard developers did not want to preclude future specifications that might need a way to specify more than one alternate access method.

Nonetheless, implementations providing a single alternate access method are encouraged to use `'+'`.

Earlier versions of this standard did not have the –**k** option, which meant that the –**s** option could not be used portably as its block size was implementation-defined, and the units used to specify the number of blocks occupied by files in a directory in an *ls* –**l** listing were fixed as 512-byte units. The –**k** option has been added to provide a way for the –**s** option to be used portably, and for consistency it also changes the aforementioned units from 512-byte to 1 024-byte.

The <*date and time*> field in the –**l** format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of POSIX.1-2017, as the appropriate vehicle is a messaging system; that is, the format should be specified as a ``message''.

FUTURE DIRECTIONS

Allowing –**f** to ignore the –**A**, –**g**, –**l**, –**n**, –**o**, and –**s** options may be removed in a future version.

A future version of this standard may require that if the collating sequence for the current locale does not have a total ordering of all characters, any filenames or pathnames that collate equally are further compared byte-by-byte using the collating sequence for the POSIX locale.

CHANGE HISTORY

First released in Issue 2.

Issue 5

A second FUTURE DIRECTION is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

In the **−F** option, other symbols are allowed for other file types.

Treatment of symbolic links is added, as defined in the IEEE P1003.2b draft standard.

The Open Group Base Resolution bwg2001-010 is applied, adding the `T` and `t` fields as part of the XSI option.

Issue 7

Austin Group Interpretation 1003.1-2001 #101 is applied, clarifying the optional alternate access method flag in the STDOUT section.

Austin Group Interpretation 1003.1-2001 #128 is applied, clarifying the DESCRIPTION and the definition of the **−R** option.

Austin Group Interpretation 1003.1-2001 #129 is applied, clarifying the behavior of *ls* when no operands are specified.

Austin Group Interpretation 1003.1-2001 #198 is applied, clarifying the requirements for the **−H** option.

SD5-XCU-ERN-50 is applied, adding the **−A** option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The **−S** option is added from The Open Group Technical Standard, 2006, Extended API Set Part 1.

The **−f**, **−m**, **−n**, **−p**, **−s**, and **−x** options are moved from the XSI option to the Base.

The description of the **−f**, **−s**, and **−t** options are revised and the **−k** option is added.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0098 [424], XCU/TC1-2008/0099 [424], XCU/TC1-2008/0100 [424], XCU/TC1-2008/0101 [424], XCU/TC1-2008/0102 [424], XCU/TC1-2008/0103 [424], XCU/TC1-2008/0104 [424], XCU/TC1-2008/0105 [423,424], XCU/TC1-2008/0106 [424], XCU/TC1-2008/0107 [424], XCU/TC1-2008/0108 [424], XCU/TC1-2008/0109 [424], XCU/TC1-2008/0110 [424], XCU/TC1-2008/0111 [423], XCU/TC1-2008/0112 [117], XCU/TC1-2008/0113 [117], XCU/TC1-2008/0114 [117], XCU/TC1-2008/0115 [424], and XCU/TC1-2008/0116 [424] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0115 [963] and XCU/TC2-2008/0116 [963] are applied.

97031 **NAME**

97032 m4 ‡'macœ processor

97033 **SYNOPSIS**

97034 `m4 [-s] [-D name[=val]]... [-U name]... file...`

97035 **DESCRIPTION**

97036 The *m4* utility is a macro processor that shall read one or more text files, process them according
97037 to their included macro statements, and write the results to standard output.

97038 **OPTIONS**

97039 The *m4* utility shall conform to XBD Section 12.2 (on page 216), except that the order of the **-D**
97040 and **-U** options shall be significant, and options can be interspersed with operands.

97041 The following options shall be supported:

97042 **-s** Enable line synchronization output for the *c99* preprocessor phase (that is, **#line**
97043 directives).

97044 **-D** *name*[=*val*]
97045 Define *name* to *val* or to null if =*val* is omitted.

97046 **-U** *name* Undefine *name*.

97047 **OPERANDS**

97048 The following operand shall be supported:

97049 *file* A pathname of a text file to be processed. If no *file* is given, or if it is `'-'`, the
97050 standard input shall be read.

97051 **STDIN**

97052 The standard input shall be a text file that is used if no *file* operand is given, or if it is `'-'`.

97053 **INPUT FILES**

97054 The input file named by the *file* operand shall be a text file.

97055 **ENVIRONMENT VARIABLES**

97056 The following environment variables shall affect the execution of *m4*:

97057 *LANG* Provide a default value for the internationalization variables that are unset or null.
97058 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
97059 variables used to determine the values of locale categories.)

97060 *LC_ALL* If set to a non-empty string value, override the values of all the other
97061 internationalization variables.

97062 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
97063 characters (for example, single-byte as opposed to multi-byte characters in
97064 arguments and input files).

97065 *LC_MESSAGES*
97066 Determine the locale that should be used to affect the format and contents of
97067 diagnostic messages written to standard error.

97068 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

97069 **ASYNCHRONOUS EVENTS**

97070 Default.

97071 **STDOUT**

97072 The standard output shall be the same as the input files, after being processed for macro
97073 expansion.

97074 **STDERR**

97075 The standard error shall be used to display strings with the **errprint** macro, macro tracing
97076 enabled by the **traceon** macro, the defined text for macros written by the **dumpdef** macro, or for
97077 diagnostic messages.

97078 **OUTPUT FILES**

97079 None.

97080 **EXTENDED DESCRIPTION**

97081 The *m4* utility shall compare each token from the input against the set of built-in and user-
97082 defined macros. If the token matches the name of a macro, then the token shall be replaced by
97083 the macro's defining text, if any, and rescanned for matching macro names. Once no portion of
97084 the token matches the name of a macro, it shall be written to standard output. Macros may have
97085 arguments, in which case the arguments shall be substituted into the defining text before it is
97086 rescanned.

97087 Macro calls have the form:

97088 *name*(*arg1*, *arg2*, ..., *argn*)

97089 Macro names shall consist of letters, digits, and underscores, where the first character is not a
97090 digit. Tokens not of this form shall not be treated as macros.

97091 The application shall ensure that the <left-parenthesis> immediately follows the name of the
97092 macro. If a token matching the name of a macro is not followed by a <left-parenthesis>, it is
97093 handled as a use of that macro without arguments.

97094 If a macro name is followed by a <left-parenthesis>, its arguments are the <comma>-separated
97095 tokens between the <left-parenthesis> and the matching <right-parenthesis>. Unquoted white-
97096 space characters preceding each argument shall be ignored. All other characters, including
97097 trailing white-space characters, are retained. <comma> characters enclosed between <left-
97098 parenthesis> and <right-parenthesis> characters do not delimit arguments.

97099 Arguments are positionally defined and referenced. The string "`$1`" in the defining text shall be
97100 replaced by the first argument. Systems shall support at least nine arguments; only the first nine
97101 can be referenced, using the strings "`$1`" to "`$9`", inclusive. The string "`$0`" is replaced with
97102 the name of the macro. The string "`$#`" is replaced by the number of arguments as a string. The
97103 string "`$*`" is replaced by a list of all of the arguments, separated by <comma> characters. The
97104 string "`$@`" is replaced by a list of all of the arguments separated by <comma> characters, and
97105 each argument is quoted using the current left and right quoting strings. The string "`${`"
97106 produces unspecified behavior.

97107 If fewer arguments are supplied than are in the macro definition, the omitted arguments are
97108 taken to be null. It is not an error if more arguments are supplied than are in the macro
97109 definition.

97110 No special meaning is given to any characters enclosed between matching left and right quoting
97111 strings, but the quoting strings are themselves discarded. By default, the left quoting string
97112 consists of a grave accent (backquote) and the right quoting string consists of an acute accent
97113 (single-quote); see also the **changequote** macro.

97114 Comments are written but not scanned for matching macro names; by default, the begin-
97115 comment string consists of the <number-sign> character and the end-comment string consists of
97116 a <newline>. See also the **changecom** and **dnl** macros.

The *m4* utility shall make available the following built-in macros. They can be redefined, but once this is done the original meaning is lost. Their values shall be null unless otherwise stated. In the descriptions below, the term *defining text* refers to the value of the macro: the second argument to the **define** macro, among other things. Except for the first argument to the **eval** macro, all numeric arguments to built-in macros shall be interpreted as decimal values. The string values produced as the defining text of the **decr**, **divnum**, **incr**, **index**, **len**, and **sysval** built-in macros shall be in the form of a decimal-constant as defined in the C language.

changecom The **changecom** macro shall set the begin-comment and end-comment strings. With no arguments, the comment mechanism shall be disabled. With a single non-null argument, that argument shall become the begin-comment and the <newline> shall become the end-comment string. With two non-null arguments, the first argument shall become the begin-comment string and the second argument shall become the end-comment string. The behavior is unspecified if either argument is provided but null. Systems shall support comment strings of at least five characters.

changequote The **changequote** macro shall set the begin-quote and end-quote strings. With no arguments, the quote strings shall be set to the default values (that is, `` ` ' ``). The behavior is unspecified if there is a single argument or either argument is null. With two non-null arguments, the first argument shall become the begin-quote string and the second argument shall become the end-quote string. Systems shall support quote strings of at least five characters.

decr The defining text of the **decr** macro shall be its first argument decremented by 1. It shall be an error to specify an argument containing any non-numeric characters. The behavior is unspecified if **decr** is not immediately followed by a <left-parenthesis>.

define The second argument shall become the defining text of the macro whose name is the first argument. It is unspecified whether the **define** macro deletes all prior definitions of the macro named by its first argument or preserves all but the current definition of the macro. The behavior is unspecified if **define** is not immediately followed by a <left-parenthesis>.

defn The defining text of the **defn** macro shall be the quoted definition (using the current quoting strings) of its arguments. The behavior is unspecified if **defn** is not immediately followed by a <left-parenthesis>.

divert The *m4* utility maintains nine temporary buffers, numbered 1 to 9, inclusive. When the last of the input has been processed, any output that has been placed in these buffers shall be written to standard output in buffer-numerical order. The **divert** macro shall divert future output to the buffer specified by its argument. Specifying no argument or an argument of 0 shall resume the normal output process. Output diverted to a stream with a negative number shall be discarded. Behavior is implementation-defined if a stream number larger than 9 is specified. It shall be an error to specify an argument containing any non-numeric characters.

divnum The defining text of the **divnum** macro shall be the number of the current output stream as a string.

dnl The **dnl** macro shall cause *m4* to discard all input characters up to and including the next <newline>.

dumpdef The **dumpdef** macro shall write the defined text to standard error for each of the macros specified as arguments, or, if no arguments are specified, for all macros.

errprint The **errprint** macro shall write its arguments to standard error. The behavior is unspecified if **errprint** is not immediately followed by a <left-parenthesis>.

eval The **eval** macro shall evaluate its first argument as an arithmetic expression, using signed integer arithmetic with at least 32-bit precision. At least the following C-language operators shall be supported, with precedence, associativity, and behavior as described in Section 1.1.2.1 (on page 2331):

```
()
unary +
unary –
~

!
binary *
/
%
binary +
binary –
<<
>>
<
<=
>
>=
==
!=
binary &
^
|
&&
||
```

Systems shall support octal and hexadecimal numbers as in the ISO C standard. The second argument, if specified, shall set the radix for the result; if the argument is blank or unspecified, the default is 10. Behavior is unspecified if the radix falls outside the range 2 to 36, inclusive. The third argument, if specified, sets the minimum number of digits in the result. Behavior is unspecified if the third argument is less than zero. It shall be an error to specify the second or third argument containing any non-numeric characters. The behavior is unspecified if **eval** is not immediately followed by a <left-parenthesis>.

ifdef If the first argument to the **ifdef** macro is defined, the defining text shall be the second argument. Otherwise, the defining text shall be the third argument, if specified, or the null string, if not. The behavior is unspecified if **ifdef** is not immediately followed by a <left-parenthesis>.

ifelse The **ifelse** macro takes three or more arguments. If the first two arguments compare as equal strings (after macro expansion of both arguments), the defining text shall be the third argument. If the first two arguments do not compare as equal strings and there are three arguments, the defining text shall be null. If the first two arguments do not compare as equal strings and there are four or five arguments,

97210 the defining text shall be the fourth argument. If the first two arguments do not
97211 compare as equal strings and there are six or more arguments, the first three
97212 arguments shall be discarded and processing shall restart with the remaining
97213 arguments. The behavior is unspecified if **ifelse** is not immediately followed by a
97214 <left-parenthesis>.

97215 **include** The defining text for the **include** macro shall be the contents of the file named by
97216 the first argument. It shall be an error if the file cannot be read. The behavior is
97217 unspecified if **include** is not immediately followed by a <left-parenthesis>.

97218 **incr** The defining text of the **incr** macro shall be its first argument incremented by 1. It
97219 shall be an error to specify an argument containing any non-numeric characters.
97220 The behavior is unspecified if **incr** is not immediately followed by a <left-
97221 parenthesis>.

97222 **index** The defining text of the **index** macro shall be the first character position (as a
97223 string) in the first argument where a string matching the second argument begins
97224 (zero origin), or −1 if the second argument does not occur. The behavior is
97225 unspecified if **index** is not immediately followed by a <left-parenthesis>.

97226 **len** The defining text of the **len** macro shall be the length (as a string) of the first
97227 argument. The behavior is unspecified if **len** is not immediately followed by a
97228 <left-parenthesis>.

97229 **m4exit** Exit from the *m4* utility. If the first argument is specified, it shall be the exit code. If
97230 no argument is specified, the exit code shall be zero. It shall be an error to specify
97231 an argument containing any non-numeric characters. If the first argument is zero
97232 or no argument is specified, and an error has previously occurred (for example, a
97233 *file* operand that could not be opened), it is unspecified whether the exit status is
97234 zero or non-zero.

97235 **m4wrap** The first argument shall be processed when EOF is reached. If the **m4wrap** macro
97236 is used multiple times, the arguments specified shall be processed in the order in
97237 which the **m4wrap** macros were processed. The behavior is unspecified if **m4wrap**
97238 is not immediately followed by a <left-parenthesis>.

97239 OB **maketemp** The defining text shall be the first argument, with any trailing `'X'` characters
97240 replaced with the current process ID as a string. The behavior is unspecified if
97241 **maketemp** is not immediately followed by a <left-parenthesis>.

97242 **mkstemp** The defining text shall be as if it were the resulting pathname after a successful call
97243 to the *mkstemp*( ) function defined in the System Interfaces volume of POSIX.1-2017
97244 called with the first argument to the macro invocation. If a file is created, that file
97245 shall be closed. If a file could not be created, the *m4* utility shall write a diagnostic
97246 message to standard error and shall continue processing input but its final exit
97247 status shall be non-zero; the defining text of the macro shall be the empty string.
97248 The behavior is unspecified if **mkstemp** is not immediately followed by a <left-
97249 parenthesis>.

97250 **popdef** The **popdef** macro shall delete the current definition of its arguments, replacing
97251 that definition with the previous one. If there is no previous definition, the macro
97252 is undefined. The behavior is unspecified if **popdef** is not immediately followed by
97253 a <left-parenthesis>.

97254 **pushdef** The **pushdef** macro shall be equivalent to the **define** macro with the exception that
97255 it shall preserve any current definition for future retrieval using the **popdef** macro.
97256 The behavior is unspecified if **pushdef** is not immediately followed by a <left-

97257 parenthesis>.

97258 **shift** The defining text for the **shift** macro shall be a comma-separated list of its
97259 arguments except the first one. Each argument shall be quoted using the current
97260 quoting strings. The behavior is unspecified if **shift** is not immediately followed
97261 by a <left-parenthesis>.

97262 **sinclude** The **sinclude** macro shall be equivalent to the **include** macro, except that it shall
97263 not be an error if the file is inaccessible. The behavior is unspecified if **sinclude** is
97264 not immediately followed by a <left-parenthesis>.

97265 **substr** The defining text for the **substr** macro shall be the substring of the first argument
97266 beginning at the zero-offset character position specified by the second argument.
97267 The third argument, if specified, shall be the number of characters to select; if not
97268 specified, the characters from the starting point to the end of the first argument
97269 shall become the defining text. It shall not be an error to specify a starting point
97270 beyond the end of the first argument and the defining text shall be null. It shall be
97271 an error to specify an argument containing any non-numeric characters. The
97272 behavior is unspecified if **substr** is not immediately followed by a <left-
97273 parenthesis>.

97274 **syscmd** The **syscmd** macro shall interpret its first argument as a shell command line. The
97275 defining text shall be the string result of that command. The string result shall not
97276 be rescanned for macros while setting the defining text. No output redirection shall
97277 be performed by the *m4* utility. The exit status value from the command can be
97278 retrieved using the **sysval** macro. The behavior is unspecified if **syscmd** is not
97279 immediately followed by a <left-parenthesis>.

97280 **sysval** The defining text of the **sysval** macro shall be the exit value of the utility last
97281 invoked by the **syscmd** macro (as a string).

97282 **traceon** The **traceon** macro shall enable tracing for the macros specified as arguments, or, if
97283 no arguments are specified, for all macros. The trace output shall be written to
97284 standard error in an unspecified format.

97285 **traceoff** The **traceoff** macro shall disable tracing for the macros specified as arguments, or,
97286 if no arguments are specified, for all macros.

97287 **translit** The defining text of the **translit** macro shall be the first argument with every
97288 character that occurs in the second argument replaced with the corresponding
97289 character from the third argument. If no replacement character is specified for
97290 some source character because the second argument is longer than the third
97291 argument, that character shall be deleted from the first argument in **translit**'s
97292 defining text. The behavior is unspecified if the `'-'` character appears within the
97293 second or third argument anywhere besides the first or last character. The behavior
97294 is unspecified if the same character appears more than once in the second
97295 argument. The behavior is unspecified if **translit** is not immediately followed by a
97296 <left-parenthesis>.

97297 **undefine** The **undefine** macro shall delete all definitions (including those preserved using
97298 the **pushdef** macro) of the macros named by its arguments. The behavior is
97299 unspecified if **undefine** is not immediately followed by a <left-parenthesis>.

97300 **undivert** The **undivert** macro shall cause immediate output of any text in temporary buffers
97301 named as arguments, or all temporary buffers if no arguments are specified.
97302 Buffers can be undiverted into other temporary buffers. Undiverting shall discard
97303 the contents of the temporary buffer. The behavior is unspecified if an argument

97304 contains any non-numeric characters.

97305 **EXIT STATUS**

97306 The following exit values shall be returned:

97307 0 Successful completion.

97308 >0 An error occurred

97309 If the **m4exit** macro is used, the exit value can be specified by the input file.

97310 **CONSEQUENCES OF ERRORS**

97311 Default.

97312 **APPLICATION USAGE**

97313 The **defn** macro is useful for renaming macros, especially built-ins.

97314 Since **eval** defers to the ISO C standard, some operations have undefined behavior. In some
97315 implementations, division or remainder by zero cause a fatal signal, even if the division occurs
97316 on the short-circuited branch of "`&&`" or "`||`". Any operation that overflows in signed
97317 arithmetic produces undefined behavior. Likewise, using the **shift** operators with a shift amount
97318 that is not positive and smaller than the precision is undefined, as is shifting a negative number
97319 to the right. Historically, not all implementations obeyed C-language precedence rules: '`~`' and
97320 '`!`' were lower than '`==`'; '`==`' and '`!=`' were not lower than '`<`'; and '`|`' was not lower
97321 than '`^`'; the liberal use of "`()`" can force the desired precedence even with these non-
97322 compliant implementations. Furthermore, some traditional implementations treated '`^`' as an
97323 exponentiation operator, although most implementations now use "`**`" as an extension for this
97324 purpose.

97325 When a macro has been multiply defined via the **pushdef** macro, it is unspecified whether the
97326 **define** macro will alter only the most recent definition (as though by **popdef** and **pushdef**), or
97327 replace the entire stack of definitions with a single definition (as though by **undefine** and
97328 **pushdef**). An application desiring particular behavior for the **define** macro in this case can
97329 redefine it accordingly.

97330 Applications should use the **mkstemp** macro instead of the obsolescent **maketemp** macro for
97331 creating temporary files.

97332 **EXAMPLES**

97333 If the file **m4src** contains the lines:

```
97334 The value of `VER' is "VER".
97335 ifdef(`VER', ``VER'' is defined to be VER., VER is not defined.)
97336 ifelse(VER, 1, ``VER'' is `VER'.)
97337 ifelse(VER, 2, ``VER'' is `VER'., ``VER'' is not 2.)
97338 end
```

97339 then the command

```
97340 m4 m4src
```

97341 or the command:

```
97342 m4 –U VER m4src
```

97343 produces the output:

```
97344 The value of VER is "VER".
97345 VER is not defined.
97346 VER is not 2.
```

```
end
```

The command:

```
m4 -D VER m4src
```

produces the output:

```
The value of VER is "".
VER is defined to be .
VER is not 2.
end
```

The command:

```
m4 -D VER=1 m4src
```

produces the output:

```
The value of VER is "1".
VER is defined to be 1.
VER is 1.
VER is not 2.
end
```

The command:

```
m4 -D VER=2 m4src
```

produces the output:

```
The value of VER is "2".
VER is defined to be 2.
VER is 2.
end
```

RATIONALE

Historic System V-based behavior treated `"${"` in a macro definition as two literal characters. However, this sequence is left unspecified so that implementations may offer extensions such as `"${11}"` meaning the eleventh positional parameter. Macros can still be defined with appropriate uses of nested quoting to result in a literal `"${"` in the output after rescanning removes the nested quotes.

In the **translit** built-in, historic System V-based behavior treated `'-'` as a literal; GNU behavior treats it as a range. This version of the standard allows either behavior.

FUTURE DIRECTIONS

None.

SEE ALSO

c99

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The phrase ``the defined text for macros written by the **dumpdef** macro'' is added to the description of STDERR, and the description of **dumpdef** is updated to indicate that output is written to standard error. The description of **eval** is updated to indicate that the list of excluded C operators excludes unary `'&'` and `'.'`. In the description of **ifdef**, the phrase ``and it is not defined to be zero'' is deleted.

Issue 6

In the EXTENDED DESCRIPTION, the **eval** text is updated to include a `'&'` character in the excepted list.

The EXTENDED DESCRIPTION of **divert** is updated to clarify that there are only nine diversion buffers.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The Open Group Base Resolution bwg2000-006 is applied.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/31 is applied, replacing the EXAMPLES section.

Issue 7

Austin Group Interpretation 1003.1-2001 #117 is applied, marking the **maketemp** macro obsolescent and adding a new **mkstemp** macro.

Austin Group Interpretation 1003.1-2001 #207 is applied, clarifying the handling of white-space characters that precede or trail any macro arguments.

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply (options can be interspersed with operands).

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-99 is applied, clarifying the definition of the **divert** macro in the EXTENDED DESCRIPTION.

SD5-XCU-ERN-100 is applied, clarifying the definition of the **syscmd** macro in the EXTENDED DESCRIPTION.

SD5-XCU-ERN-101 is applied, clarifying the definition of the **undivert** macro in the EXTENDED DESCRIPTION.

SD5-XCU-ERN-111 is applied to the EXTENDED DESCRIPTION, clarifying that the string `"${"` produces unspecified behavior.

SD5-XCU-ERN-112 is applied, updating the **changequote** macro.

SD5-XCU-ERN-118 is applied, clarifying the definition of the **define** macro in the EXTENDED DESCRIPTION and APPLICATION USAGE sections.

SD5-XCU-ERN-119 is applied, clarifying the definition of the **translit** macro in the EXTENDED DESCRIPTION and RATIONALE sections.

SD5-XCU-ERN-130, SD5-XCU-ERN-131, and SD5-XCU-ERN-137 are applied.

The *m4* utility is moved from the XSI option to the Base.

97423 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0117 [241], XCU/TC1-2008/0118
97424 [242,431], XCU/TC1-2008/0119 [242,431], and XCU/TC1-2008/0120 [325,430] are applied.

97425 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0117 [964], XCU/TC2-2008/0118 [970],
97426 and XCU/TC2-2008/0119 [964] are applied.

NAME

mailx — process messages

SYNOPSIS

Send Mode

```
mailx [−s subject] address...
```

Receive Mode

UP

```
mailx −e
mailx [−HiNn] [−F] [−u user]
mailx −f [−HiNn] [−F] [file]
```

DESCRIPTION

The *mailx* utility provides a message sending and receiving facility. It has two major modes, selected by the options used: Send Mode and Receive Mode.

On systems that do not support the User Portability Utilities option, an application using *mailx* shall have the ability to send messages in an unspecified manner (Send Mode). Unless the first character of one or more lines is <tilde> (`'~'`), all characters in the input message shall appear in the delivered message, but additional characters may be inserted in the message before it is retrieved.

UP On systems supporting the User Portability Utilities option, mail-receiving capabilities and other interactive features, Receive Mode, described below, also shall be enabled.

Send Mode

Send Mode can be used by applications or users to send messages from the text in standard input.

UP

Receive Mode

Receive Mode is more oriented towards interactive users. Mail can be read and sent in this interactive mode.

When reading mail, *mailx* provides commands to facilitate saving, deleting, and responding to messages. When sending mail, *mailx* allows editing, reviewing, and other modification of the message as it is entered.

Incoming mail shall be stored in one or more unspecified locations for each user, collectively called the system *mailbox* for that user. When *mailx* is invoked in Receive Mode, the system mailbox shall be the default place to find new mail. As messages are read, they shall be marked to be moved to a secondary file for storage, unless specific action is taken. This secondary file is called the **mbox** and is normally located in the directory referred to by the *HOME* environment variable (see *MBOX* in the ENVIRONMENT VARIABLES section for a description of this file). Messages shall remain in this file until explicitly removed. When the **−f** option is used to read mail messages from secondary files, messages shall be retained in those files unless specifically removed. All three of these locations—system mailbox, **mbox**, and secondary file ‡are referred to in this section as simply ``mailboxes'', unless more specific identification is required.

OPTIONS

The *mailx* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported. (Only the **−s** *subject* option shall be required on all systems. The other options are required only on systems supporting the User Portability Utilities option.)

UP **−e** Test for the presence of mail in the system mailbox. The *mailx* utility shall write nothing and exit with a successful return code if there is mail to read.

UP **−f** Read messages from the file named by the *file* operand instead of the system mailbox. (See also **folder**.) If no *file* operand is specified, read messages from **mbox** instead of the system mailbox.

UP **−F** Record the message in a file named after the first recipient. The name is the login-name portion of the address found first on the **To:** line in the mail header. Overrides the **record** variable, if set (see Internal Variables in mailx, on page 2950).

UP **−H** Write a header summary only.

UP **−i** Ignore interrupts. (See also **ignore**.)

UP **−n** Do not initialize from the system default start-up file. See the EXTENDED DESCRIPTION section.

UP **−N** Do not write an initial header summary.

−s *subject* Set the **Subject** header field to *subject*. All characters in the *subject* string shall appear in the delivered message. The results are unspecified if *subject* is longer than {LINE_MAX} − 10 bytes or contains a <newline>.

UP **−u** *user* Read the system mailbox of the login name *user*. This shall only be successful if the invoking user has appropriate privileges to read the system mailbox of that user.

OPERANDS

The following operands shall be supported:

address Addressee of message. When **−n** is specified and no user start-up files are accessed (see the EXTENDED DESCRIPTION section), the user or application shall ensure this is an address to pass to the mail delivery system. Any system or user start-up files may enable aliases (see **alias** under Commands in mailx, on page 2953) that may modify the form of *address* before it is passed to the mail delivery system.

UP *file* A pathname of a file to be read instead of the system mailbox when **−f** is specified. The meaning of the *file* option-argument shall be affected by the contents of the **folder** internal variable; see Internal Variables in mailx (on page 2950).

STDIN

When *mailx* is invoked in Send Mode (the first synopsis line), standard input shall be the
UP message to be delivered to the specified addresses. When in Receive Mode, user commands shall be accepted from *stdin*. If the User Portability Utilities option is not supported, standard input lines beginning with a <tilde> (`'~'`) character produce unspecified results.

UP If the User Portability Utilities option is supported, then in both Send and Receive Modes, standard input lines beginning with the escape character (usually <tilde> (`'~'`)) shall affect processing as described in Command Escapes in mailx (on page 2962).

INPUT FILES

When *mailx* is used as described by this volume of POSIX.1-2017, the *file* option-argument (see the **−f** option) and the **mbox** shall be text files containing mail messages, formatted as described in the OUTPUT FILES section. The nature of the system mailbox is unspecified; it need not be a file.

ENVIRONMENT VARIABLES

UP Some of the functionality described in this section shall be provided on implementations that support the User Portability Utilities option as described in the text, and is not further shaded for this option.

The following environment variables shall affect the execution of *mailx*:

DEAD Determine the pathname of the file in which to save partial messages in case of interrupts or delivery errors. The default shall be **dead.letter** in the directory named by the *HOME* variable. The behavior of *mailx* in saving partial messages is unspecified if the User Portability Utilities option is not supported and *DEAD* is not defined with the value **/dev/null**.

EDITOR Determine the name of a utility to invoke when the **edit** (see Commands in mailx, on page 2953) or **~e** (see Command Escapes in mailx, on page 2962) command is used. The default editor is unspecified. XSI On XSI-conformant systems it is *ed*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

HOME Determine the pathname of the user's home directory.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the handling of case-insensitive address and header-field comparisons.

LC_TIME This variable may determine the format and contents of the date and time strings written by *mailx*. This volume of POSIX.1-2017 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LISTER Determine a string representing the command for writing the contents of the **folder** directory to standard output when the **folders** command is given (see **folders** in Commands in mailx, on page 2953). Any string acceptable as a *command_string* operand to the *sh* **−c** command shall be valid. If this variable is null or not set, the output command shall be *ls*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

MAILRC Determine the pathname of the user start-up file. The default shall be **.mailrc** in the directory referred to by the *HOME* environment variable. The behavior of *mailx* is unspecified if the User Portability Utilities option is not supported and *MAILRC* is

not defined with the value **/dev/null**.

MBOX Determine a pathname of the file to save messages from the system mailbox that have been read. The **exit** command shall override this function, as shall saving the message explicitly in another file. The default shall be **mbox** in the directory named by the *HOME* variable. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PAGER Determine a string representing an output filtering or pagination command for writing the output to the terminal. Any string acceptable as a *command_string* operand to the *sh* **−c** command shall be valid. When standard output is a terminal device, the message output shall be piped through the command if the *mailx* internal variable **crt** is set to a value less the number of lines in the message; see Internal Variables in mailx (on page 2950). If the *PAGER* variable is null or not set, the paginator shall be either *more* or another paginator utility documented in the system documentation. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

SHELL Determine the name of a preferred command interpreter. The default shall be *sh*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

TERM If the internal variable **screen** is not specified, determine the name of the terminal type to indicate in an unspecified manner the number of lines in a screenful of headers. If *TERM* is not set or is set to null, an unspecified default terminal type shall be used and the value of a screenful is unspecified. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

TZ This variable may determine the timezone used to calculate date and time strings written by *mailx*. If *TZ* is unset or null, an unspecified default timezone shall be used.

VISUAL Determine a pathname of a utility to invoke when the **visual** command (see Commands in mailx, on page 2953) or **~v** command-escape (see Command Escapes in mailx, on page 2962) is used. If this variable is null or not set, the full-screen editor shall be *vi*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

ASYNCHRONOUS EVENTS

When *mailx* is in Send Mode and standard input is not a terminal, it shall take the standard action for all signals.

UP In Receive Mode, or in Send Mode when standard input is a terminal, if a SIGINT signal is received:

UP 1. If in command mode, the current command, if there is one, shall be aborted, and a command-mode prompt shall be written.

2. If in input mode:

UP a. If **ignore** is set, *mailx* shall write `"@\n"`, discard the current input line, and continue processing, bypassing the message-abort mechanism described in item 2b.

97596 UP b. If the interrupt was received while sending mail, either when in Receive Mode or
97597 in Send Mode, a message shall be written, and another subsequent interrupt, with
97598 no other intervening characters typed, shall be required to abort the mail message.
97599 UP If in Receive Mode and another interrupt is received, a command-mode prompt
97600 shall be written. If in Send Mode and another interrupt is received, *mailx* shall
97601 terminate with a non-zero status.

97602 In both cases listed in item b, if the message is not empty:

97603 UP i. If **save** is enabled and the file named by *DEAD* can be created, the message
97604 shall be written to the file named by *DEAD*. If the file exists, the message
97605 shall be written to replace the contents of the file.

97606 UP ii. If **save** is not enabled, or the file named by *DEAD* cannot be created, the
97607 message shall not be saved.

97608 The *mailx* utility shall take the standard action for all other signals.

97609 **STDOUT**

97610 In command and input modes, all output, including prompts and messages, shall be written to
97611 standard output.

97612 **STDERR**

97613 The standard error shall be used only for diagnostic messages.

97614 **OUTPUT FILES**

97615 Various *mailx* commands and command escapes can create or add to files, including the **mbox**,
97616 the dead-letter file, and secondary mailboxes. When *mailx* is used as described in this volume of
97617 POSIX.1-2017, these files shall be text files, formatted as follows:

97618 `line beginning with` **`From<space>`**
97619 **`[`**`one or more` *`header-lines`*; see Commands in mailx (on page 2953)**`]`**
97620 *`empty line`*
97621 **`[`**`zero or more` *`body lines`*
97622 *`empty line]`*
97623 **`[`**`line beginning with` **`From<space>...]`**

97624 where each message begins with the **From <space>** line shown, preceded by the beginning of
97625 the file or an empty line. (The **From <space>** line is considered to be part of the message header,
97626 but not one of the header-lines referred to in Commands in mailx (on page 2953); thus, it shall
97627 not be affected by the **discard**, **ignore**, or **retain** commands.) The formats of the remainder of the
97628 **From <space>** line and any additional header lines are unspecified, except that none shall be
97629 empty. The format of a message body line is also unspecified, except that no line following an
97630 empty line shall start with **From <space>**; *mailx* shall modify any such user-entered message
97631 body lines (following an empty line and beginning with **From <space>**) by adding one or more
97632 characters to precede the `'F'`; it may add these characters to **From <space>** lines that are not
97633 preceded by an empty line.

97634 When a message from the system mailbox or entered by the user is not a text file, it is
97635 implementation-defined how such a message is stored in files written by *mailx*.

97636 **EXTENDED DESCRIPTION**

97637 UP The functionality in the entire EXTENDED DESCRIPTION section shall be provided on
97638 implementations supporting the User Portability Utilities option. The functionality described in
97639 this section shall be provided on implementations that support the User Portability Utilities
97640 option (and the rest of this section is not further shaded for this option).

97641 The *mailx* utility need not support for all character encodings in all circumstances. For example,
97642 inter-system mail may be restricted to 7-bit data by the underlying network, 8-bit data need not
97643 be portable to non-internationalized systems, and so on. Under these circumstances, it is
97644 recommended that only characters defined in the ISO/IEC 646:1991 standard International
97645 Reference Version (equivalent to ASCII) 7-bit range of characters be used.

97646 When *mailx* is invoked using one of the Receive Mode synopsis forms, it shall write a page of
97647 header-summary lines (if **−N** was not specified and there are messages, see below), followed by
97648 a prompt indicating that *mailx* can accept regular commands (see Commands in mailx, on page
97649 2953); this is termed *command mode*. The page of header-summary lines shall contain the first
97650 new message if there are new messages, or the first unread message if there are unread
97651 messages, or the first message. When *mailx* is invoked using the Send Mode synopsis and
97652 standard input is a terminal, if no subject is specified on the command line and the **asksub**
97653 variable is set, a prompt for the subject shall be written. At this point, *mailx* shall be in input
97654 mode. This input mode shall also be entered when using one of the Receive Mode synopsis
97655 forms and a reply or new message is composed using the **reply**, **Reply**, **followup**, **Followup**, or
97656 **mail** commands and standard input is a terminal. When the message is typed and the end of the
97657 message is encountered, the message shall be passed to the mail delivery software. Commands
97658 can be entered by beginning a line with the escape character (by default, <tilde> (`'~'`)) followed
97659 by a single command letter and optional arguments. See Commands in mailx (on page 2953) for
97660 a summary of these commands. It is unspecified what effect these commands will have if
97661 standard input is not a terminal when a message is entered using either the Send Mode
97662 synopsis, or the Read Mode commands **reply**, **Reply**, **followup**, **Followup**, or **mail**.

97663 **Note:** For notational convenience, this section uses the default escape character, <tilde>, in all
97664 references and examples.

97665 At any time, the behavior of *mailx* shall be governed by a set of environmental and internal
97666 variables. These are flags and valued parameters that can be set and cleared via the *mailx* **set**
97667 and **unset** commands.

97668 Regular commands are of the form:

97669 **[***command***] [***msglist***] [***argument ...***]**

97670 If no *command* is specified in command mode, **next** shall be assumed. In input mode, commands
97671 shall be recognized by the escape character, and lines not treated as commands shall be taken as
97672 input for the message.

97673 In command mode, each message shall be assigned a sequential number, starting with 1.

97674 All messages have a state that shall affect how they are displayed in the header summary and
97675 how they are retained or deleted upon termination of *mailx*. There is at any time the notion of a
97676 *current* message, which shall be marked by a `'>'` at the beginning of a line in the header
97677 summary. When *mailx* is invoked using one of the Receive Mode synopsis forms, the current
97678 message shall be the first new message, if there is a new message, or the first unread message if
97679 there is an unread message, or the first message if there are any messages, or unspecified if there
97680 are no messages in the mailbox. Each command that takes an optional list of messages (*msglist*)
97681 or an optional single message (*message*) on which to operate shall leave the current message set
97682 to the highest-numbered message of the messages specified, unless the command deletes
97683 messages, in which case the current message shall be set to the first undeleted message (that is, a
97684 message not in the deleted state) after the highest-numbered message deleted by the command,
97685 if one exists, or the first undeleted message before the highest-numbered message deleted by the
97686 command, if one exists, or to an unspecified value if there are no remaining undeleted messages.
97687 All messages shall be in one of the following states:

97688 97689 97690 *new* The message is present in the system mailbox and has not been viewed by the user or moved to any other state. Messages in state *new* when *mailx* quits shall be retained in the system mailbox.

97691 97692 97693 *unread* The message has been present in the system mailbox for more than one invocation of *mailx* and has not been viewed by the user or moved to any other state. Messages in state *unread* when *mailx* quits shall be retained in the system mailbox.

97694 97695 97696 97697 97698 97699 97700 97701 *read* The message has been processed by one of the following commands: **~f**, **~m**, **~F**, **~M**, **copy**, **mbox**, **next**, **pipe**, **print**, **Print**, **top**, **type**, **Type**, **undelete**. The **delete**, **dp**, and **dt** commands may also cause the next message to be marked as *read*, depending on the value of the **autoprint** variable. Messages that are in the system mailbox and in state *read* when *mailx* quits shall be saved in the **mbox**, unless the internal variable **hold** was set. Messages that are in the **mbox** or in a secondary mailbox and in state *read* when *mailx* quits shall be retained in their current location.

97702 97703 97704 97705 97706 97707 97708 97709 *deleted* The message has been processed by one of the following commands: **delete**, **dp**, **dt**. Messages in state *deleted* when *mailx* quits shall be deleted. Deleted messages shall be ignored until *mailx* quits or changes mailboxes or they are specified to the undelete command; for example, the message specification */string* shall only search the subject lines of messages that have not yet been deleted, unless the command operating on the list of messages is **undelete**. No deleted message or deleted message header shall be displayed by any *mailx* command other than **undelete**.

97710 97711 *preserved* The message has been processed by a **preserve** command. When *mailx* quits, the message shall be retained in its current location.

97712 97713 97714 97715 97716 97717 *saved* The message has been processed by one of the following commands: **save** or **write**. If the current mailbox is the system mailbox, and the internal variable **keepsave** is set, messages in the state saved shall be saved to the file designated by the *MBOX* variable (see the ENVIRONMENT VARIABLES section). If the current mailbox is the system mailbox, messages in the state *saved* shall be deleted from the current mailbox, when the **quit** or **file** command is used to exit the current mailbox.

97718 The header-summary line for each message shall indicate the state of the message.

97719 97720 97721 Many commands take an optional list of messages (*msglist*) on which to operate, which defaults to the current message. A *msglist* is a list of message specifications separated by <blank> characters, which can include:

97722 `n` Message number *n*.

97723 `+` The next undeleted message, or the next deleted message for the **undelete** command.

97724 97725 – The next previous undeleted message, or the next previous deleted message for the **undelete** command.

97726 `.` The current message.

97727 `^` The first undeleted message, or the first deleted message for the **undelete** command.

97728 `$` The last message.

97729 `*` All messages.

97730 `n-m` An inclusive range of message numbers.

97731 *address* All messages from *address*; any address as shown in a header summary shall be
97732 matchable in this form.

97733 */string* All messages with *string* in the subject line (case ignored).

97734 `:c` All messages of type *c*, where *c* shall be one of:

97735 `d` Deleted messages.

97736 `n` New messages.

97737 `o` Old messages (any not in state *read* or *new*).

97738 `r` Read messages.

97739 `u` Unread messages.

97740 Other commands take an optional message (*message*) on which to operate, which defaults to the
97741 current message. All of the forms allowed for *msglist* are also allowed for *message*, but if more
97742 than one message is specified, only the first shall be operated on.

97743 Other arguments are usually arbitrary strings whose usage depends on the command involved.

97744 **Start-Up in mailx**

97745 At start-up time, *mailx* shall take the following steps in sequence:

97746 1. Establish all variables at their stated default values.

97747 2. Process command line options, overriding corresponding default values.

97748 3. Import any of the *DEAD*, *EDITOR*, *MBOX*, *LISTER*, *PAGER*, *SHELL*, or *VISUAL* variables
97749 that are present in the environment, overriding the corresponding default values.

97750 4. Read *mailx* commands from an unspecified system start-up file, unless the **−n** option is
97751 given, to initialize any internal *mailx* variables and aliases.

97752 5. Process the user start-up file of *mailx* commands named in the user *MAILRC* variable.

97753 Most regular *mailx* commands are valid inside start-up files, the most common use being to set
97754 up initial display options and alias lists. The following commands shall be invalid in a start-up
97755 file: **!**, **edit**, **hold**, **mail**, **preserve**, **reply**, **Reply**, **shell**, **visual**, **Copy**, **followup**, and **Followup**.
97756 Any errors in a start-up file shall either cause *mailx* to terminate with a diagnostic message and a
97757 non-zero status or to continue after writing a diagnostic message, ignoring the remainder of the
97758 lines in the file.

97759 A blank line in a start-up file shall be ignored.

97760 **Internal Variables in mailx**

97761 The following variables are internal *mailx* variables. Each internal variable can be set via the
97762 *mailx* **set** command at any time. The **unset** and **set no** *name* commands can be used to erase
97763 variables.

97764 In the following list, variables shown as:

97765 `variable`

97766 represent Boolean values. Variables shown as:

97767 `variable=`*`value`*

shall be assigned string or numeric values. For string values, the rules in Commands in mailx (on page 2953) concerning filenames and quoting shall also apply.

The defaults specified here may be changed by the unspecified system start-up file unless the user specifies the –**n** option.

allnet All network names whose login name components match shall be treated as identical. This shall cause the *msglist* message specifications to behave similarly. The default shall be **noallnet**. See also the **alternates** command and the **metoo** variable.

append Append messages to the end of the **mbox** file upon termination instead of placing them at the beginning. The default shall be **noappend**. This variable shall not affect the **save** command when saving to **mbox**.

ask, **asksub** Prompt for a subject line on outgoing mail if one is not specified on the command line with the –**s** option. The **ask** and **asksub** forms are synonyms; the system shall refer to **asksub** and **noasksub** in its messages, but shall accept **ask** and **noask** as user input to mean **asksub** and **noasksub**. It shall not be possible to set both **ask** and **noasksub**, or **noask** and **asksub**. The default shall be **asksub**, but no prompting shall be done if standard input is not a terminal.

askbcc Prompt for the blind copy list. The default shall be **noaskbcc**.

askcc Prompt for the copy list. The default shall be **noaskcc**.

autoprint Enable automatic writing of messages after **delete** and **undelete** commands. The default shall be **noautoprint**.

bang Enable the special-case treatment of <exclamation-mark> characters (`'!'`) in escape command lines; see the **escape** command and Command Escapes in mailx (on page 2962). The default shall be **nobang**, disabling the expansion of `'!'` in the *command* argument to the **~!** command and the **~<!***command* escape.

cmd=*command*
Set the default command to be invoked by the **pipe** command. The default shall be **nocmd**.

crt=*number* Pipe messages having more than *number* lines through the command specified by the value of the *PAGER* variable. The default shall be **nocrt**. If it is set to null, the value used is implementation-defined.

XSI **debug** Enable verbose diagnostics for debugging. Messages are not delivered. The default shall be **nodebug**.

dot When **dot** is set, a <period> on a line by itself during message input from a terminal shall also signify end-of-file (in addition to normal end-of-file). The default shall be **nodot**. If **ignoreeof** is set (see below), a setting of **nodot** shall be ignored and the <period> is the only method to terminate input mode.

escape=*c* Set the command escape character to be the character `'c'`. By default, the command escape character shall be <tilde>. If **escape** is unset, <tilde> shall be used; if it is set to null, command escaping shall be disabled.

flipr Reverse the meanings of the **R** and **r** commands. The default shall be **noflipr**.

folder=*directory*
The default directory for saving mail files. User-specified filenames beginning with a <plus-sign> (`'+'`) shall be expanded by preceding the filename with this

97812 directory name to obtain the real pathname. If *directory* does not start with a
97813 <slash> (`'/'`), the contents of *HOME* shall be prefixed to it. The default shall be
97814 **nofolder**. If **folder** is unset or set to null, user-specified filenames beginning with
97815 `'+'` shall refer to files in the current directory that begin with the literal `'+'`
97816 character. See also **outfolder** below. The **folder** value need not affect the processing
97817 of the files named in *MBOX* and *DEAD*.

97818 **header** Enable writing of the header summary when entering *mailx* in Receive Mode. The
97819 default shall be **header**.

97820 **hold** Preserve all messages that are read in the system mailbox instead of putting them
97821 in the **mbox** save file. The default shall be **nohold**.

97822 **ignore** Ignore interrupts while entering messages. The default shall be **noignore**.

97823 **ignoreeof** Ignore normal end-of-file during message input. Input can be terminated only by
97824 entering a <period> (`'.'`) on a line by itself or by the **~.** command escape. The
97825 default shall be **noignoreeof**. See also **dot** above.

97826 **indentprefix**=*string*
97827 A string that shall be added as a prefix to each line that is inserted into the message
97828 by the **~m** command escape. This variable shall default to one <tab>.

97829 **keep** When a system mailbox, secondary mailbox, or **mbox** is empty, truncate it to zero
97830 length instead of removing it. The default shall be **nokeep**.

97831 **keepsave** Keep the messages that have been saved from the system mailbox into other files
97832 in the file designated by the variable *MBOX*, instead of deleting them. The default
97833 shall be **nokeepsave**.

97834 **metoo** Suppress the deletion of the login name of the user from the recipient list when
97835 replying to a message or sending to a group. The default shall be **nometoo**.

97836 XSI **onehop** When responding to a message that was originally sent to several recipients, the
97837 other recipient addresses are normally forced to be relative to the originating
97838 author's machine for the response. This flag disables alteration of the recipients'
97839 addresses, improving efficiency in a network where all machines can send directly
97840 to all other machines (that is, one hop away). The default shall be **noonehop**.

97841 **outfolder** Cause the files used to record outgoing messages to be located in the directory
97842 specified by the **folder** variable unless the pathname is absolute. The default shall
97843 be **nooutfolder**. See the **record** variable.

97844 **page** Insert a <form-feed> after each message sent through the pipe created by the **pipe**
97845 command. The default shall be **nopage**.

97846 **prompt**=*string*
97847 Set the command-mode prompt to *string*. If *string* is null or if **noprompt** is set, no
97848 prompting shall occur. The default shall be to prompt with the string `"? "`.

97849 **quiet** Refrain from writing the opening message and version when entering *mailx*. The
97850 default shall be **noquiet**.

97851 **record**=*file* Record all outgoing mail in the file with the pathname *file*. The default shall be
97852 **norecord**. See also **outfolder** above.

97853 **save** Enable saving of messages in the dead-letter file on interrupt or delivery error. See
97854 the variable *DEAD* for the location of the dead-letter file. The default shall be **save**.

97855 **screen**=*number*
97856 Set the number of lines in a screenful of headers for the **headers** and **z** commands.
97857 If **screen** is not specified, a value based on the terminal type identified by the
97858 *TERM* environment variable, the window size, the baud rate, or some combination
97859 of these shall be used.

97860 **sendwait** Wait for the background mailer to finish before returning. The default shall be
97861 **nosendwait**.

97862 **showto** When the sender of the message was the user who is invoking *mailx*, write the
97863 information from the **To:** line instead of the **From:** line in the header summary. The
97864 default shall be **noshowto**.

97865 **sign**=*string* Set the variable inserted into the text of a message when the **~a** command escape is
97866 given. The default shall be **nosign**. The character sequences `'\t'` and `'\n'` shall
97867 be recognized in the variable as <tab> and <newline> characters, respectively. (See
97868 also **~i** in Command Escapes in mailx (on page 2962).)

97869 **Sign**=*string* Set the variable inserted into the text of a message when the **~A** command escape is
97870 given. The default shall be **noSign**. The character sequences `'\t'` and `'\n'` shall
97871 be recognized in the variable as <tab> and <newline> characters, respectively.

97872 **toplines**=*number*
97873 Set the number of lines of the message to write with the **top** command. The default
97874 shall be 5.

97875 **Commands in mailx**

97876 The following *mailx* commands shall be provided. In the following list, header refers to lines
97877 from the message header, as shown in the OUTPUT FILES section. Header-line refers to lines
97878 within the header that begin with one or more non-white-space characters, immediately
97879 followed by a <colon> and white space and continuing until the next line beginning with a non-
97880 white-space character or an empty line. Header-field refers to the portion of a header line prior
97881 to the first <colon> in that line.

97882 For each of the commands listed below, the command can be entered as the abbreviation (those
97883 characters in the Synopsis command word preceding the `'['`), the full command (all characters
97884 shown for the command word, omitting the `'['` and `']'`), or any truncation of the full
97885 command down to the abbreviation. For example, the **exit** command (shown as **ex[it]** in the
97886 Synopsis) can be entered as **ex**, **exi**, or **exit**.

97887 The arguments to commands can be quoted, using the following methods:

97888 An argument can be enclosed between paired double-quotes (`""`) or single-quotes (`''`);
97889 any white space, shell word expansion, or <backslash> characters within the quotes shall
97890 be treated literally as part of the argument. A double-quote shall be treated literally within
97891 single-quotes and *vice versa*. These special properties of the <quotation-mark> characters
97892 shall occur only when they are paired at the beginning and end of the argument.

97893 A <backslash> outside of the enclosing quotes shall be discarded and the following
97894 character treated literally as part of the argument.

97895 An unquoted <backslash> at the end of a command line shall be discarded and the next
97896 line shall continue the command.

Filenames, where expected, shall be subjected to the following transformations, in sequence:

If the filename begins with an unquoted <plus-sign>, and the **folder** variable is defined (see the **folder** variable), the <plus-sign> shall be replaced by the value of the **folder** variable followed by a <slash>. If the **folder** variable is unset or is set to null, the filename shall be unchanged.

Shell word expansions shall be applied to the filename (see Section 2.6, on page 2353). If more than a single pathname results from this expansion and the command is expecting one file, the effects are unspecified.

Declare Aliases

Synopsis: `a[lias] [`*`alias`* `[`*`address...`*`]]`
`g[roup] [`*`alias`* `[`*`address...`*`]]`

Add the given addresses to the alias specified by *alias*. The names shall be substituted when *alias* is used as a recipient address specified by the user in an outgoing message (that is, other recipients addressed indirectly through the **reply** command shall not be substituted in this manner). Mail address alias substitution shall apply only when the alias string is used as a full address; for example, when **hlj** is an alias, *hlj@posix.com* does not trigger the alias substitution. If no arguments are given, write a listing of the current aliases to standard output. If only an *alias* argument is given, write a listing of the specified alias to standard output. These listings need not reflect the same order of addresses that were entered.

Declare Alternatives

Synopsis: `alt[ernates]` *`name...`*

(See also the **metoo** variable.) Declare a list of alternative names for the user's login. When responding to a message, these names shall be removed from the list of recipients for the response. The comparison of names shall be in a case-insensitive manner. With no arguments, **alternates** shall write the current list of alternative names.

Change Current Directory

Synopsis: `cd [`*`directory`*`]`
`ch[dir] [`*`directory`*`]`

Change directory. If *directory* is not specified, the contents of *HOME* shall be used.

Copy Messages

Synopsis: `c[opy] [`*`file`*`]`
`c[opy] [`*`msglist`*`]` *`file`*
`C[opy] [`*`msglist`*`]`

Copy messages to the file named by the pathname *file* without marking the messages as saved. Otherwise, it shall be equivalent to the **save** command.

In the capitalized form, save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise, it shall be equivalent to the **Save** command.

97935 **Delete Messages**

97936 *Synopsis*: `d[elete] [`*msglist*`]`

97937 Mark messages for deletion from the mailbox. The deletions shall not occur until *mailx* quits (see
97938 the **quit** command) or changes mailboxes (see the **folder** command). If **autoprint** is set and there
97939 are messages remaining after the **delete** command, the current message shall be written as
97940 described for the **print** command (see the **print** command); otherwise, the *mailx* prompt shall be
97941 written.

97942 **Discard Header Fields**

97943 *Synopsis*: `di[scard] [`*header-field*`...]`
97944 `ig[nore] [`*header-field*`...]`

97945 Suppress the specified header fields when writing messages. Specified *header-fields* shall be
97946 added to the list of suppressed header fields. Examples of header fields to ignore are **status** and
97947 **cc**. The fields shall be included when the message is saved. The **Print** and **Type** commands shall
97948 override this command. The comparison of header fields shall be in a case-insensitive manner. If
97949 no arguments are specified, write a list of the currently suppressed header fields to standard
97950 output; the listing need not reflect the same order of header fields that were entered.

97951 If both **retain** and **discard** commands are given, **discard** commands shall be ignored.

97952 **Delete Messages and Display**

97953 *Synopsis*: `dp [`*msglist*`]`
97954 `dt [`*msglist*`]`

97955 Delete the specified messages as described for the **delete** command, except that the **autoprint**
97956 variable shall have no effect, and the current message shall be written only if it was set to a
97957 message after the last message deleted by the command. Otherwise, an informational message
97958 to the effect that there are no further messages in the mailbox shall be written, followed by the
97959 *mailx* prompt.

97960 **Echo a String**

97961 *Synopsis*: `ec[ho]` *string* `...`

97962 Echo the given strings, equivalent to the shell *echo* utility.

97963 **Edit Messages**

97964 *Synopsis*: `e[dit] [`*msglist*`]`

97965 Edit the given messages. The messages shall be placed in a temporary file and the utility named
97966 by the *EDITOR* variable is invoked to edit each file in sequence. The default *EDITOR* is
97967 unspecified.

97968 The **edit** command does not modify the contents of those messages in the mailbox.

97969 **Exit**

97970 *Synopsis*: `ex[it]`
97971 `x[it]`

97972 Exit from *mailx* without changing the mailbox. No messages shall be saved in the **mbox** (see also
97973 **quit**).

97974 **Change Folder**

97975 *Synopsis*: `fi[le] [`*`file`*`]`
97976 `fold[er] [`*`file`*`]`

97977 Quit (see the **quit** command) from the current file of messages and read in the file named by the
97978 pathname *file*. If no argument is given, the name and status of the current mailbox shall be
97979 written.

97980 Several unquoted special characters shall be recognized when used as *file* names, with the
97981 following substitutions:

97982 `%` The system mailbox for the invoking user.

97983 `%`*`user`* The system mailbox for *user*.

97984 `#` The previous file.

97985 `&` The current **mbox**.

97986 `+`*`file`* The named file in the **folder** directory. (See the **folder** variable.)

97987 The default file shall be the current mailbox.

97988 **Display List of Folders**

97989 *Synopsis*: `folders`

97990 Write the names of the files in the directory set by the **folder** variable. The command specified
97991 by the *LISTER* environment variable shall be used (see the ENVIRONMENT VARIABLES
97992 section).

97993 **Follow Up Specified Messages**

97994 *Synopsis*: `fo[llowup] [`*`message`*`]`
97995 `F[ollowup] [`*`msglist`*`]`

97996 In the lowercase form, respond to a message, recording the response in a file whose name is
97997 derived from the author of the message. See also the **save** and **copy** commands and **outfolder**.

97998 In the capitalized form, respond to the first message in the *msglist*, sending the message to the
97999 author of each message in the *msglist*. The subject line shall be taken from the first message and
98000 the response shall be recorded in a file whose name is derived from the author of the first
98001 message. See also the **Save** and **Copy** commands and **outfolder**.

98002 Both forms shall override the **record** variable, if set.

98003 **Display Header Summary for Specified Messages**

98004 *Synopsis*: `f[rom] [`*`msglist`*`]`

98005 Write the header summary for the specified messages.

98006 **Display Header Summary**

98007 *Synopsis*: `h[eaders] [`*`message`*`]`

98008 Write the page of headers that includes the message specified. If the *message* argument is not
98009 specified, the current message shall not change. However, if the *message* argument is specified,
98010 the current message shall become the message that appears at the top of the page of headers that
98011 includes the message specified. The **screen** variable sets the number of headers per page. See
98012 also the **z** command.

98013 **Help**

98014 *Synopsis*: `hel[p]`
98015 `?`

98016 Write a summary of commands.

98017 **Hold Messages**

98018 *Synopsis*: `ho[ld] [`*`msglist`*`]`
98019 `pre[serve] [`*`msglist`*`]`

98020 Mark the messages in *msglist* to be retained in the mailbox when *mailx* terminates. This shall
98021 override any commands that might previously have marked the messages to be deleted. During
98022 the current invocation of *mailx*, only the **delete**, **dp**, or **dt** commands shall remove the *preserve*
98023 marking of a message.

98024 **Execute Commands Conditionally**

98025 *Synopsis*: `i[f] s|r`
98026 *`mail-commands`*
98027 `el[se]`
98028 *`mail-commands`*
98029 `en[dif]`

98030 Execute commands conditionally, where **if s** executes the following *mail-command*s, up to an
98031 **else** or **endif**, if the program is in Send Mode, and **if r** shall cause the *mail-command*s to be
98032 executed only in Receive Mode.

98033 **List Available Commands**

98034 *Synopsis*: `l[ist]`

98035 Write a list of all commands available. No explanation shall be given.

98036 **Mail a Message**

98037 *Synopsis*: `m[ail] address...`

98038 Mail a message to the specified addresses or aliases.

98039 **Direct Messages to mbox**

98040 *Synopsis*: `mb[ox] [msglist]`

98041 Arrange for the given messages to end up in the **mbox** save file when *mailx* terminates normally.
98042 See *MBOX*. See also the **exit** and **quit** commands.

98043 **Process Next Specified Message**

98044 *Synopsis*: `n[ext] [message]`

98045 If the current message has not been written (for example, by the **print** command) since *mailx*
98046 started or since any other message was the current message, behave as if the **print** command
98047 was entered. Otherwise, if there is an undeleted message after the current message, make it the
98048 current message and behave as if the **print** command was entered. Otherwise, an informational
98049 message to the effect that there are no further messages in the mailbox shall be written, followed
98050 by the *mailx* prompt. Should the current message location be the result of an immediately
98051 preceding **hold**, **mbox**, **preserve**, or **touch** command, **next** will act as if the current message has
98052 already been written.

98053 **Pipe Message**

98054 *Synopsis*: `pi[pe] [[msglist] command]`
98055 `| [[msglist] command]`

98056 Pipe the messages through the given *command* by invoking the command interpreter specified
98057 by *SHELL* with two arguments: **−c** and *command*. (See also *sh* **−c**.) The application shall ensure
98058 that the command is given as a single argument. Quoting, described previously, can be used to
98059 accomplish this. If no arguments are given, the current message shall be piped through the
98060 command specified by the value of the **cmd** variable. If the **page** variable is set, a <form-feed>
98061 shall be inserted after each message.

98062 **Display Message with Headers**

98063 *Synopsis*: `P[rint] [msglist]`
98064 `T[ype] [msglist]`

98065 Write the specified messages, including all header lines, to standard output. Override
98066 suppression of lines by the **discard**, **ignore**, and **retain** commands. If **crt** is set, the messages
98067 longer than the number of lines specified by the **crt** variable shall be paged through the
98068 command specified by the *PAGER* environment variable.

98069 **Display Message**

98070 *Synopsis*: `p[rint] [msglist]`
98071 `t[ype] [msglist]`

98072 Write the specified messages to standard output. If **crt** is set, the messages longer than the
98073 number of lines specified by the **crt** variable shall be paged through the command specified by
98074 the *PAGER* environment variable.

98075 **Quit**

98076 *Synopsis*: `q[uit]`
98077 `end-of-file`

98078 Terminate *mailx*, storing messages that were read in **mbox** (if the current mailbox is the system
98079 mailbox and unless **hold** is set), deleting messages that have been explicitly saved (unless
98080 **keepsave** is set), discarding messages that have been deleted, and saving all remaining messages
98081 in the mailbox.

98082 **Reply to a Message List**

98083 *Synopsis*: `R[eply] [msglist]`
98084 `R[espond] [msglist]`

98085 Mail a reply message to the sender of each message in the *msglist*. The subject line shall be
98086 formed by concatenating **Re:**<space> (unless it already begins with that string) and the subject
98087 from the first message. If **record** is set to a filename, the response shall be saved at the end of that
98088 file.

98089 See also the **flipr** variable.

98090 **Reply to a Message**

98091 *Synopsis*: `r[eply] [message]`
98092 `r[espond] [message]`

98093 Mail a reply message to all recipients included in the header of the message. The subject line
98094 shall be formed by concatenating **Re:**<space> (unless it already begins with that string) and the
98095 subject from the message. If **record** is set to a filename, the response shall be saved at the end of
98096 that file.

98097 See also the **flipr** variable.

98098 **Retain Header Fields**

98099 *Synopsis*: `ret[ain] [header-field...]`

98100 Retain the specified header fields when writing messages. This command shall override all
98101 **discard** and **ignore** commands. The comparison of header fields shall be in a case-insensitive
98102 manner. If no arguments are specified, write a list of the currently retained header fields to
98103 standard output; the listing need not reflect the same order of header fields that were entered.

98104 **Save Messages**

98105 *Synopsis*: `s[ave] [file]`
98106 `s[ave] [msglist] file`
98107 `S[ave] [msglist]`

98108 Save the specified messages in the file named by the pathname *file*, or the **mbox** if the *file*
98109 argument is omitted. The file shall be created if it does not exist; otherwise, the messages shall be
98110 appended to the file. The message shall be put in the state *saved*, and shall behave as specified in
98111 the description of the *saved* state when the current mailbox is exited by the **quit** or **file**
98112 command.

98113 In the capitalized form, save the specified messages in a file whose name is derived from the
98114 author of the first message. The name of the file shall be taken to be the author's name with all
98115 network addressing stripped off. See also the **Copy**, **followup**, and **Followup** commands and

98116 **outfolder** variable.

98117 **Set Variables**

98118 *Synopsis*: `se[t] [name[=[string]] ...] [name=number ...] [noname ...]`

98119 Define one or more variables called *name*. The variable can be given a null, string, or numeric
98120 value. Quoting and <backslash>-escapes can occur anywhere in *string*, as described previously,
98121 as if the *string* portion of the argument were the entire argument. The forms *name* and *name*=
98122 shall be equivalent to *name*="" for variables that take string values. The **set** command without
98123 arguments shall write a list of all defined variables and their values. The **no** *name* form shall be
98124 equivalent to **unset** *name*.

98125 **Invoke a Shell**

98126 *Synopsis*: `sh[ell]`

98127 Invoke an interactive command interpreter (see also *SHELL*).

98128 **Display Message Size**

98129 *Synopsis*: `si[ze] [msglist]`

98130 Write the size in bytes of each of the specified messages.

98131 **Read mailx Commands From a File**

98132 *Synopsis*: `so[urce] file`

98133 Read and execute commands from the file named by the pathname *file* and return to command
98134 mode.

98135 **Display Beginning of Messages**

98136 *Synopsis*: `to[p] [msglist]`

98137 Write the top few lines of each of the specified messages. If the **toplines** variable is set, it is taken
98138 as the number of lines to write. The default shall be 5.

98139 **Touch Messages**

98140 *Synopsis*: `tou[ch] [msglist]`

98141 Touch the specified messages. If any message in *msglist* is not specifically deleted nor saved in a
98142 file, it shall be placed in the **mbox** upon normal termination. See **exit** and **quit**.

98143 **Delete Aliases**

98144 *Synopsis*: `una[lias] [alias]...`

98145 Delete the specified alias names. If a specified alias does not exist, the results are unspecified.

98146 **Undelete Messages**

98147 *Synopsis*: `u[ndelete] [`*`msglist`*`]`

98148 Change the state of the specified messages from deleted to read. If **autoprint** is set, the last
98149 message of those restored shall be written. If *msglist* is not specified, the message shall be
98150 selected as follows:

98151 If there are any deleted messages that follow the current message, the first of these shall be
98152 chosen.

98153 Otherwise, the last deleted message that also precedes the current message shall be chosen.

98154 **Unset Variables**

98155 *Synopsis*: `uns[et]` *`name...`*

98156 Cause the specified variables to be erased.

98157 **Edit Message with Full-Screen Editor**

98158 *Synopsis*: `v[isual] [`*`msglist`*`]`

98159 Edit the given messages with a screen editor. Each message shall be placed in a temporary file,
98160 and the utility named by the *VISUAL* variable shall be invoked to edit each file in sequence. The
98161 default editor shall be *vi*.

98162 The **visual** command does not modify the contents of those messages in the mailbox.

98163 **Write Messages to a File**

98164 *Synopsis*: `w[rite] [`*`msglist`*`]` *`file`*

98165 Write the given messages to the file specified by the pathname *file*, minus the message header.
98166 Otherwise, it shall be equivalent to the **save** command.

98167 **Scroll Header Display**

98168 *Synopsis*: `z[+|-]`

98169 Scroll the header display forward (if `'+'` is specified or if no option is specified) or backward (if
98170 `'-'` is specified) one screenful. The number of headers written shall be set by the **screen**
98171 variable.

98172 **Invoke Shell Command**

98173 *Synopsis*: `!`*`command`*

98174 Invoke the command interpreter specified by *SHELL* with two arguments: **-c** and *command*. (See
98175 also *sh* **-c**.) If the **bang** variable is set, each unescaped occurrence of `'!'` in *command* shall be
98176 replaced with the command executed by the previous **!** command or **~!** command escape.

98177 **Null Command**

98178 *Synopsis*: `# comment`

98179 This null command (comment) shall be ignored by *mailx*.

98180 **Display Current Message Number**

98181 *Synopsis*: `=`

98182 Write the current message number.

98183 **Command Escapes in mailx**

98184 The following commands can be entered only from input mode, by beginning a line with the
98185 escape character (by default, <tilde> (`'~'`)). See the **escape** variable description for changing
98186 this special character. The format for the commands shall be:

98187 `<escape-character><command-char><separator>[<arguments>]`

98188 where the <*separator*> can be zero or more <blank> characters.

98189 In the following descriptions, the application shall ensure that the argument *command* (but not
98190 *mailx-command)* is a shell command string. Any string acceptable to the command interpreter
98191 specified by the *SHELL* variable when it is invoked as *SHELL* **−c** *command_string* shall be valid.
98192 The command can be presented as multiple arguments (that is, quoting is not required).

98193 Command escapes that are listed with *msglist* or *mailx-command* arguments are invalid in Send
98194 Mode and produce unspecified results.

98195 **~!** *command* Invoke the command interpreter specified by *SHELL* with two arguments: **−c** and
98196 *command*; and then return to input mode. If the **bang** variable is set, each
98197 unescaped occurrence of `'!'` in *command* shall be replaced with the command
98198 executed by the previous **!** command or **~!** command escape.

98199 **~.** Simulate end-of-file (terminate message input).

98200 **~:** *mailx-command*, **~_** *mailx-command*
98201 Perform the command-level request.

98202 **~?** Write a summary of command escapes.

98203 **~A** This shall be equivalent to **~i Sign**.

98204 **~a** This shall be equivalent to **~i sign**.

98205 **~b** *name*... Add the *name*s to the blind carbon copy (**Bcc**) list.

98206 **~c** *name*... Add the *name*s to the carbon copy (**Cc**) list.

98207 **~d** Read in the dead-letter file. See *DEAD* for a description of this file.

98208 **~e** Invoke the editor, as specified by the *EDITOR* environment variable, on the partial
98209 message.

98210 **~f** [*msglist*] Forward the specified messages. The specified messages shall be inserted into the
98211 current message without alteration. This command escape also shall insert
98212 message headers into the message with field selection affected by the **discard**,
98213 **ignore**, and **retain** commands.

98214 **~F** [*msglist*] This shall be the equivalent of the **~f** command escape, except that all headers shall
98215 be included in the message, regardless of previous **discard**, **ignore**, and **retain**
98216 commands.

98217 **~h** If standard input is a terminal, prompt for a **Subject** line and the **To**, **Cc**, and **Bcc**
98218 lists. Other implementation-defined headers may also be presented for editing. If
98219 the field is written with an initial value, it can be edited as if it had just been typed.

98220 **~i** *string* Insert the value of the named variable, followed by a <newline>, into the text of
98221 the message. If the string is unset or null, the message shall not be changed.

98222 **~m** [*msglist*] Insert the specified messages into the message, prefixing non-empty lines with the
98223 string in the **indentprefix** variable. This command escape also shall insert message
98224 headers into the message, with field selection affected by the **discard**, **ignore**, and
98225 **retain** commands.

98226 **~M** [*msglist*] This shall be the equivalent of the **~m** command escape, except that all headers
98227 shall be included in the message, regardless of previous **discard**, **ignore**, and **retain**
98228 commands.

98229 **~p** Write the message being entered. If the message is longer than **crt** lines (see
98230 Internal Variables in mailx, on page 2950), the output shall be paginated as
98231 described for the *PAGER* variable.

98232 **~q** Quit (see the **quit** command) from input mode by simulating an interrupt. If the
98233 body of the message is not empty, the partial message shall be saved in the dead-
98234 letter file. See *DEAD* for a description of this file.

98235 **~r** *file*, **~<** *file*, **~r !***command*, **~< !***command*
98236 Read in the file specified by the pathname *file*. If the argument begins with an
98237 <exclamation-mark> (`'!'`), the rest of the string shall be taken as an arbitrary
98238 system command; the command interpreter specified by *SHELL* shall be invoked
98239 with two arguments: **−c** and *command*. The standard output of *command* shall be
98240 inserted into the message.

98241 **~s** *string* Set the subject line to *string*.

98242 **~t** *name*... Add the given *name*s to the **To** list.

98243 **~v** Invoke the full-screen editor, as specified by the *VISUAL* environment variable, on
98244 the partial message.

98245 **~w** *file* Write the partial message, without the header, onto the file named by the
98246 pathname *file*. The file shall be created or the message shall be appended to it if
98247 the file exists.

98248 **~x** Exit as with **~q**, except the message shall not be saved in the dead-letter file.

98249 **~|** *command* Pipe the body of the message through the given *command* by invoking the
98250 command interpreter specified by *SHELL* with two arguments: **−c** and *command*. If
98251 the *command* returns a successful exit status, the standard output of the command
98252 shall replace the message. Otherwise, the message shall remain unchanged. If the
98253 *command* fails, an error message giving the exit status shall be written.

EXIT STATUS

When the **−e** option is specified, the following exit values are returned:

0 Mail was found.

>0 Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0 Successful completion; note that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When in input mode (Receive Mode) or Send Mode:

If an error is encountered processing an input line beginning with a <tilde> ('~') character, (see Command Escapes in mailx, on page 2962), a diagnostic message shall be written to standard error, and the message being composed may be modified, but this condition shall not prevent the message from being sent.

Other errors shall prevent the sending of the message.

When in command mode:

Default.

APPLICATION USAGE

Delivery of messages to remote systems requires the existence of communication paths to such systems. These need not exist.

Input lines are limited to {LINE_MAX} bytes, but mailers between systems may impose more severe line-length restrictions. This volume of POSIX.1-2017 does not place any restrictions on the length of messages handled by *mailx*, and for delivery of local messages the only limitations should be the normal problems of available disk space for the target mail file. When sending messages to external machines, applications are advised to limit messages to less than 100 000 bytes because some mail gateways impose message-length restrictions.

The format of the system mailbox is intentionally unspecified. Not all systems implement system mailboxes as flat files, particularly with the advent of multimedia mail messages. Some system mailboxes may be multiple files, others records in a database. The internal format of the messages themselves is specified with the historical format from Version 7, but only after the messages have been saved in some file other than the system mailbox. This was done so that many historical applications expecting text-file mailboxes are not broken.

Some new formats for messages can be expected in the future, probably including binary data, bit maps, and various multimedia objects. As described here, *mailx* is not prohibited from handling such messages, but it must store them as text files in secondary mailboxes (unless some extension, such as a variable or command line option, is used to change the stored format). Its method of doing so is implementation-defined and might include translating the data into text file-compatible or readable form or omitting certain portions of the message from the stored output.

The **discard** and **ignore** commands are not inverses of the **retain** command. The **retain** command discards all header-fields except those explicitly retained. The **discard** command keeps all header-fields except those explicitly discarded. If headers exist on the retained header

98296 list, **discard** and **ignore** commands are ignored.

98297 **EXAMPLES**

98298 None.

98299 **RATIONALE**

98300 The standard developers felt strongly that a method for applications to send messages to specific
98301 users was necessary. The obvious example is a batch utility, running non-interactively, that
98302 wishes to communicate errors or results to a user. However, the actual format, delivery
98303 mechanism, and method of reading the message are clearly beyond the scope of this volume of
98304 POSIX.1-2017.

98305 The intent of this command is to provide a simple, portable interface for sending messages non-
98306 interactively. It merely defines a ``front-end'' to the historical mail system. It is suggested that
98307 implementations explicitly denote the sender and recipient in the body of the delivered message.
98308 Further specification of formats for either the message envelope or the message itself were
98309 deliberately not made, as the industry is in the midst of changing from the current standards to a
98310 more internationalized standard and it is probably incorrect, at this time, to require either one.

98311 Implementations are encouraged to conform to the various delivery mechanisms described in
98312 the CCITT X.400 standards or to the equivalent Internet standards, described in Internet Request
98313 for Comment (RFC) documents RFC 819, RFC 920, RFC 921, RFC 1123, and RFC 5322 (which
98314 succeeded RFC 822).

98315 Many historical systems modified each body line that started with **From** by prefixing the `'F'`
98316 with `'>'`. It is unnecessary, but allowed, to do that when the string does not follow a blank line
98317 because it cannot be confused with the next header.

98318 The **edit** and **visual** commands merely edit the specified messages in a temporary file. They do
98319 not modify the contents of those messages in the mailbox; such a capability could be added as an
98320 extension, such as by using different command names.

98321 The restriction on a subject line being {LINE_MAX}–10 bytes is based on the historical format
98322 that consumes 10 bytes for **Subject:** and the trailing <newline>. Many historical mailers that a
98323 message may encounter on other systems are not able to handle lines that long, however.

98324 Like the utilities *logger* and *lp*, *mailx* admittedly is difficult to test. This was not deemed sufficient
98325 justification to exclude this utility from this volume of POSIX.1-2017. It is also arguable that it is,
98326 in fact, testable, but that the tests themselves are not portable.

98327 When *mailx* is being used by an application that wishes to receive the results as if none of the
98328 User Portability Utilities option features were supported, the *DEAD* environment variable must
98329 be set to **/dev/null**. Otherwise, it may be subject to the file creations described in *mailx*
98330 ASYNCHRONOUS EVENTS. Similarly, if the *MAILRC* environment variable is not set to
98331 **/dev/null**, historical versions of *mailx* and *Mail* read initialization commands from a file before
98332 processing begins. Since the initialization that a user specifies could alter the contents of
98333 messages an application is trying to send, such applications must set *MAILRC* to **/dev/null**.

98334 The description of *LC_TIME* uses ``may affect'' because many historical implementations do not
98335 or cannot manipulate the date and time strings in the incoming mail headers. Some headers
98336 found in incoming mail do not have enough information to determine the timezone in which the
98337 mail originated, and, therefore, *mailx* cannot convert the date and time strings into the internal
98338 form that then is parsed by routines like *strftime*() that can take *LC_TIME* settings into account.
98339 Changing all these times to a user-specified format is allowed, but not required.

98340 The paginator selected when *PAGER* is null or unset is partially unspecified to allow the System
98341 V historical practice of using *pg* as the default. Bypassing the pagination function, such as by

98342 declaring that *cat* is the paginator, would not meet with the intended meaning of this
98343 description. However, any ``portable user'' would have to set *PAGER* explicitly to get his or her
98344 preferred paginator on all systems. The paginator choice was made partially unspecified, unlike
98345 the *VISUAL* editor choice (mandated to be *vi*) because most historical pagers follow a common
98346 theme of user input, whereas editors differ dramatically.

98347 Options to specify addresses as **cc** (carbon copy) or **bcc** (blind carbon copy) were considered to
98348 be format details and were omitted.

98349 A zero exit status implies that all messages were *sent*, but it gives no assurances that any of them
98350 were actually *delivered*. The reliability of the delivery mechanism is unspecified and is an
98351 appropriate marketing distinction between systems.

98352 In order to conform to the Utility Syntax Guidelines, a solution was required to the optional *file*
98353 option-argument to **−f**. By making *file* an operand, the guidelines are satisfied and users remain
98354 portable. However, it does force implementations to support usage such as:

98355 `mailx −fin mymail.box`

98356 The **no** *name* method of unsetting variables is not present in all historical systems, but it is in
98357 System V and provides a logical set of commands corresponding to the format of the display of
98358 options from the *mailx set* command without arguments.

98359 The **ask** and **asksub** variables are the names selected by BSD and System V, respectively, for the
98360 same feature. They are synonyms in this volume of POSIX.1-2017.

98361 The *mailx echo* command was not documented in the BSD version and has been omitted here
98362 because it is not obviously useful for interactive users.

98363 The default prompt on the System V *mailx* is a <question-mark>, on BSD *Mail* an <ampersand>.
98364 Since this volume of POSIX.1-2017 chose the *mailx* name, it kept the System V default, assuming
98365 that BSD users would not have difficulty with this minor incompatibility (that they can
98366 override).

98367 The meanings of **r** and **R** are reversed between System V *mailx* and SunOS *Mail*. Once again,
98368 since this volume of POSIX.1-2017 chose the *mailx* name, it kept the System V default, but allows
98369 the SunOS user to achieve the desired results using **flipr**, an internal variable in System V *mailx*,
98370 although it has not been documented in the SVID.

98371 The **indentprefix** variable, the **retain** and **unalias** commands, and the **~F** and **~M** command
98372 escapes were adopted from 4.3 BSD *Mail*.

98373 The **version** command was not included because no sufficiently general specification of the
98374 version information could be devised that would still be useful to a portable user. This
98375 command name should be used by suppliers who wish to provide version information about the
98376 *mailx* command.

98377 The ``implementation-specific (unspecified) system start-up file'' historically has been named
98378 **/etc/mailx.rc**, but this specific name and location are not required.

98379 The intent of the wording for the **next** command is that if any command has already displayed
98380 the current message it should display a following message, but, otherwise, it should display the
98381 current message. Consider the command sequence:

98382 ```
98383 next 3
98384 delete 3
98384 next
```

98385 where the **autoprint** option was not set. The normative text specifies that the second **next**

  
```

command should display a message following the third message, because even though the current message has not been displayed since it was set by the **delete** command, it has been displayed since the current message was anything other than message number 3. This does not always match historical practice in some implementations, where the command file address followed by **next** (or the default command) would skip the message for which the user had searched.

FUTURE DIRECTIONS

None.

SEE ALSO

Chapter 2 (on page 2345), *ed*, *ls*, *more*, *vi*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The description of the *EDITOR* environment variable is changed to indicate that *ed* is the default editor if this variable is not set. In previous issues, this default was not stated explicitly at this point but was implied further down in the text.

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

The **–F** option is added.

The **allnet**, **debug**, and **sendwait** internal variables are added.

The **C**, **ec**, **fo**, **F**, and **S** *mailx* commands are added.

In the DESCRIPTION and ENVIRONMENT VARIABLES sections, text stating ``*HOME* directory'' is replaced by ``directory referred to by the *HOME* environment variable''.

The *mailx* utility is aligned with the IEEE P1003.2b draft standard, which includes various clarifications to resolve IEEE PASC Interpretations submitted for the ISO POSIX-2:1993 standard. In particular, the changes here address IEEE PASC Interpretations 1003.2 #10, #11, #103, #106, #108, #114, #115, #122, and #129.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/32 is applied, applying a change to the EXTENDED DESCRIPTION, raised by IEEE PASC Interpretation 1003.2 #122, which was overlooked in the first version of this standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/17 is applied, updating the EXTENDED DESCRIPTION (Internal Variables in *mailx*). The system start-up file is changed from ``implementation-defined'' to ``unspecified'' for consistency with other text in the EXTENDED DESCRIPTION.

Issue 7

Austin Group Interpretation 1003.1-2001 #089 is applied, clarifying the effect of the *LC_TIME* environment variable.

Austin Group Interpretation 1003.1-2001 #090 is applied, updating the description of the **next**

command.

SD5-XCU-ERN-69 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Shading to indicate support for the User Portability Utilities option is added.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0120 [855] and XCU/TC2-2008/0121 [619] are applied.

NAME

make — maintain, update, and regenerate groups of programs (**DEVELOPMENT**)

SYNOPSIS

SD
```
make [−einpqrst] [−f makefile]... [−k|−S] [macro=value...]
    [target_name...]
```

DESCRIPTION

The *make* utility shall update files that are derived from other files. A typical case is one where object files are derived from the corresponding source files. The *make* utility examines time relationships and shall update those derived files (called targets) that have modified times earlier than the modified times of the files (called prerequisites) from which they are derived. A description file (makefile) contains a description of the relationships between files, and the commands that need to be executed to update the targets to reflect changes in their prerequisites. Each specification, or rule, shall consist of a target, optional prerequisites, and optional commands to be executed when a prerequisite is newer than the target. There are two types of rule:

1. *Inference rules*, which have one target name with at least one <period> (`'.'`) and no <slash> (`'/'`)
2. *Target rules*, which can have more than one target name

In addition, *make* shall have a collection of built-in macros and inference rules that infer prerequisite relationships to simplify maintenance of programs.

To receive exactly the behavior described in this section, the user shall ensure that a portable makefile shall:

> Include the special target **.POSIX**
>
> Omit any special target reserved for implementations (a leading period followed by uppercase letters) that has not been specified by this section

The behavior of *make* is unspecified if either or both of these conditions are not met.

OPTIONS

The *make* utility shall conform to XBD Section 12.2 (on page 216), except for Guideline 9.

The following options shall be supported:

−e Cause environment variables, including those with null values, to override macro assignments within makefiles.

−f *makefile* Specify a different makefile. The argument *makefile* is a pathname of a description file, which is also referred to as the *makefile*. A pathname of `'−'` shall denote the standard input. There can be multiple instances of this option, and they shall be processed in the order specified. The effect of specifying the same option-argument more than once is unspecified.

−i Ignore error codes returned by invoked commands. This mode is the same as if the special target **.IGNORE** were specified without prerequisites.

−k Continue to update other targets that do not depend on the current target if a non-ignored error occurs while executing the commands to bring a target up-to-date.

−n Write commands that would be executed on standard output, but do not execute them. However, lines with a <plus-sign> (`'+'`) prefix shall be executed. In this mode, lines with an at-sign (`'@'`) character prefix shall be written to standard

output.

−p Write to standard output the complete set of macro definitions and target descriptions. The output format is unspecified.

−q Return a zero exit value if the target file is up-to-date; otherwise, return an exit value of 1. Targets shall not be updated if this option is specified. However, a makefile command line (associated with the targets) with a <plus-sign> (`'+'`) prefix shall be executed.

−r Clear the suffix list and do not use the built-in rules.

−S Terminate *make* if an error occurs while executing the commands to bring a target up-to-date. This shall be the default and the opposite of **−k**.

−s Do not write makefile command lines or touch messages (see **−t**) to standard output before executing. This mode shall be the same as if the special target **.SILENT** were specified without prerequisites.

−t Update the modification time of each target as though a *touch target* had been executed. Targets that have prerequisites but no commands (see Target Rules, on page 2974), or that are already up-to-date, shall not be touched in this manner. Write messages to standard output for each target file indicating the name of the file and that it was touched. Normally, the *makefile* command lines associated with each target are not executed. However, a command line with a <plus-sign> (`'+'`) prefix shall be executed.

Any options specified in the *MAKEFLAGS* environment variable shall be evaluated before any options specified on the *make* utility command line. If the **−k** and **−S** options are both specified on the *make* utility command line or by the *MAKEFLAGS* environment variable, the last option specified shall take precedence. If the **−f** or **−p** options appear in the *MAKEFLAGS* environment variable, the result is undefined.

OPERANDS

The following operands shall be supported:

target_name Target names, as defined in the EXTENDED DESCRIPTION section. If no target is specified, while *make* is processing the makefiles, the first target that *make* encounters that is not a special target or an inference rule shall be used.

macro=value Macro definitions, as defined in Macros (on page 2976).

If the *target_name* and *macro=value* operands are intermixed on the *make* utility command line, the results are unspecified.

STDIN

The standard input shall be used only if the *makefile* option-argument is `'−'`. See the INPUT FILES section.

INPUT FILES

The input file, otherwise known as the makefile, is a text file containing rules, macro definitions, include lines, and comments. See the EXTENDED DESCRIPTION section.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *make*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

98522 *LC_ALL* If set to a non-empty string value, override the values of all the other
98523 internationalization variables.

98524 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
98525 characters (for example, single-byte as opposed to multi-byte characters in
98526 arguments and input files).

98527 *LC_MESSAGES*
98528 Determine the locale that should be used to affect the format and contents of
98529 diagnostic messages written to standard error.

98530 *MAKEFLAGS*
98531 This variable shall be interpreted as a character string representing a series of
98532 option characters to be used as the default options. The implementation shall
98533 accept both of the following formats (but need not accept them when intermixed):

98534 The characters are option letters without the leading <hyphen-minus>
98535 characters or <blank> separation used on a *make* utility command line.

98536 The characters are formatted in a manner similar to a portion of the *make*
98537 utility command line: options are preceded by <hyphen-minus> characters
98538 and <blank>-separated as described in XBD Section 12.2 (on page 216). The
98539 *macro=value* macro definition operands can also be included. The difference
98540 between the contents of *MAKEFLAGS* and the *make* utility command line is
98541 that the contents of the variable shall not be subjected to the word expansions
98542 (see Section 2.6, on page 2353) associated with parsing the command line
98543 values.

98544 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

98545 XSI *PROJECTDIR*
98546 Provide a directory to be used to search for SCCS files not found in the current
98547 directory. In all of the following cases, the search for SCCS files is made in the
98548 directory **SCCS** in the identified directory. If the value of *PROJECTDIR* begins with
98549 a <slash>, it shall be considered an absolute pathname; otherwise, the value of
98550 *PROJECTDIR* is treated as a user name and that user's initial working directory
98551 shall be examined for a subdirectory **src** or **source**. If such a directory is found, it
98552 shall be used. Otherwise, the value is used as a relative pathname.

98553 If *PROJECTDIR* is not set or has a null value, the search for SCCS files shall be
98554 made in the directory **SCCS** in the current directory.

98555 The setting of *PROJECTDIR* affects all files listed in the remainder of this utility
98556 description for files with a component named **SCCS**.

98557 The value of the *SHELL* environment variable shall not be used as a macro and shall not be
98558 modified by defining the **SHELL** macro in a makefile or on the command line. All other
98559 environment variables, including those with null values, shall be used as macros, as defined in
98560 Macros (on page 2976).

98561 **ASYNCHRONOUS EVENTS**
98562 If not already ignored, *make* shall trap SIGHUP, SIGTERM, SIGINT, and SIGQUIT and remove
98563 the current target unless the target is a directory or the target is a prerequisite of the special
98564 target **.PRECIOUS** or unless one of the **−n**, **−p**, or **−q** options was specified. Any targets removed
98565 in this manner shall be reported in diagnostic messages of unspecified format, written to
98566 standard error. After this cleanup process, if any, *make* shall take the standard action for all other
98567 signals.

98568 **STDOUT**

98569 The *make* utility shall write all commands to be executed to standard output unless the **−s** option
98570 was specified, the command is prefixed with an at-sign, or the special target **.SILENT** has either
98571 the current target as a prerequisite or has no prerequisites. If *make* is invoked without any work
98572 needing to be done, it shall write a message to standard output indicating that no action was
98573 taken. If the **−t** option is present and a file is touched, *make* shall write to standard output a
98574 message of unspecified format indicating that the file was touched, including the filename of the
98575 file.

98576 **STDERR**

98577 The standard error shall be used only for diagnostic messages.

98578 **OUTPUT FILES**

98579 Files can be created when the **−t** option is present. Additional files can also be created by the
98580 utilities invoked by *make*.

98581 **EXTENDED DESCRIPTION**

98582 The *make* utility attempts to perform the actions required to ensure that the specified targets are
98583 up-to-date. A target shall be considered up-to-date if it exists and is newer than all of its
98584 dependencies, or if it has already been made up-to-date by the current invocation of *make*
98585 (regardless of the target's existence or age). A target may also be considered up-to-date if it
98586 exists, is the same age as one or more of its prerequisites, and is newer than the remaining
98587 prerequisites (if any). The *make* utility shall treat all prerequisites as targets themselves and
98588 recursively ensure that they are up-to-date, processing them in the order in which they appear in
98589 the rule. The *make* utility shall use the modification times of files to determine whether the
98590 corresponding targets are out-of-date.

98591 To ensure that a target is up-to-date, *make* shall ensure that all of the prerequisites of a target are
98592 up-to-date, then check to see if the target itself is up-to-date. If the target is not up-to-date, the
98593 target shall be made up-to-date by executing the rule's commands (if any). If the target does not
98594 exist after the target has been successfully made up-to-date, the target shall be treated as being
98595 newer than any target for which it is a prerequisite.

98596 If a target exists and there is neither a target rule nor an inference rule for the target, the target
98597 shall be considered up-to-date. It shall be an error if *make* attempts to ensure that a target is up-
98598 to-date but the target does not exist and there is neither a target rule nor an inference rule for the
98599 target.

98600 **Makefile Syntax**

98601 A makefile can contain rules, macro definitions (see Macros, on page 2976), include lines, and
98602 comments. There are two kinds of rules: *inference rules* and *target rules*. The *make* utility shall
98603 contain a set of built-in inference rules. If the **−r** option is present, the built-in rules shall not be
98604 used and the suffix list shall be cleared. Additional rules of both types can be specified in a
98605 makefile. If a rule is defined more than once, the value of the rule shall be that of the last one
98606 specified. Macros can also be defined more than once, and the value of the macro is specified in
98607 Macros (on page 2976). There are three kinds of comments: blank lines, empty lines, and a
98608 <number-sign> (`'#'`) and all following characters up to the first unescaped <newline>
98609 character. Blank lines, empty lines, and lines with <number-sign> (`'#'`) as the first character on
98610 the line are also known as comment lines.

98611 By default, the following files shall be tried in sequence: **./makefile** and **./Makefile**. If neither
98612 XSI **./makefile** or **./Makefile** are found, other implementation-defined files may also be tried. On
98613 XSI-conformant systems, the additional files **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and
98614 **SCCS/s.Makefile** shall also be tried.

The **−f** option shall direct *make* to ignore any of these default files and use the specified argument as a makefile instead. If the `'−'` argument is specified, standard input shall be used.

The term *makefile* is used to refer to any rules provided by the user, whether in **./makefile** or its variants, or specified by the **−f** option.

The rules in makefiles shall consist of the following types of lines: target rules, including special targets (see Target Rules, on page 2974), inference rules (see Inference Rules, on page 2977), macro definitions (see Macros, on page 2976), and comments.

Target and Inference Rules may contain *command lines*. Command lines can have a prefix that shall be removed before execution (see Makefile Execution, on page 2974).

When an escaped <newline> (one preceded by a <backslash>) is found anywhere in the makefile except in a command line, an include line, or a line immediately preceding an include line, it shall be replaced, along with any leading white space on the following line, with a single <space>. When an escaped <newline> is found in a command line in a makefile, the command line shall contain the <backslash>, the <newline>, and the next line, except that the first character of the next line shall not be included if it is a <tab>. When an escaped <newline> is found in an include line or in a line immediately preceding an include line, the behavior is unspecified.

Include Lines

If the word **include** appears at the beginning of a line and is followed by one or more <blank> characters, the string formed by the remainder of the line shall be processed as follows to produce a pathname:

The trailing <newline>, any <blank> characters immediately preceding a comment, and any comment shall be discarded. If the resulting string contains any double-quote characters (`'"'`) the behavior is unspecified.

The resulting string shall be processed for macro expansion (see Macros, on page 2976).

Any <blank> characters that appear after the first non-<blank> shall be used as separators to divide the macro-expanded string into fields. It is unspecified whether any other white-space characters are also used as separators. It is unspecified whether pathname expansion (see Section 2.13, on page 2382) is also performed.

If the processing of separators and optional pathname expansion results in either zero or two or more non-empty fields, the behavior is unspecified. If it results in one non-empty field, that field is taken as the pathname.

If the pathname does not begin with a `'/'` it shall be treated as relative to the current working directory of the process, not relative to the directory containing the makefile. If the file does not exist in this location, it is unspecified whether additional directories are searched.

The contents of the file specified by the pathname shall be read and processed as if they appeared in the makefile in place of the include line. If the file ends with an escaped <newline> the behavior is unspecified.

The file may itself contain further include lines. Implementations shall support nesting of include files up to a depth of at least 16.

Makefile Execution

Makefile command lines shall be processed one at a time.

Makefile command lines can have one or more of the following prefixes: a <hyphen-minus> (`'-'`), an at-sign (`'@'`), or a <plus-sign> (`'+'`). These shall modify the way in which *make* processes the command.

- `-` If the command prefix contains a <hyphen-minus>, or the **−i** option is present, or the special target **.IGNORE** has either the current target as a prerequisite or has no prerequisites, any error found while executing the command shall be ignored.
- `@` If the command prefix contains an at-sign and the *make* utility command line **−n** option is not specified, or the **−s** option is present, or the special target **.SILENT** has either the current target as a prerequisite or has no prerequisites, the command shall not be written to standard output before it is executed.
- `+` If the command prefix contains a <plus-sign>, this indicates a makefile command line that shall be executed even if **−n**, **−q**, or **−t** is specified.

An *execution line* is built from the command line by removing any prefix characters. Except as described under the at-sign prefix, the execution line shall be written to the standard output, optionally preceded by a <tab>. The execution line shall then be executed by a shell as if it were passed as the argument to the *system*( ) interface, except that if errors are not being ignored then the shell **−e** option shall also be in effect. If errors are being ignored for the command (as a result of the **−i** option, a `'-'` command prefix, or a **.IGNORE** special target), the shell **−e** option shall not be in effect. The environment for the command being executed shall contain all of the variables in the environment of *make*.

By default, when *make* receives a non-zero status from the execution of a command, it shall terminate with an error message to standard error.

Target Rules

Target rules are formatted as follows:

```
target [target...]: [prerequisite...][;command]
[<tab>command
<tab>command
...]

line that does not begin with <tab>
```

Target entries are specified by a <blank>-separated, non-null list of targets, then a <colon>, then a <blank>-separated, possibly empty list of prerequisites. Text following a <semicolon>, if any, and all following lines that begin with a <tab>, are makefile command lines to be executed to update the target. The first non-empty line that does not begin with a <tab> or `'#'` shall begin a new entry. Any comment line may begin a new entry.

Applications shall select target names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see XBD Section 6.1, on page 125). Implementations may allow other characters in target names as extensions. The interpretation of targets containing the characters `'%'` and `'"'` is implementation-defined.

A target that has prerequisites, but does not have any commands, can be used to add to the prerequisite list for that target. Only one target rule for any given target can contain commands.

Lines that begin with one of the following are called *special targets* and control the operation of *make*:

98699 **.DEFAULT** If the makefile uses this special target, the application shall ensure that it is
98700 specified with commands, but without prerequisites. The commands shall be used
98701 by *make* if there are no other rules available to build a target.

98702 **.IGNORE** Prerequisites of this special target are targets themselves; this shall cause errors
98703 from commands associated with them to be ignored in the same manner as
98704 specified by the **−i** option. Subsequent occurrences of **.IGNORE** shall add to the
98705 list of targets ignoring command errors. If no prerequisites are specified, *make* shall
98706 behave as if the **−i** option had been specified and errors from all commands
98707 associated with all targets shall be ignored.

98708 **.POSIX** The application shall ensure that this special target is specified without
98709 prerequisites or commands. If it appears as the first non-comment line in the
98710 makefile, *make* shall process the makefile as specified by this section; otherwise, the
98711 behavior of *make* is unspecified.

98712 **.PRECIOUS** Prerequisites of this special target shall not be removed if *make* receives one of the
98713 asynchronous events explicitly described in the ASYNCHRONOUS EVENTS
98714 section. Subsequent occurrences of **.PRECIOUS** shall add to the list of precious
98715 files. If no prerequisites are specified, all targets in the makefile shall be treated as
98716 if specified with **.PRECIOUS**.

98717 XSI **.SCCS_GET** The application shall ensure that this special target is specified without
98718 prerequisites. If this special target is included in a makefile, the commands
98719 specified with this target shall replace the default commands associated with this
98720 special target (see Default Rules, on page 2980). The commands specified with this
98721 target are used to get all SCCS files that are not found in the current directory.

98722 When source files are named in a dependency list, *make* shall treat them just like
98723 any other target. Because the source file is presumed to be present in the directory,
98724 there is no need to add an entry for it to the makefile. When a target has no
98725 dependencies, but is present in the directory, *make* shall assume that that file is up-
98726 to-date. If, however, an SCCS file named **SCCS/s.***source_file* is found for a target
98727 *source_file*, *make* compares the timestamp of the target file with that of the
98728 **SCCS/s.source_file** to ensure the target is up-to-date. If the target is missing, or if
98729 the SCCS file is newer, *make* shall automatically issue the commands specified for
98730 the **.SCCS_GET** special target to retrieve the most recent version. However, if the
98731 target is writable by anyone, *make* shall not retrieve a new version.

98732 **.SILENT** Prerequisites of this special target are targets themselves; this shall cause
98733 commands associated with them not to be written to the standard output before
98734 they are executed. Subsequent occurrences of **.SILENT** shall add to the list of
98735 targets with silent commands. If no prerequisites are specified, *make* shall behave
98736 as if the **−s** option had been specified and no commands or touch messages
98737 associated with any target shall be written to standard output.

98738 **.SUFFIXES** Prerequisites of **.SUFFIXES** shall be appended to the list of known suffixes and are
98739 used in conjunction with the inference rules (see Inference Rules, on page 2977). If
98740 **.SUFFIXES** does not have any prerequisites, the list of known suffixes shall be
98741 cleared.

98742 The special targets **.IGNORE**, **.POSIX**, **.PRECIOUS**, **.SILENT**, and **.SUFFIXES** shall be specified
98743 without commands.

98744 Targets with names consisting of a leading <period> followed by the uppercase letters `"POSIX"`
98745 and then any other characters are reserved for future standardization. Targets with names

consisting of a leading <period> followed by one or more uppercase letters are reserved for implementation extensions.

Macros

Macro definitions are in the form:

string1 = **[***string2***]**

The macro named *string1* is defined as having the value of *string2*, where *string2* is defined as all characters, if any, after the <equals-sign>, up to a comment character (`'#'`) or an unescaped <newline>. Any <blank> characters immediately before or after the <equals-sign> shall be ignored.

Applications shall select macro names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see XBD Section 6.1, on page 125). A macro name shall not contain an <equals-sign>. Implementations may allow other characters in macro names as extensions.

Macros can appear anywhere in the makefile. Macro expansions using the forms $(*string1*) or ${*string1*} shall be replaced by *string2*, as follows:

> Macros in target lines shall be evaluated when the target line is read.
>
> Macros in makefile command lines shall be evaluated when the command is executed.
>
> Macros in the string before the <equals-sign> in a macro definition shall be evaluated when the macro assignment is made.
>
> Macros after the <equals-sign> in a macro definition shall not be evaluated until the defined macro is used in a rule or command, or before the <equals-sign> in a macro definition.

The parentheses or braces are optional if *string1* is a single character. The macro $$ shall be replaced by the single character `'$'`. If *string1* in a macro expansion contains a macro expansion, the results are unspecified.

Macro expansions using the forms $(*string1***[:***subst1***=[***subst2***]]**) or ${*string1***[:***subst1***=[***subst2***]]**} can be used to replace all occurrences of *subst1* with *subst2* when the macro substitution is performed. The *subst1* to be replaced shall be recognized when it is a suffix at the end of a word in *string1* (where a *word*, in this context, is defined to be a string delimited by the beginning of the line, a <blank>, or a <newline>). If *string1* in a macro expansion contains a macro expansion, the results are unspecified. If a <percent-sign> character appears as part of *subst1* or *subst2* after any macros have been recursively expanded, the results are unspecified.

Macro expansions in *string1* of macro definition lines shall be evaluated when read. Macro expansions in *string2* of macro definition lines shall be performed when the macro identified by *string1* is expanded in a rule or command.

Macro definitions shall be taken from the following sources, in the following logical order, before the makefile(s) are read.

1. Macros specified on the *make* utility command line, in the order specified on the command line. It is unspecified whether the internal macros defined in Internal Macros (on page 2979) are accepted from this source.
2. Macros defined by the *MAKEFLAGS* environment variable, in the order specified in the environment variable. It is unspecified whether the internal macros defined in Internal Macros (on page 2979) are accepted from this source.

98789 3. The contents of the environment, excluding the *MAKEFLAGS* and *SHELL* variables and
98790 including the variables with null values.

98791 4. Macros defined in the inference rules built into *make*.

98792 Macro definitions from these sources shall not override macro definitions from a lower-
98793 numbered source. Macro definitions from a single source (for example, the *make* utility
98794 command line, the *MAKEFLAGS* environment variable, or the other environment variables)
98795 shall override previous macro definitions from the same source.

98796 Macros defined in the makefile(s) shall override macro definitions that occur before them in the
98797 makefile(s) and macro definitions from source 4. If the **−e** option is not specified, macros defined
98798 in the makefile(s) shall override macro definitions from source 3. Macros defined in the
98799 makefile(s) shall not override macro definitions from source 1 or source 2.

98800 Before the makefile(s) are read, all of the *make* utility command line options (except **−f** and **−p**)
98801 and *make* utility command line macro definitions (except any for the *MAKEFLAGS* macro), not
98802 already included in the *MAKEFLAGS* macro, shall be added to the *MAKEFLAGS* macro, quoted
98803 in an implementation-defined manner such that when *MAKEFLAGS* is read by another instance
98804 of the *make* command, the original macro's value is recovered. Other implementation-defined
98805 options and macros may also be added to the *MAKEFLAGS* macro. If this modifies the value of
98806 the *MAKEFLAGS* macro, or, if the *MAKEFLAGS* macro is modified at any subsequent time, the
98807 *MAKEFLAGS* environment variable shall be modified to match the new value of the
98808 *MAKEFLAGS* macro. The result of setting *MAKEFLAGS* in the Makefile is unspecified.

98809 Before the makefile(s) are read, all of the *make* utility command line macro definitions (except the
98810 *MAKEFLAGS* macro or the *SHELL* macro) shall be added to the environment of *make*. Other
98811 implementation-defined variables may also be added to the environment of *make*. Macros
98812 defined by the *MAKEFLAGS* environment variable and macros defined in the makefile(s) shall
98813 not be added to the environment of *make* if they are not already in its environment. With the
98814 exception of *SHELL* (see below), it is unspecified whether macros defined in these ways update
98815 the value of an environment variable that already exists in the environment of *make*.

98816 The **SHELL** macro shall be treated specially. It shall be provided by *make* and set to the
98817 pathname of the shell command language interpreter (see *sh*). The *SHELL* environment variable
98818 shall not affect the value of the **SHELL** macro. If **SHELL** is defined in the makefile or is specified
98819 on the command line, it shall replace the original value of the **SHELL** macro, but shall not affect
98820 the *SHELL* environment variable. Other effects of defining **SHELL** in the makefile or on the
98821 command line are implementation-defined.

98822 **Inference Rules**

98823 Inference rules are formatted as follows:

98824 *target*:
98825 <tab>*command*
98826 [<tab>*command*]
98827 ...

98828 *line that does not begin with* <tab> *or* #

98829 The application shall ensure that the *target* portion is a valid target name (see Target Rules, on
98830 page 2974) of the form **.s2** or **.s1.s2** (where **.s1** and **.s2** are suffixes that have been given as
98831 prerequisites of the **.SUFFIXES** special target and *s1* and *s2* do not contain any <slash> or
98832 <period> characters.) If there is only one <period> in the target, it is a single-suffix inference
98833 rule. Targets with two periods are double-suffix inference rules. Inference rules can have only
98834 one target before the <colon>.

The application shall ensure that the makefile does not specify prerequisites for inference rules; no characters other than white space shall follow the <colon> in the first line, except when creating the *empty rule*, described below. Prerequisites are inferred, as described below.

Inference rules can be redefined. A target that matches an existing inference rule shall overwrite the old inference rule. An empty rule can be created with a command consisting of simply a <semicolon> (that is, the rule still exists and is found during inference rule search, but since it is empty, execution has no effect). The empty rule can also be formatted as follows:

```
rule: ;
```

where zero or more <blank> characters separate the <colon> and <semicolon>.

The *make* utility uses the suffixes of targets and their prerequisites to infer how a target can be made up-to-date. A list of inference rules defines the commands to be executed. By default, *make* contains a built-in set of inference rules. Additional rules can be specified in the makefile.

The special target **.SUFFIXES** contains as its prerequisites a list of suffixes that shall be used by the inference rules. The order in which the suffixes are specified defines the order in which the inference rules for the suffixes are used. New suffixes shall be appended to the current list by specifying a **.SUFFIXES** special target in the makefile. A **.SUFFIXES** target with no prerequisites shall clear the list of suffixes. An empty **.SUFFIXES** target followed by a new **.SUFFIXES** list is required to change the order of the suffixes.

Normally, the user would provide an inference rule for each suffix. The inference rule to update a target with a suffix **.s1** from a prerequisite with a suffix **.s2** is specified as a target **.s2.s1**. The internal macros provide the means to specify general inference rules (see Internal Macros, on page 2979).

When no target rule is found to update a target, the inference rules shall be checked. The suffix of the target (**.s1**) to be built is compared to the list of suffixes specified by the **.SUFFIXES** special targets. If the **.s1** suffix is found in **.SUFFIXES**, the inference rules shall be searched in the order defined for the first **.s2.s1** rule whose prerequisite file (**$*.s2**) exists. If the target is out-of-date with respect to this prerequisite, the commands for that inference rule shall be executed.

If the target to be built does not contain a suffix and there is no rule for the target, the single suffix inference rules shall be checked. The single-suffix inference rules define how to build a target if a file is found with a name that matches the target name with one of the single suffixes appended. A rule with one suffix **.s2** is the definition of how to build *target* from **target.s2**. The other suffix (**.s1**) is treated as null.

XSI A <tilde> (`'~'`) in the above rules refers to an SCCS file in the current directory. Thus, the rule **.c~.o** would transform an SCCS C-language source file into an object file (**.o**). Because the **s.** of the SCCS files is a prefix, it is incompatible with *make*'s suffix point of view. Hence, the `'~'` is a way of changing any file reference into an SCCS file reference.

Libraries

If a target or prerequisite contains parentheses, it shall be treated as a member of an archive library. For the *lib*(*member***.o**) expression *lib* refers to the name of the archive library and *member***.o** to the member name. The application shall ensure that the member is an object file with the **.o** suffix. The modification time of the expression is the modification time for the member as kept in the archive library; see *ar*. The **.a** suffix shall refer to an archive library. The **.s2.a** rule shall be used to update a member in the library from a file with a suffix **.s2**.

98878 **Internal Macros**

98879 The *make* utility shall maintain five internal macros that can be used in target and inference rules.
98880 In order to clearly define the meaning of these macros, some clarification of the terms *target rule*,
98881 *inference rule*, *target*, and *prerequisite* is necessary.

98882 Target rules are specified by the user in a makefile for a particular target. Inference rules are
98883 user-specified or *make*-specified rules for a particular class of target name. Explicit prerequisites
98884 are those prerequisites specified in a makefile on target lines. Implicit prerequisites are those
98885 prerequisites that are generated when inference rules are used. Inference rules are applied to
98886 implicit prerequisites or to explicit prerequisites that do not have target rules defined for them in
98887 the makefile. Target rules are applied to targets specified in the makefile.

98888 Before any target in the makefile is updated, each of its prerequisites (both explicit and implicit)
98889 shall be updated. This shall be accomplished by recursively processing each prerequisite. Upon
98890 recursion, each prerequisite shall become a target itself. Its prerequisites in turn shall be
98891 processed recursively until a target is found that has no prerequisites, or further recursion would
98892 require applying two inference rules one immediately after the other, at which point the
98893 recursion shall stop. As an extension, implementations may continue recursion when two or
98894 more successive inference rules need to be applied; however, if there are multiple different
98895 chains of such rules that could be used to create the target, it is unspecified which chain is used.
98896 The recursion shall then back up, updating each target as it goes.

98897 In the definitions that follow, the word *target* refers to one of:

98898 A target specified in the makefile

98899 An explicit prerequisite specified in the makefile that becomes the target when *make*
98900 processes it during recursion

98901 An implicit prerequisite that becomes a target when *make* processes it during recursion

98902 In the definitions that follow, the word *prerequisite* refers to one of the following:

98903 An explicit prerequisite specified in the makefile for a particular target

98904 An implicit prerequisite generated as a result of locating an appropriate inference rule and
98905 corresponding file that matches the suffix of the target

98906 The five internal macros are:

98907 $@ The $@ shall evaluate to the full target name of the current target, or the archive
98908 filename part of a library archive target. It shall be evaluated for both target and
98909 inference rules.

98910 For example, in the **.c.a** inference rule, $@ represents the out-of-date **.a** file to be built.
98911 Similarly, in a makefile target rule to build **lib.a** from **file.c**, $@ represents the out-of-
98912 date **lib.a**.

98913 $% The $% macro shall be evaluated only when the current target is an archive library
98914 member of the form *libname*(*member***.o**). In these cases, $@ shall evaluate to *libname* and
98915 $% shall evaluate to *member***.o**. The $% macro shall be evaluated for both target and
98916 inference rules.

98917 For example, in a makefile target rule to build **lib.a**(**file.o**), $% represents **file.o**, as
98918 opposed to $@, which represents **lib.a**.

98919 $? The $? macro shall evaluate to the list of prerequisites that are newer than the current
98920 target. It shall be evaluated for both target and inference rules.

98921 For example, in a makefile target rule to build *prog* from **file1.o**, **file2.o**, and **file3.o**, and
98922 where *prog* is not out-of-date with respect to **file1.o**, but is out-of-date with respect to
98923 **file2.o** and **file3.o**, $? represents **file2.o** and **file3.o**.

98924 $< In an inference rule, the $< macro shall evaluate to the filename whose existence
98925 allowed the inference rule to be chosen for the target. In the **.DEFAULT** rule, the $<
98926 macro shall evaluate to the current target name. The meaning of the $< macro shall be
98927 otherwise unspecified.

98928 For example, in the **.c.a** inference rule, $< represents the prerequisite **.c** file.

98929 $* The $* macro shall evaluate to the current target name with its suffix deleted. It shall be
98930 evaluated at least for inference rules.

98931 For example, in the **.c.a** inference rule, $*.o represents the out-of-date **.o** file that
98932 corresponds to the prerequisite **.c** file.

98933 Each of the internal macros has an alternative form. When an uppercase `'D'` or `'F'` is appended
98934 to any of the macros, the meaning shall be changed to the *directory part* for `'D'` and *filename part*
98935 for `'F'`. The directory part is the path prefix of the file without a trailing <slash>; for the current
98936 directory, the directory part is `'.'`. When the $? macro contains more than one prerequisite
98937 filename, the $(?D) and $(?F) (or ${?D} and ${?F}) macros expand to a list of directory name parts
98938 and filename parts respectively.

98939 For the target *lib*(*member***.o**) and the **s2.a** rule, the internal macros shall be defined as:

98940 $< *member***.s2**

98941 $* *member*

98942 $@ *lib*

98943 $? *member***.s2**

98944 $% *member***.o**

98945 **Default Rules**

98946 The default rules for *make* shall achieve results that are the same as if the following were used.
98947 Implementations that do not support the C-Language Development Utilities option may omit
98948 **CC**, **CFLAGS**, **YACC**, **YFLAGS**, **LEX**, **LFLAGS**, **LDFLAGS**, and the **.c**, **.y**, and **.l** inference rules.
98949 Implementations that do not support FORTRAN may omit **FC**, **FFLAGS**, and the **.f** inference
98950 rules. Implementations may provide additional macros and rules.

98951 *SPECIAL TARGETS*

98952 XSI
```
.SCCS_GET: sccs $(SCCSFLAGS) get $(SCCSGETFLAGS) $@
```

98953 XSI
```
.SUFFIXES: .o .c .y .l .a .sh .f .c~ .y~ .l~ .sh~ .f~
```

98954 *MACROS*

```
98955 MAKE=make
98956 AR=ar
98957 ARFLAGS=-rv
98958 YACC=yacc
98959 YFLAGS=
98960 LEX=lex
98961 LFLAGS=
```

```
98962           LDFLAGS=
98963           CC=c99
98964           CFLAGS=-O 1
98965           FC=fort77
98966           FFLAGS=-O 1
98967 XSI       GET=get
98968           GFLAGS=
98969           SCCSFLAGS=
98970           SCCSGETFLAGS=-s
```

98971 *SINGLE SUFFIX RULES*

```
98972           .c:
98973               $(CC) $(CFLAGS) $(LDFLAGS) -o $@ $<
98974           .f:
98975               $(FC) $(FFLAGS) $(LDFLAGS) -o $@ $<
98976           .sh:
98977               cp $< $@
98978               chmod a+x $@
98979 XSI       .c~:
98980               $(GET) $(GFLAGS) -p $< > $*.c
98981               $(CC) $(CFLAGS) $(LDFLAGS) -o $@ $*.c
98982           .f~:
98983               $(GET) $(GFLAGS) -p $< > $*.f
98984               $(FC) $(FFLAGS) $(LDFLAGS) -o $@ $*.f
98985           .sh~:
98986               $(GET) $(GFLAGS) -p $< > $*.sh
98987               cp $*.sh $@
98988               chmod a+x $@
```

98989 *DOUBLE SUFFIX RULES*

```
98990           .c.o:
98991               $(CC) $(CFLAGS) -c $<
98992           .f.o:
98993               $(FC) $(FFLAGS) -c $<
98994           .y.o:
98995               $(YACC) $(YFLAGS) $<
98996               $(CC) $(CFLAGS) -c y.tab.c
98997               rm -f y.tab.c
98998               mv y.tab.o $@
98999           .l.o:
99000               $(LEX) $(LFLAGS) $<
99001               $(CC) $(CFLAGS) -c lex.yy.c
99002               rm -f lex.yy.c
99003               mv lex.yy.o $@
99004           .y.c:
```

```
99005               $(YACC) $(YFLAGS) $<
99006               mv y.tab.c $@
99007           .l.c:
99008               $(LEX) $(LFLAGS) $<
99009               mv lex.yy.c $@
99010 XSI     .c~.o:
99011               $(GET) $(GFLAGS) -p $< > $*.c
99012               $(CC) $(CFLAGS) -c $*.c
99013           .f~.o:
99014               $(GET) $(GFLAGS) -p $< > $*.f
99015               $(FC) $(FFLAGS) -c $*.f
99016           .y~.o:
99017               $(GET) $(GFLAGS) -p $< > $*.y
99018               $(YACC) $(YFLAGS) $*.y
99019               $(CC) $(CFLAGS) -c y.tab.c
99020               rm -f y.tab.c
99021               mv y.tab.o $@
99022           .l~.o:
99023               $(GET) $(GFLAGS) -p $< > $*.l
99024               $(LEX) $(LFLAGS) $*.l
99025               $(CC) $(CFLAGS) -c lex.yy.c
99026               rm -f lex.yy.c
99027               mv lex.yy.o $@
99028           .y~.c:
99029               $(GET) $(GFLAGS) -p $< > $*.y
99030               $(YACC) $(YFLAGS) $*.y
99031               mv y.tab.c $@
99032           .l~.c:
99033               $(GET) $(GFLAGS) -p $< > $*.l
99034               $(LEX) $(LFLAGS) $*.l
99035               mv lex.yy.c $@

99036           .c.a:
99037               $(CC) -c $(CFLAGS) $<
99038               $(AR) $(ARFLAGS) $@ $*.o
99039               rm -f $*.o
99040           .f.a:
99041               $(FC) -c $(FFLAGS) $<
99042               $(AR) $(ARFLAGS) $@ $*.o
99043               rm -f $*.o
```

99044 **EXIT STATUS**

99045 When the **-q** option is specified, the *make* utility shall exit with one of the following values:

99046 0 Successful completion.

99047 1 The target was not up-to-date.

>1 An error occurred.

When the **−q** option is not specified, the *make* utility shall exit with one of the following values:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If there is a source file (such as **./source.c**) and there are two SCCS files corresponding to it (**./s.source.c** and **./SCCS/s.source.c**), on XSI-conformant systems *make* uses the SCCS file in the current directory. However, users are advised to use the underlying SCCS utilities (*admin*, *delta*, *get*, and so on) or the *sccs* utility for all source files in a given directory. If both forms are used for a given source file, future developers are very likely to be confused.

It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The **−k** and **−S** options are both present so that the relationship between the command line, the *MAKEFLAGS* variable, and the makefile can be controlled precisely. If the **k** flag is passed in *MAKEFLAGS* and a command is of the form:

```
$(MAKE) −S foo
```

then the default behavior is restored for the child *make*.

When the **−n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* **−n** *target* to be used to see all of the action that would be taken to update *target*.

Because of widespread historical practice, interpreting a <number-sign> (`'#'`) inside a variable as the start of a comment has the unfortunate side-effect of making it impossible to place a <number-sign> in a variable, thus forbidding something like:

```
CFLAGS = "−D COMMENT_CHAR='#'"
```

Many historical *make* utilities stop chaining together inference rules when an intermediate target is nonexistent. For example, it might be possible for a *make* to determine that both **.y.c** and **.c.o** could be used to convert a **.y** to a **.o**. Instead, in this case, *make* requires the use of a **.y.o** rule.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other parts of this volume of POSIX.1-2017. The default rules include rules for optional commands in this volume of POSIX.1-2017. Only rules pertaining to commands that are provided are needed in an implementation's default set.

Macros used within other macros are evaluated when the new macro is used rather than when the new macro is defined. Therefore:

```
MACRO = value1
NEW   = $(MACRO)
MACRO = value2

target:
    echo $(NEW)
```

would produce *value2* and not *value1* since **NEW** was not expanded until it was needed in the *echo* command line.

Some historical applications have been known to intermix *target_name* and *macro=name* operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, although some backwards-compatibility support may be included in some implementations.

The following characters in filenames may give trouble: `'='`, `':'`, `'`'`, single-quote, and `'@'`. In include filenames, pattern matching characters and `'"'` should also be avoided, as they may be treated as special by some implementations.

For inference rules, the description of $< and $? seem similar. However, an example shows the minor difference. In a makefile containing:

```
foo.o: foo.h
```

if **foo.h** is newer than **foo.o**, yet **foo.c** is older than **foo.o**, the built-in rule to make **foo.o** from **foo.c** is used, with $< equal to **foo.c** and $? equal to **foo.h**. If **foo.c** is also newer than **foo.o**, $< is equal to **foo.c** and $? is equal to **foo.h foo.c**.

As a consequence of the general rules for target updating, a useful special case is that if a target has no prerequisites and no commands, and the target of the rule is a nonexistent file, then *make* acts as if this target has been updated whenever its rule is run.

Note: This implies that all targets depending on this one will always have their commands run.

Shell command sequences like `make; cp original copy; make` may have problems on filesystems where the timestamp resolution is the minimum (1 second) required by the standard and where *make* considers identical timestamps to be up-to-date. Conversely, rules like `copy: original; cp -p original copy` will result in redundant work on *make* implementations that consider identical timestamps to be out-of-date.

This standard does not specify precedence between macro definition and include directives. Thus, the behavior of:

```
include =foo.mk
```

is unspecified. To define a variable named include, either the white space before the <equal-sign> should be removed, or another macro should be used, as in:

```
INCLUDE_NAME = include
$(INCLUDE_NAME) =foo.mk
```

On the other hand, if the intent is to include a file which starts with an <equal-sign>, either the filename should be changed to `./=foo.mk`, or the makefile should be written as:

```
INCLUDE_FILE = =foo.mk
include $(INCLUDE_FILE)
```

EXAMPLES

1. The following command:

   ```
   make
   ```

   makes the first target found in the makefile.

2. The following command:

   ```
   make junk
   ```

   makes the target **junk**.

3. The following makefile says that **pgm** depends on two files, **a.o** and **b.o**, and that they in turn depend on their corresponding source files (**a.c** and **b.c**), and a common file **incl.h**:

```
.POSIX:
pgm: a.o b.o
    c99 a.o b.o -o pgm
a.o: incl.h a.c
    c99 -c a.c
b.o: incl.h b.c
    c99 -c b.c
```

4. An example for making optimized **.o** files from **.c** files is:

```
.c.o:
    c99 -c -O 1 $*.c
```

or:

```
.c.o:
    c99 -c -O 1 $<
```

5. The most common use of the archive interface follows. Here, it is assumed that the source files are all C-language source:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
    @echo lib is now up-to-date
```

The **.c.a** rule is used to make **file1.o**, **file2.o**, and **file3.o** and insert them into **lib**.

The treatment of escaped <newline> characters throughout the makefile is historical practice. For example, the inference rule:

```
.c.o\
:
```

works, and the macro:

```
f=  bar baz\
    biz
a:
    echo ==$f==
```

echoes `"==bar baz biz=="`.

If $? were:

```
/usr/include/stdio.h /usr/include/unistd.h foo.h
```

then $(?D) would be:

```
/usr/include /usr/include .
```

and $(?F) would be:

```
stdio.h unistd.h foo.h
```

6. The contents of the built-in rules can be viewed by running:

```
make -p -f /dev/null 2>/dev/null
```

RATIONALE

The *make* utility described in this volume of POSIX.1-2017 is intended to provide the means for changing portable source code into executables that can be run on an POSIX.1-2017-conforming system. It reflects the most common features present in System V and BSD *make*s.

Historically, the *make* utility has been an especially fertile ground for vendor and research organization-specific syntax modifications and extensions. Examples include:

- Syntax supporting parallel execution (such as from various multi-processor vendors, GNU, and others)
- Additional ``operators'' separating targets and their prerequisites (System V, BSD, and others)
- Specifying that command lines containing the strings "`${MAKE}`" and "`$(MAKE)`" are executed when the **−n** option is specified (GNU and System V)
- Modifications of the meaning of internal macros when referencing libraries (BSD and others)
- Using a single instance of the shell for all of the command lines of the target (BSD and others)
- Allowing <space> characters as well as <tab> characters to delimit command lines (BSD)
- Adding C preprocessor-style ``include'' and ``ifdef'' constructs (System V, GNU, BSD, and others)
- Remote execution of command lines (Sprite and others)
- Specifying additional special targets (BSD, System V, and most others)
- Specifying an alternate shell to use to process commands.

Additionally, many vendors and research organizations have rethought the basic concepts of *make*, creating vastly extended, as well as completely new, syntaxes. Each of these versions of *make* fulfills the needs of a different community of users; it is unreasonable for this volume of POSIX.1-2017 to require behavior that would be incompatible (and probably inferior) to historical practice for such a community.

In similar circumstances, when the industry has enough sufficiently incompatible formats as to make them irreconcilable, this volume of POSIX.1-2017 has followed one or both of two courses of action. Commands have been renamed (*cksum*, *echo*, and *pax*) and/or command line options have been provided to select the desired behavior (*grep*, *od*, and *pax*).

Because the syntax specified for the *make* utility is, by and large, a subset of the syntaxes accepted by almost all versions of *make*, it was decided that it would be counter-productive to change the name. And since the makefile itself is a basic unit of portability, it would not be completely effective to reserve a new option letter, such as *make* **−P**, to achieve the portable behavior. Therefore, the special target **.POSIX** was added to the makefile, allowing users to specify ``standard'' behavior. This special target does not preclude extensions in the *make* utility, nor does it preclude such extensions being used by the makefile specifying the target; it does, however, preclude any extensions from being applied that could alter the behavior of previously valid syntax; such extensions must be controlled via command line options or new special targets. It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The portable version of *make* described in this reference page is not intended to be the state-of-the-art software generation tool and, as such, some newer and more leading-edge features have

not been included. An attempt has been made to describe the portable makefile in a manner that does not preclude such extensions as long as they do not disturb the portable behavior described here.

When the −**n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* −**n** *target* to be used to see all of the action that would be taken to update *target*.

The definition of *MAKEFLAGS* allows both the System V letter string and the BSD command line formats. The two formats are sufficiently different to allow implementations to support both without ambiguity.

Early proposals stated that an ``unquoted'' <number-sign> was treated as the start of a comment. The *make* utility does not pay any attention to quotes. A <number-sign> starts a comment regardless of its surroundings.

The text about ``other implementation-defined pathnames may also be tried'' in addition to **./makefile** and **./Makefile** is to allow such extensions as **SCCS/s.Makefile** and other variations. It was made an implementation-defined requirement (as opposed to unspecified behavior) to highlight surprising implementations that might select something unexpected like **/etc/Makefile**. XSI-conformant systems also try **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and **SCCS/s.Makefile**.

Early proposals contained the macro **NPROC** as a means of specifying that *make* should use *n* processes to do the work required. While this feature is a valuable extension for many systems, it is not common usage and could require other non-trivial extensions to makefile syntax. This extension is not required by this volume of POSIX.1-2017, but could be provided as a compatible extension. The macro **PARALLEL** is used by some historical systems with essentially the same meaning (but without using a name that is a common system limit value). It is suggested that implementors recognize the existing use of **NPROC** and/or **PARALLEL** as extensions to *make*.

The default rules are based on System V. The default **CC=** value is *c99* instead of *cc* because this volume of POSIX.1-2017 does not standardize the utility named *cc*. Thus, every conforming application would be required to define **CC=***c99* to expect to run. There is no advantage conferred by the hope that the makefile might hit the ``preferred'' compiler because this cannot be guaranteed to work. Also, since the portable makescript can only use the *c99* options, no advantage is conferred in terms of what the script can do. It is a quality-of-implementation issue as to whether *c99* is as valuable as *cc*.

The −**d** option to *make* is frequently used to produce debugging information, but is too implementation-defined to add to this volume of POSIX.1-2017.

The −**p** option is not passed in *MAKEFLAGS* on most historical implementations and to change this would cause many implementations to break without sufficiently increased portability.

Commands that begin with a <plus-sign> (`'+'`) are executed even if the −**n** option is present. Based on the GNU version of *make*, the behavior of −**n** when the <plus-sign> prefix is encountered has been extended to apply to −**q** and −**t** as well. However, the System V convention of forcing command execution with −**n** when the command line of a target contains either of the strings `"$(MAKE)"` or `"${MAKE}"` has not been adopted. This functionality appeared in early proposals, but the danger of this approach was pointed out with the following example of a portion of a makefile:

```
subdir:
    cd subdir; rm all_the_files; $(MAKE)
```

The loss of the System V behavior in this case is well-balanced by the safety afforded to other makefiles that were not aware of this situation. In any event, the command line <plus-sign>

prefix can provide the desired functionality.

The double <colon> in the target rule format is supported in BSD systems to allow more than one target line containing the same target name to have commands associated with it. Since this is not functionality described in the SVID or XPG3 it has been allowed as an extension, but not mandated.

The default rules are provided with text specifying that the built-in rules shall be the same as if the listed set were used. The intent is that implementations should be able to use the rules without change, but will be allowed to alter them in ways that do not affect the primary behavior.

One point of discussion was whether to drop the default rules list from this volume of POSIX.1-2017. They provide convenience, but do not enhance portability of applications. The prime benefit is in portability of users who wish to type *make command* and have the command build from a **command.c** file.

The historical *MAKESHELL* feature, and related features provided by other *make* implementations, were omitted. In some implementations it is used to let a user override the shell to be used to run *make* commands. This was confusing; for a portable *make*, the shell should be chosen by the makefile writer. Further, a makefile writer cannot require an alternate shell to be used and still consider the makefile portable. While it would be possible to standardize a mechanism for specifying an alternate shell, existing implementations do not agree on such a mechanism, and makefile writers can already invoke an alternate shell by specifying the shell name in the rule for a target; for example:

```
python -c "foo"
```

The *make* utilities in most historical implementations process the prerequisites of a target in left-to-right order, and the makefile format requires this. It supports the standard idiom used in many makefiles that produce *yacc* programs; for example:

```
foo: y.tab.o lex.o main.o
    $(CC) $(CFLAGS) -o $@ t.tab.o lex.o main.o
```

In this example, if *make* chose any arbitrary order, the **lex.o** might not be made with the correct **y.tab.h**. Although there may be better ways to express this relationship, it is widely used historically. Implementations that desire to update prerequisites in parallel should require an explicit extension to *make* or the makefile format to accomplish it, as described previously.

The algorithm for determining a new entry for target rules is partially unspecified. Some historical *make*s allow comment lines (including blank and empty lines) within the collection of commands marked by leading <tab> characters. A conforming makefile must ensure that each command starts with a <tab>, but implementations are free to ignore comments without triggering the start of a new entry.

The ASYNCHRONOUS EVENTS section includes having SIGTERM and SIGHUP, along with the more traditional SIGINT and SIGQUIT, remove the current target unless directed not to do so. SIGTERM and SIGHUP were added to parallel other utilities that have historically cleaned up their work as a result of these signals. When *make* receives any signal other than SIGQUIT, it is required to resend itself the signal it received so that it exits with a status that reflects the signal. The results from SIGQUIT are partially unspecified because, on systems that create **core** files upon receipt of SIGQUIT, the **core** from *make* would conflict with a **core** file from the command that was running when the SIGQUIT arrived. The main concern was to prevent damaged files from appearing up-to-date when *make* is rerun.

The **.PRECIOUS** special target was extended to affect all targets globally (by specifying no

prerequisites). The **.IGNORE** and **.SILENT** special targets were extended to allow prerequisites; it was judged to be more useful in some cases to be able to turn off errors or echoing for a list of targets than for the entire makefile. These extensions to *make* in System V were made to match historical practice from the BSD *make*.

Macros are not exported to the environment of commands to be run. This was never the case in any historical *make* and would have serious consequences. The environment is the same as the environment to *make* except that *MAKEFLAGS* and macros defined on the *make* command line are added, and except that macros defined by the *MAKEFLAGS* environment variable and macros defined in the makefile(s) may update the value of an existing environment variable (other than *SHELL*).

Some implementations do not use *system*() for all command lines, as required by the portable makefile format; as a performance enhancement, they select lines without shell metacharacters for direct execution by *execve*(). There is no requirement that *system*() be used specifically, but merely that the same results be achieved. The metacharacters typically used to bypass the direct *execve*() execution have been any of:

```
=  |  ^  (  )  ;  &  <  >  *  ?  [  ]  :  $  `  '  "  \  \n
```

The default in some advanced versions of *make* is to group all the command lines for a target and execute them using a single shell invocation; the System V method is to pass each line individually to a separate shell. The single-shell method has the advantages in performance and the lack of a requirement for many continued lines. However, converting to this newer method has caused portability problems with many historical makefiles, so the behavior with the POSIX makefile is specified to be the same as that of System V. It is suggested that the special target **.ONESHELL** be used as an implementation extension to achieve the single-shell grouping for a target or group of targets.

Novice users of *make* have had difficulty with the historical need to start commands with a <tab>. Since it is often difficult to discern differences between <tab> and <space> characters on terminals or printed listings, confusing bugs can arise. In early proposals, an attempt was made to correct this problem by allowing leading <blank> characters instead of <tab> characters. However, implementors reported many makefiles that failed in subtle ways following this change, and it is difficult to implement a *make* that unambiguously can differentiate between macro and command lines. There is extensive historical practice of allowing leading <space> characters before macro definitions. Forcing macro lines into column 1 would be a significant backwards-compatibility problem for some makefiles. Therefore, historical practice was restored.

There is substantial variation in the handling of include lines by different implementations. However, there is enough commonality for the standard to be able to specify a minimum set of requirements that allow the feature to be used portably. Known variations have been explicitly called out as unspecified behavior in the description.

The System V dynamic dependency feature was not included. It would support:

```
cat: $$@.c
```

that would expand to;

```
cat: cat.c
```

This feature exists only in the new version of System V *make* and, while useful, is not in wide usage. This means that macros are expanded twice for prerequisites: once at makefile parse time and once at target update time.

Consideration was given to adding metarules to the POSIX *make*. This would make **%.o: %.c** the

99350 same as **.c.o:**. This is quite useful and available from some vendors, but it would cause too many
99351 changes to this *make* to support. It would have introduced rule chaining and new substitution
99352 rules. However, the rules for target names have been set to reserve the '%' and '"' characters.
99353 These are traditionally used to implement metarules and quoting of target names, respectively.
99354 Implementors are strongly encouraged to use these characters only for these purposes.

99355 A request was made to extend the suffix delimiter character from a <period> to any character.
99356 The metarules feature in newer *make*s solves this problem in a more general way. This volume of
99357 POSIX.1-2017 is staying with the more conservative historical definition.

99358 The standard output format for the −**p** option is not described because it is primarily a
99359 debugging option and because the format is not generally useful to programs. In historical
99360 implementations the output is not suitable for use in generating makefiles. The −**p** format has
99361 been variable across historical implementations. Therefore, the definition of −**p** was only to
99362 provide a consistently named option for obtaining *make* script debugging information.

99363 Some historical implementations have not cleared the suffix list with −**r**.

99364 Implementations should be aware that some historical applications have intermixed *target_name*
99365 and *macro=value* operands on the command line, expecting that all of the macros are processed
99366 before any of the targets are dealt with. Conforming applications do not do this, but some
99367 backwards-compatibility support may be warranted.

99368 Empty inference rules are specified with a <semicolon> command rather than omitting all
99369 commands, as described in an early proposal. The latter case has no traditional meaning and is
99370 reserved for implementation extensions, such as in GNU *make*.

99371 Earlier versions of this standard defined comment lines only as lines with '#' as the first
99372 character. Many places then talked about comments, blank lines, and empty lines; but some
99373 places inadvertently only mentioned comments when blank lines and empty lines had also been
99374 accepted in all known implementations. The standard now defines comment lines to be blank
99375 lines, empty lines, and lines starting with a '#' character and explictily lists cases where blank
99376 lines and empty lines are not acceptable.

99377 On most historic systems, the *make* utility considered a target with a prerequisite that had an
99378 identical timestamp as up-to-date. The HP-UX implementation of *make* treated it as out-of-date.
99379 The standard now allows either behavior, but implementations are encouraged to follow the
99380 example set by HP-UX. This is especially important on file systems where the timestamp
99381 resolution is the minimum (1 second) required by the standard. All implementations of *make*
99382 should make full use of the finest timestamp resolution available on the file systems holding
99383 targets and prerequisites to ensure that targets are up-to-date even for prerequisite files with
99384 timestamps that were updated within the same second. However, if the timestamp resolutions of
99385 the file systems containing a target and a prerequisite are different, the timestamp with the more
99386 precise resolution should be rounded down to the resolution of the less precise timestamp for
99387 the comparison.

99388 **FUTURE DIRECTIONS**

99389 Some implementations of *make* include an *export* directive to add specified *make* variables to the
99390 environment. This may be considered for standardization in a future version.

99391 A future version of this standard may require that macro expansions using the forms
99392 $(*string1*:[*op*]%[*os*]=[*np*][%][*ns*]) or ${*string1*:[*op*]%[*os*]=[*np*][%][*ns*]} are treated as pattern macro
99393 expansions.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the Software Development Utilities option.

The Open Group Corrigendum U029/1 is applied, correcting a typographical error in the SPECIAL TARGETS section.

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from ``otherwise, the home directory of a user of that name is examined'' to ``otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory is examined''.

It is specified whether the command line is related to the makefile or to the *make* command, and the macro processing rules are updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

PASC Interpretation 1003.2 #193 is applied.

Issue 7

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Include lines in makefiles are introduced.

Austin Group Interpretation 1003.1-2001 #131 is applied, changing the **Makefile Execution** section.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0121 [257] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0122 [509], XCU/TC2-2008/0123 [584], XCU/TC2-2008/0124 [857], XCU/TC2-2008/0125 [505], XCU/TC2-2008/0126 [584], XCU/TC2-2008/0127 [505], XCU/TC2-2008/0128 [865], XCU/TC2-2008/0129 [693], XCU/TC2-2008/0130 [602], XCU/TC2-2008/0131 [848], XCU/TC2-2008/0132 [763], XCU/TC2-2008/0133 [857], XCU/TC2-2008/0134 [866], XCU/TC2-2008/0135 [525], XCU/TC2-2008/0136 [848], XCU/TC2-2008/0137 [769], XCU/TC2-2008/0138 [525], XCU/TC2-2008/0139 [769], XCU/TC2-2008/0140 [505], XCU/TC2-2008/0141 [693], XCU/TC2-2008/0142 [505], XCU/TC2-2008/0143 [857], and XCU/TC2-2008/0144 [693,865] are applied.

NAME

man ‡'display system documentation

SYNOPSIS

```
man [−k] name...
```

DESCRIPTION

The *man* utility shall write information about each of the *name* operands. If *name* is the name of a standard utility, *man* at a minimum shall write a message describing the syntax used by the standard utility, its options, and operands. If more information is available, the *man* utility shall provide it in an implementation-defined manner.

An implementation may provide information for values of *name* other than the standard utilities. Standard utilities that are listed as optional and that are not supported by the implementation either shall cause a brief message indicating that fact to be displayed or shall cause a full display of information as described previously.

OPTIONS

The *man* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−k Interpret *name* operands as keywords to be used in searching a utilities summary database that contains a brief purpose entry for each standard utility and write lines from the summary database that match any of the keywords. The keyword search shall produce results that are the equivalent of the output of the following command:

```
grep −Ei '
name
name
...
' summary-database
```

This assumes that the *summary-database* is a text file with a single entry per line; this organization is not required and the example using *grep* **−Ei** is merely illustrative of the type of search intended. The purpose entry to be included in the database shall consist of a terse description of the purpose of the utility.

OPERANDS

The following operand shall be supported:

name A keyword or the name of a standard utility. When **−k** is not specified and *name* does not represent one of the standard utilities, the results are unspecified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *man*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

99474 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
99475 characters (for example, single-byte as opposed to multi-byte characters in
99476 arguments and in the summary database). The value of *LC_CTYPE* need not affect
99477 the format of the information written about the *name* operands.

99478 *LC_MESSAGES*
99479 Determine the locale that should be used to affect the format and contents of
99480 diagnostic messages written to standard error and informative messages written to
99481 standard output.

99482 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

99483 *PAGER* Determine an output filtering command for writing the output to a terminal. Any
99484 string acceptable as a *command_string* operand to the *sh* **−c** command shall be valid.
99485 When standard output is a terminal device, the reference page output shall be
99486 piped through the command. If the *PAGER* variable is null or not set, the command
99487 shall be either *more* or another paginator utility documented in the system
99488 documentation.

99489 **ASYNCHRONOUS EVENTS**
99490 Default.

99491 **STDOUT**
99492 The *man* utility shall write text describing the syntax of the utility *name*, its options and its
99493 operands, or, when **−k** is specified, lines from the summary database. The format of this text is
99494 implementation-defined.

99495 **STDERR**
99496 The standard error shall be used for diagnostic messages, and may also be used for
99497 informational messages of unspecified format.

99498 **OUTPUT FILES**
99499 None.

99500 **EXTENDED DESCRIPTION**
99501 None.

99502 **EXIT STATUS**
99503 The following exit values shall be returned:

99504 0 Successful completion.

99505 >0 An error occurred.

99506 **CONSEQUENCES OF ERRORS**
99507 Default.

99508 **APPLICATION USAGE**
99509 None.

99510 **EXAMPLES**
99511 None.

99512 **RATIONALE**
99513 It is recognized that the *man* utility is only of minimal usefulness as specified. The opinion of the
99514 standard developers was strongly divided as to how much or how little information *man* should
99515 be required to provide. They considered, however, that the provision of some portable way of
99516 accessing documentation would aid user portability. The arguments against a fuller specification
99517 were:

Large quantities of documentation should not be required on a system that does not have excess disk space.

The current manual system does not present information in a manner that greatly aids user portability.

A ``better help system'' is currently an area in which vendors feel that they can add value to their POSIX implementations.

The **–f** option was considered, but due to implementation differences, it was not included in this volume of POSIX.1-2017.

The description was changed to be more specific about what has to be displayed for a utility. The standard developers considered it insufficient to allow a display of only the synopsis without giving a short description of what each option and operand does.

The ``purpose'' entry to be included in the database can be similar to the section title (less the numeric prefix) from this volume of POSIX.1-2017 for each utility. These titles are similar to those used in historical systems for this purpose.

See *mailx* for rationale concerning the default paginator.

The caveat in the *LC_CTYPE* description was added because it is not a requirement that an implementation provide reference pages for all of its supported locales on each system; changing *LC_CTYPE* does not necessarily translate the reference page into another language. This is equivalent to the current state of *LC_MESSAGES* in POSIX.1-2017 ‡locale-specific messages are not yet a requirement.

The historical *MANPATH* variable is not included in POSIX because no attempt is made to specify naming conventions for reference page files, nor even to mandate that they are files at all. On some implementations they could be a true database, a hypertext file, or even fixed strings within the *man* executable. The standard developers considered the portability of reference pages to be outside their scope of work. However, users should be aware that *MANPATH* is implemented on a number of historical systems and that it can be used to tailor the search pattern for reference pages from the various categories (utilities, functions, file formats, and so on) when the system administrator reveals the location and conventions for reference pages on the system.

The keyword search can rely on at least the text of the section titles from these utility descriptions, and the implementation may add more keywords. The term ``section titles'' refers to the strings such as:

```
man — Display system documentation
ps — Report process status
```

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 7

Austin Group Interpretation 1003.1-2001 #108 is applied, clarifying that informational messages may appear on standard error.

99564 **NAME**

99565 mesg ‡'permit or deny messages

99566 **SYNOPSIS**

99567 `mesg [y|n]`

99568 **DESCRIPTION**

99569 The *mesg* utility shall control whether other users are allowed to send messages via *write*, *talk*, or
99570 other utilities to a terminal device. The terminal device affected shall be determined by searching
99571 for the first terminal in the sequence of devices associated with standard input, standard output,
99572 and standard error, respectively. With no arguments, *mesg* shall report the current state without
99573 changing it. Processes with appropriate privileges may be able to send messages to the terminal
99574 independent of the current state.

99575 **OPTIONS**

99576 None.

99577 **OPERANDS**

99578 The following operands shall be supported in the POSIX locale:

99579 *y* Grant permission to other users to send messages to the terminal device.

99580 *n* Deny permission to other users to send messages to the terminal device.

99581 **STDIN**

99582 Not used.

99583 **INPUT FILES**

99584 None.

99585 **ENVIRONMENT VARIABLES**

99586 The following environment variables shall affect the execution of *mesg*:

99587 *LANG* Provide a default value for the internationalization variables that are unset or null.
99588 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
99589 variables used to determine the values of locale categories.)

99590 *LC_ALL* If set to a non-empty string value, override the values of all the other
99591 internationalization variables.

99592 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
99593 characters (for example, single-byte as opposed to multi-byte characters in
99594 arguments).

99595 *LC_MESSAGES*
99596 Determine the locale that should be used to affect the format and contents of
99597 diagnostic messages written (by *mesg*) to standard error.

99598 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

99599 **ASYNCHRONOUS EVENTS**

99600 Default.

99601 **STDOUT**

99602 If no operand is specified, *mesg* shall display the current terminal state in an unspecified format.

99603 **STDERR**

99604 The standard error shall be used only for diagnostic messages.

99605 **OUTPUT FILES**

99606 None.

99607 **EXTENDED DESCRIPTION**

99608 None.

99609 **EXIT STATUS**

99610 The following exit values shall be returned:

99611 0 Receiving messages is allowed.

99612 1 Receiving messages is not allowed.

99613 >1 An error occurred.

99614 **CONSEQUENCES OF ERRORS**

99615 Default.

99616 **APPLICATION USAGE**

99617 The mechanism by which the message status of the terminal is changed is unspecified.
99618 Therefore, unspecified actions may cause the status of the terminal to change after *mesg* has
99619 successfully completed. These actions may include, but are not limited to: another invocation of
99620 the *mesg* utility, login procedures; invocation of the *stty* utility, invocation of the *chmod* utility or
99621 *chmod*( ) function, and so on.

99622 **EXAMPLES**

99623 None.

99624 **RATIONALE**

99625 The terminal changed by *mesg* is that associated with the standard input, output, or error, rather
99626 than the controlling terminal for the session. This is because users logged in more than once
99627 should be able to change any of their login terminals without having to stop the job running in
99628 those sessions. This is not a security problem involving the terminals of other users because
99629 appropriate privileges would be required to affect the terminal of another user.

99630 The method of checking each of the first three file descriptors in sequence until a terminal is
99631 found was adopted from System V.

99632 The file **/dev/tty** is not specified for the terminal device because it was thought to be too
99633 restrictive. Typical environment changes for the *n* operand are that write permissions are
99634 removed for *others* and *group* from the appropriate device. It was decided to leave the actual
99635 description of what is done as unspecified because of potential differences between
99636 implementations.

99637 The format for standard output is unspecified because of differences between historical
99638 implementations. This output is generally not useful to shell scripts (they can use the exit status),
99639 so exact parsing of the output is unnecessary.

99640 **FUTURE DIRECTIONS**

99641 None.

99645 **CHANGE HISTORY**

99646 First released in Issue 2.

99647 **Issue 6**

99648 This utility is marked as part of the User Portability Utilities option.

99649 **Issue 7**

99650 The *mesg* utility is moved from the User Portability Utilities option to the Base. User Portability
99651 Utilities is now an option for interactive utilities.

NAME

mkdir — make directories

SYNOPSIS

```
mkdir [−p] [−m mode] dir...
```

DESCRIPTION

The *mkdir* utility shall create the directories specified by the operands, in the order specified.

For each *dir* operand, the *mkdir* utility shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of POSIX.1-2017, called with the following arguments:

1. The *dir* operand is used as the *path* argument.
2. The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO is used as the *mode* argument. (If the **−m** option is specified, the value of the *mkdir*( ) *mode* argument is unspecified, but the directory shall at no time have permissions less restrictive than the **−m** *mode* option-argument.)

OPTIONS

The *mkdir* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−m *mode* Set the file permission bits of the newly-created directory to the specified *mode* value. The *mode* option-argument shall be the same as the *mode* operand defined for the *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'−'` shall be interpreted relative to an assumed initial mode of *a=rwx*; `'+'` shall add permissions to the default mode, `'−'` shall delete permissions from the default mode.

−p Create any missing intermediate pathname components.

For each *dir* operand that does not name an existing directory, before performing the actions described in the DESCRIPTION above, the *mkdir* utility shall create any pathname components of the path prefix of *dir* that do not name an existing directory by performing actions equivalent to first calling the *mkdir*( ) function with the following arguments:

1. A pathname naming the missing pathname component, ending with a trailing <slash> character, as the *path* argument
2. The value zero as the *mode* argument

and then calling the *chmod*( ) function with the following arguments:

1. The same *path* argument as in the *mkdir*( ) call
2. The value `(S_IWUSR|S_IXUSR|~`*filemask*`)&0777` as the *mode* argument, where *filemask* is the file mode creation mask of the process (see XSH *umask*( ))

Each *dir* operand that names an existing directory shall be ignored without error.

OPERANDS

The following operand shall be supported:

dir A pathname of a directory to be created.

99692 **STDIN**

99693 Not used.

99694 **INPUT FILES**

99695 None.

99696 **ENVIRONMENT VARIABLES**

99697 The following environment variables shall affect the execution of *mkdir*:

99698 *LANG* Provide a default value for the internationalization variables that are unset or null.
99699 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
99700 variables used to determine the values of locale categories.)

99701 *LC_ALL* If set to a non-empty string value, override the values of all the other
99702 internationalization variables.

99703 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
99704 characters (for example, single-byte as opposed to multi-byte characters in
99705 arguments).

99706 *LC_MESSAGES*
99707 Determine the locale that should be used to affect the format and contents of
99708 diagnostic messages written to standard error.

99709 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

99710 **ASYNCHRONOUS EVENTS**

99711 Default.

99712 **STDOUT**

99713 Not used.

99714 **STDERR**

99715 The standard error shall be used only for diagnostic messages.

99716 **OUTPUT FILES**

99717 None.

99718 **EXTENDED DESCRIPTION**

99719 None.

99720 **EXIT STATUS**

99721 The following exit values shall be returned:

99722 0 All the specified directories were created successfully, or the **−p** option was specified and all
99723 the specified directories either already existed or were created successfully.

99724 >0 An error occurred.

99725 **CONSEQUENCES OF ERRORS**

99726 Default.

APPLICATION USAGE

The default file mode for directories is *a=rwx* (777 on most systems) with selected permissions removed in accordance with the file mode creation mask. For intermediate pathname components created by *mkdir*, the mode is the default modified by *u+wx* so that the subdirectories can always be created regardless of the file mode creation mask; if different ultimate permissions are desired for the intermediate directories, they can be changed afterwards with *chmod*.

Note that some of the requested directories may have been created even if an error occurs.

EXAMPLES

None.

RATIONALE

The System V **−m** option was included to control the file mode.

The System V **−p** option was included to create any needed intermediate directories and to complement the functionality provided by *rmdir* for removing directories in the path prefix as they become empty. Because no error is produced if any path component already exists, the **−p** option is also useful to ensure that a particular directory exists.

The functionality of *mkdir* is described substantially through a reference to the *mkdir*( ) function in the System Interfaces volume of POSIX.1-2017. For example, by default, the mode of the directory is affected by the file mode creation mask in accordance with the specified behavior of the *mkdir*( ) function. In this way, there is less duplication of effort required for describing details of the directory creation.

FUTURE DIRECTIONS

None.

SD5-XCU-ERN-56 is applied, aligning the **−m** option with the IEEE P1003.2b draft standard to clarify an ambiguity.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0122 [161] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0145 [843] is applied.

99764 **NAME**

99765 mkfifo ‡'make FIFO special files

99766 **SYNOPSIS**

99767 `mkfifo [-m mode] file...`

99768 **DESCRIPTION**

99769 The *mkfifo* utility shall create the FIFO special files specified by the operands, in the order
99770 specified.

99771 For each *file* operand, the *mkfifo* utility shall perform actions equivalent to the *mkfifo*() function
99772 defined in the System Interfaces volume of POSIX.1-2017, called with the following arguments:

99773 1. The *file* operand is used as the *path* argument.

99774 2. The value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP,
99775 S_IROTH, and S_IWOTH is used as the *mode* argument. (If the **-m** option is specified, the
99776 value of the *mkfifo*() *mode* argument is unspecified, but the FIFO shall at no time have
99777 permissions less restrictive than the **-m** *mode* option-argument.)

99778 **OPTIONS**

99779 The *mkfifo* utility shall conform to XBD Section 12.2 (on page 216).

99780 The following option shall be supported:

99781 **-m** *mode* Set the file permission bits of the newly-created FIFO to the specified *mode* value.
99782 The *mode* option-argument shall be the same as the *mode* operand defined for the
99783 *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'-'` shall be
99784 interpreted relative to an assumed initial mode of *a=rw*.

99785 **OPERANDS**

99786 The following operand shall be supported:

99787 *file* A pathname of the FIFO special file to be created.

99788 **STDIN**

99789 Not used.

99790 **INPUT FILES**

99791 None.

99792 **ENVIRONMENT VARIABLES**

99793 The following environment variables shall affect the execution of *mkfifo*:

99794 *LANG* Provide a default value for the internationalization variables that are unset or null.
99795 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
99796 variables used to determine the values of locale categories.)

99797 *LC_ALL* If set to a non-empty string value, override the values of all the other
99798 internationalization variables.

99799 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
99800 characters (for example, single-byte as opposed to multi-byte characters in
99801 arguments).

99802 *LC_MESSAGES*
99803 Determine the locale that should be used to affect the format and contents of
99804 diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All the specified FIFO special files were created successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

This utility was added to permit shell applications to create FIFO special files.

The **−m** option was added to control the file mode, for consistency with the similar functionality provided by the *mkdir* utility.

Early proposals included a **−p** option similar to the *mkdir* **−p** option that created intermediate directories leading up to the FIFO specified by the final component. This was removed because it is not commonly needed and is not common practice with similar utilities.

The functionality of *mkfifo* is described substantially through a reference to the *mkfifo*( ) function in the System Interfaces volume of POSIX.1-2017. For example, by default, the mode of the FIFO file is affected by the file mode creation mask in accordance with the specified behavior of the *mkfifo*( ) function. In this way, there is less duplication of effort required for describing details of the file creation.

FUTURE DIRECTIONS

None.

99844 **CHANGE HISTORY**

99845 First released in Issue 3.

99846 **Issue 6**

99847 The **−m** option is aligned with the IEEE P1003.2b draft standard to clarify an ambiguity.

NAME

more ‡ display files on a page-by-page basis

SYNOPSIS

UP

```
more [−ceisu] [−n number] [−p command] [−t tagstring] [file...]
```

DESCRIPTION

The *more* utility shall read files and either write them to the terminal on a page-by-page basis or filter them to standard output. If standard output is not a terminal device, all input files shall be copied to standard output in their entirety, without modification, except as specified for the **−s** option. If standard output is a terminal device, the files shall be written a number of lines (one screenful) at a time under the control of user commands. See the EXTENDED DESCRIPTION section.

Certain block-mode terminals do not have all the capabilities necessary to support the complete *more* definition; they are incapable of accepting commands that are not terminated with a <newline>. Implementations that support such terminals shall provide an operating mode to *more* in which all commands can be terminated with a <newline> on those terminals. This mode:

Shall be documented in the system documentation

Shall, at invocation, inform the user of the terminal deficiency that requires the <newline> usage and provide instructions on how this warning can be suppressed in future invocations

Shall not be required for implementations supporting only fully capable terminals

Shall not affect commands already requiring <newline> characters

Shall not affect users on the capable terminals from using *more* as described in this volume of POSIX.1-2017

OPTIONS

The *more* utility shall conform to XBD Section 12.2 (on page 216), except that `'+'` may be recognized as an option delimiter as well as `'−'`.

The following options shall be supported:

−c If a screen is to be written that has no lines in common with the current screen, or *more* is writing its first screen, *more* shall not scroll the screen, but instead shall redraw each line of the screen in turn, from the top of the screen to the bottom. In addition, if *more* is writing its first screen, the screen shall be cleared. This option may be silently ignored on devices with insufficient terminal capabilities.

−e Exit immediately after writing the last line of the last file in the argument list; see the EXTENDED DESCRIPTION section.

−i Perform pattern matching in searches without regard to case; see XBD Section 9.2 (on page 182).

−n *number* Specify the number of lines per screenful. The *number* argument is a positive decimal integer. The **−n** option shall override any values obtained from any other source.

−p *command* Each time a screen from a new file is displayed or redisplayed (including as a result of *more* commands; for example, **:p**), execute the *more* command(s) in the command arguments in the order specified, as if entered by the user after the first screen has been displayed. No intermediate results shall be displayed (that is, if the command is a movement to a screen different from the normal first screen, only the

99892 screen resulting from the command shall be displayed.) If any of the commands
99893 fail for any reason, an informational message to this effect shall be written, and no
99894 further commands specified using the −**p** option shall be executed for this file.

99895 −**s** Behave as if consecutive empty lines were a single empty line.

99896 −**t** *tagstring* Write the screenful of the file containing the tag named by the *tagstring* argument.
99897 See the *ctags* utility. The tags feature represented by −**t** *tagstring* and the **:t**
99898 command is optional. It shall be provided on any system that also provides a
99899 conforming implementation of *ctags*; otherwise, the use of −**t** produces undefined
99900 results.

99901 The filename resulting from the −**t** option shall be logically added as a prefix to the
99902 list of command line files, as if specified by the user. If the tag named by the
99903 *tagstring* argument is not found, it shall be an error, and *more* shall take no further
99904 action.

99905 If the tag specifies a line number, the first line of the display shall contain the
99906 beginning of that line. If the tag specifies a pattern, the first line of the display shall
99907 contain the beginning of the matching text from the first line of the file that
99908 contains that pattern. If the line does not exist in the file or matching text is not
99909 found, an informational message to this effect shall be displayed, and *more* shall
99910 display the default screen as if −**t** had not been specified.

99911 If both the −**t** *tagstring* and −**p** *command* options are given, the −**t** *tagstring* shall be
99912 processed first; that is, the file and starting line for the display shall be as specified
99913 by −**t**, and then the −**p** *more* command shall be executed. If the line (matching text)
99914 specified by the −**t** command does not exist (is not found), no −**p** *more* command
99915 shall be executed for this file at any time.

99916 −**u** Treat a <backspace> as a printable control character, displayed as an
99917 implementation-defined character sequence (see the EXTENDED DESCRIPTION
99918 section), suppressing backspacing and the special handling that produces
99919 underlined or standout mode text on some terminal types. Also, do not ignore a
99920 <carriage-return> at the end of a line.

99921 **OPERANDS**

99922 The following operand shall be supported:

99923 *file* A pathname of an input file. If no *file* operands are specified, the standard input
99924 shall be used. If a *file* is `'−'`, the standard input shall be read at that point in the
99925 sequence.

99926 **STDIN**

99927 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.

99928 **INPUT FILES**

99929 The input files being examined shall be text files. If standard output is a terminal, standard error
99930 shall be used to read commands from the user. If standard output is a terminal, standard error is
99931 not readable, and command input is needed, *more* may attempt to obtain user commands from
99932 the controlling terminal (for example, **/dev/tty**); otherwise, *more* shall terminate with an error
99933 indicating that it was unable to read user commands. If standard output is not a terminal, no
99934 error shall result if standard error cannot be opened for reading.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *more*:

COLUMNS Override the system-selected horizontal display line size. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null.

EDITOR Used by the **v** command to select an editor. See the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null. The **−n** option shall take precedence over the *LINES* variable for determining the number of lines in a screenful.

MORE Determine a string containing options described in the OPTIONS section preceded with <hyphen-minus> characters and <blank>-separated as on the command line. Any command line options shall be processed after those in the *MORE* variable, as if the command line were:

```
more $MORE options operands
```

The *MORE* variable shall take precedence over the *TERM* and *LINES* variables for determining the number of lines in a screenful.

TERM Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used to write the contents of the input files.

99975 **STDERR**

99976 The standard error shall be used for diagnostic messages and user commands (see the INPUT
99977 FILES section), and, if standard output is a terminal device, to write a prompting string. The
99978 prompting string shall appear on the screen line below the last line of the file displayed in the
99979 current screenful. The prompt shall contain the name of the file currently being examined and
99980 shall contain an end-of-file indication and the name of the next file, if any, when prompting at
99981 the end-of-file. If an error or informational message is displayed, it is unspecified whether it is
99982 contained in the prompt. If it is not contained in the prompt, it shall be displayed and then the
99983 user shall be prompted for a continuation character, at which point another message or the user
99984 prompt may be displayed. The prompt is otherwise unspecified. It is unspecified whether
99985 informational messages are written for other user commands.

99986 **OUTPUT FILES**

99987 None.

99988 **EXTENDED DESCRIPTION**

99989 The following section describes the behavior of *more* when the standard output is a terminal
99990 device. If the standard output is not a terminal device, no options other than **−s** shall have any
99991 effect, and all input files shall be copied to standard output otherwise unmodified, at which time
99992 *more* shall exit without further action.

99993 The number of lines available per screen shall be determined by the **−n** option, if present, or by
99994 examining values in the environment (see the ENVIRONMENT VARIABLES section). If neither
99995 method yields a number, an unspecified number of lines shall be used.

99996 The maximum number of lines written shall be one less than this number, because the screen
99997 line after the last line written shall be used to write a user prompt and user input. If the number
99998 of lines in the screen is less than two, the results are undefined. It is unspecified whether user
99999 input is permitted to be longer than the remainder of the single line where the prompt has been
100000 written.

100001 The number of columns available per line shall be determined by examining values in the
100002 environment (see the ENVIRONMENT VARIABLES section), with a default value as described
100003 in XBD Chapter 8 (on page 173).

100004 Lines that are longer than the display shall be folded; the length at which folding occurs is
100005 unspecified, but should be appropriate for the output device. Folding may occur between glyphs
100006 of single characters that take up multiple display columns.

100007 When standard output is a terminal and **−u** is not specified, *more* shall treat <backspace> and
100008 <carriage-return> characters specially:

100009 A character, followed first by a sequence of *n* <backspace> characters (where *n* is the same
100010 as the number of column positions that the character occupies), then by *n* <underscore>
100011 characters (`'_'`), shall cause that character to be written as underlined text, if the terminal
100012 type supports that. The *n* <underscore> characters, followed first by *n* <backspace>
100013 characters, then any character with *n* column positions, shall also cause that character to be
100014 written as underlined text, if the terminal type supports that.

100015 A sequence of *n* <backspace> characters (where *n* is the same as the number of column
100016 positions that the previous character occupies) that appears between two identical
100017 printable characters shall cause the first of those two characters to be written as
100018 emboldened text (that is, visually brighter, standout mode, or inverse-video mode), if the
100019 terminal type supports that, and the second to be discarded. Immediately subsequent
100020 occurrences of <backspace>/character pairs for that same character shall also be
100021 discarded. (For example, the sequence `"a\ba\ba\ba"` is interpreted as a single

100022 emboldened `'a'`.)

100023 The *more* utility shall logically discard all other <backspace> characters from the line as
100024 well as the character which precedes them, if any.

100025 A <carriage-return> at the end of a line shall be ignored, rather than being written as a
100026 non-printable character, as described in the next paragraph.

100027 It is implementation-defined how other non-printable characters are written. Implementations
100028 should use the same format that they use for the *ex* **print** command; see the OPTIONS section
100029 within the *ed* utility. It is unspecified whether a multi-column character shall be separated if it
100030 crosses a display line boundary; it shall not be discarded. The behavior is unspecified if the
100031 number of columns on the display is less than the number of columns any single character in the
100032 line being displayed would occupy.

100033 When each new file is displayed (or redisplayed), *more* shall write the first screen of the file.
100034 Once the initial screen has been written, *more* shall prompt for a user command. If the execution
100035 of the user command results in a screen that has lines in common with the current screen, and
100036 the device has sufficient terminal capabilities, *more* shall scroll the screen; otherwise, it is
100037 unspecified whether the screen is scrolled or redrawn.

100038 For all files but the last (including standard input if no file was specified, and for the last file as
100039 well, if the **−e** option was not specified), when *more* has written the last line in the file, *more* shall
100040 prompt for a user command. This prompt shall contain the name of the next file as well as an
100041 indication that *more* has reached end-of-file. If the user command is **f**, <control>-F, <space>, **j**,
100042 <newline>, **d**, <control>-D, or **s**, *more* shall display the next file. Otherwise, if displaying the last
100043 file, *more* shall exit. Otherwise, *more* shall execute the user command specified.

100044 Several of the commands described in this section display a previous screen from the input
100045 stream. In the case that text is being taken from a non-rewindable stream, such as a pipe, it is
100046 implementation-defined how much backwards motion is supported. If a command cannot be
100047 executed because of a limitation on backwards motion, an error message to this effect shall be
100048 displayed, the current screen shall not change, and the user shall be prompted for another
100049 command.

100050 If a command cannot be performed because there are insufficient lines to display, *more* shall alert
100051 the terminal. If a command cannot be performed because there are insufficient lines to display or
100052 a **/** command fails: if the input is the standard input, the last screen in the file may be displayed;
100053 otherwise, the current file and screen shall not change, and the user shall be prompted for
100054 another command.

100055 The interactive commands in the following sections shall be supported. Some commands can be
100056 preceded by a decimal integer, called *count* in the following descriptions. If not specified with
100057 the command, *count* shall default to 1. In the following descriptions, *pattern* is a basic regular
100058 expression, as described in XBD Section 9.3 (on page 183). The term ``examine'' is historical
100059 usage meaning ``open the file for viewing''; for example, *more* **foo** would be expressed as
100060 examining file **foo**.

100061 In the following descriptions, unless otherwise specified, *line* is a line in the *more* display, not a
100062 line from the file being examined.

100063 In the following descriptions, the *current position* refers to two things:

100064 1. The position of the current line on the screen

100065 2. The line number (in the file) of the current line on the screen

100066 Usually, the line on the screen corresponding to the current position is the third line on the

100067 screen. If this is not possible (there are fewer than three lines to display or this is the first page of
100068 the file, or it is the last page of the file), then the current position is either the first or last line on
100069 the screen as described later.

100070 **Help**

100071 *Synopsis*: `h`

100072 Write a summary of these commands and other implementation-defined commands. The
100073 behavior shall be as if the *more* utility were executed with the −**e** option on a file that contained
100074 the summary information. The user shall be prompted as described earlier in this section when
100075 end-of-file is reached. If the user command is one of those specified to continue to the next file,
100076 *more* shall return to the file and screen state from which the **h** command was executed.

100077 **Scroll Forward One Screenful**

100078 *Synopsis*: **[***count***]**f
100079 **[***count***]**<control>−F

100080 Scroll forward *count* lines, with a default of one screenful. If *count* is more than the screen size,
100081 only the final screenful shall be written.

100082 **Scroll Backward One Screenful**

100083 *Synopsis*: **[***count***]**b
100084 **[***count***]**<control>−B

100085 Scroll backward *count* lines, with a default of one screenful (see the −**n** option). If *count* is more
100086 than the screen size, only the final screenful shall be written.

100087 **Scroll Forward One Line**

100088 *Synopsis*: **[***count***]**<space>
100089 **[***count***]**j
100090 **[***count***]**<newline>

100091 Scroll forward *count* lines. The default *count* for the <space> shall be one screenful; for **j** and
100092 <newline>, one line. The entire *count* lines shall be written, even if *count* is more than the screen
100093 size.

100094 **Scroll Backward One Line**

100095 *Synopsis*: **[***count***]**k

100096 Scroll backward *count* lines. The entire *count* lines shall be written, even if *count* is more than the
100097 screen size.

100098 **Scroll Forward One Half Screenful**

100099 *Synopsis*: **[***count***]**d
100100 **[***count***]**<control>−D

100101 Scroll forward *count* lines, with a default of one half of the screen size. If *count* is specified, it
100102 shall become the new default for subsequent **d**, <control>-D, and **u** commands.

100103 **Skip Forward One Line**

100104 *Synopsis*: **[***count***]**s

100105 Display the screenful beginning with the line *count* lines after the last line on the current screen.
100106 If *count* would cause the current position to be such that less than one screenful would be
100107 written, the last screenful in the file shall be written.

100108 **Scroll Backward One Half Screenful**

100109 *Synopsis*: **[***count***]**u
100110 **[***count***]**<control>–U

100111 Scroll backward *count* lines, with a default of one half of the screen size. If *count* is specified, it
100112 shall become the new default for subsequent **d**, <control>–D, **u**, and <control>–U commands.
100113 The entire *count* lines shall be written, even if *count* is more than the screen size.

100114 **Go to Beginning of File**

100115 *Synopsis*: **[***count***]**g

100116 Display the screenful beginning with line *count*.

100117 **Go to End-of-File**

100118 *Synopsis*: **[***count***]**G

100119 If *count* is specified, display the screenful beginning with the line *count*. Otherwise, display the
100120 last screenful of the file.

100121 **Refresh the Screen**

100122 *Synopsis*: r
100123 <control>–L

100124 Refresh the screen.

100125 **Discard and Refresh**

100126 *Synopsis*: R

100127 Refresh the screen, discarding any buffered input. If the current file is non-seekable, buffered
100128 input shall not be discarded and the **R** command shall be equivalent to the **r** command.

100129 **Mark Position**

100130 *Synopsis*: m*letter*

100131 Mark the current position with the letter named by *letter*, where *letter* represents the name of one
100132 of the lowercase letters of the portable character set. When a new file is examined, all marks may
100133 be lost.

100134 **Return to Mark**

100135 *Synopsis*: `'`*letter*

100136 Return to the position that was previously marked with the letter named by *letter*, making that
100137 line the current position.

100138 **Return to Previous Position**

100139 *Synopsis*: `''`

100140 Return to the position from which the last large movement command was executed (where a
100141 ``large movement'' is defined as any movement of more than a screenful of lines). If no such
100142 movements have been made, return to the beginning of the file.

100143 **Search Forward for Pattern**

100144 *Synopsis*: **[***count***]/[!]***pattern*<newline>

100145 Display the screenful beginning with the *count*th line containing the pattern. The search shall
100146 start after the first line currently displayed. The null regular expression (`'/'` followed by a
100147 <newline>) shall repeat the search using the previous regular expression, with a default *count*. If
100148 the character `'!'` is included, the matching lines shall be those that do not contain the *pattern*. If
100149 no match is found for the *pattern*, a message to that effect shall be displayed.

100150 **Search Backward for Pattern**

100151 *Synopsis*: **[***count***]?[!]***pattern*<newline>

100152 Display the screenful beginning with the *count*th previous line containing the pattern. The search
100153 shall start on the last line before the first line currently displayed. The null regular expression
100154 (`'?'` followed by a <newline>) shall repeat the search using the previous regular expression,
100155 with a default *count*. If the character `'!'` is included, matching lines shall be those that do not
100156 contain the *pattern*. If no match is found for the *pattern*, a message to that effect shall be
100157 displayed.

100158 **Repeat Search**

100159 *Synopsis*: **[***count***]**n

100160 Repeat the previous search for *count*th line containing the last *pattern* (or not containing the last
100161 *pattern*, if the previous search was `"/!"` or `"?!"`).

100162 **Repeat Search in Reverse**

100163 *Synopsis*: **[***count***]**N

100164 Repeat the search in the opposite direction of the previous search for the *count*th line containing
100165 the last *pattern* (or not containing the last *pattern*, if the previous search was `"/!"` or `"?!"`).

100166 **Examine New File**

100167 *Synopsis*: `:e [`*`filename`*`]`<newline>

100168 Examine a new file. If the *filename* argument is not specified, the current file (see the **:n** and **:p**
100169 commands below) shall be re-examined. The *filename* shall be subjected to the process of shell
100170 word expansions (see Section 2.6, on page 2353); if more than a single pathname results, the
100171 effects are unspecified. If *filename* is a <number-sign> (`'#'`), the previously examined file shall
100172 be re-examined. If *filename* is not accessible for any reason (including that it is a non-seekable
100173 file), an error message to this effect shall be displayed and the current file and screen shall not
100174 change.

100175 **Examine Next File**

100176 *Synopsis*: `[`*`count`*`]:n`

100177 Examine the next file. If a number *count* is specified, the *count*th next file shall be examined. If
100178 *filename* refers to a non-seekable file, the results are unspecified.

100179 **Examine Previous File**

100180 *Synopsis*: `[`*`count`*`]:p`

100181 Examine the previous file. If a number *count* is specified, the *count*th previous file shall be
100182 examined. If *filename* refers to a non-seekable file, the results are unspecified.

100183 **Go to Tag**

100184 *Synopsis*: `:t` *`tagstring`*<newline>

100185 If the file containing the tag named by the *tagstring* argument is not the current file, examine the
100186 file, as if the **:e** command was executed with that file as the argument. Otherwise, or in addition,
100187 display the screenful beginning with the tag, as described for the **−t** option (see the OPTIONS
100188 section). If the *ctags* utility is not supported by the system, the use of **:t** produces undefined
100189 results.

100190 **Invoke Editor**

100191 *Synopsis*: `v`

100192 Invoke an editor to edit the current file being examined. If standard input is being examined, the
100193 results are unspecified. The name of the editor shall be taken from the environment variable
100194 *EDITOR*, or shall default to *vi*. If the last pathname component in *EDITOR* is either *vi* or *ex*, the
100195 editor shall be invoked with a **−c** *linenumber* command line argument, where *linenumber* is the
100196 line number of the file line containing the display line currently displayed as the first line of the
100197 screen. It is implementation-defined whether line-setting options are passed to editors other
100198 than *vi* and *ex*.

100199 When the editor exits, *more* shall resume with the same file and screen as when the editor was
100200 invoked.

100201 **Display Position**

100202 *Synopsis*: `=`
100203 `<control>-G`

100204 Write a message for which the information references the first byte of the line after the last line of
100205 the file on the screen. This message shall include the name of the file currently being examined,
100206 its number relative to the total number of files there are to examine, the line number in the file,
100207 the byte number and the total bytes in the file, and what percentage of the file precedes the
100208 current position. If *more* is reading from standard input, or the file is shorter than a single screen,
100209 the line number, the byte number, the total bytes, and the percentage need not be written.

100210 **Quit**

100211 *Synopsis*: `q`
100212 `:q`
100213 `ZZ`

100214 Exit *more*.

100215 **EXIT STATUS**

100216 The following exit values shall be returned:

100217 0 Successful completion.

100218 >0 An error occurred.

100219 **CONSEQUENCES OF ERRORS**

100220 If an error is encountered accessing a file when using the **:n** command, *more* shall attempt to
100221 examine the next file in the argument list, but the final exit status shall be affected. If an error is
100222 encountered accessing a file via the **:p** command, *more* shall attempt to examine the previous file
100223 in the argument list, but the final exit status shall be affected. If an error is encountered accessing
100224 a file via the **:e** command, *more* shall remain in the current file and the final exit status shall not
100225 be affected.

100226 **APPLICATION USAGE**

100227 When the standard output is not a terminal, only the −**s** filter-modification option is effective.
100228 This is based on historical practice. For example, a typical implementation of *man* pipes its
100229 output through *more* −**s** to squeeze excess white space for terminal users. When *man* is piped to
100230 *lp*, however, it is undesirable for this squeezing to happen.

100231 **EXAMPLES**

100232 The −**p** allows arbitrary commands to be executed at the start of each file. Examples are:

100233 *more* −**p G** *file1 file2*
100234 Examine each file starting with its last screenful.

100235 *more* −**p** 100 *file1 file2*
100236 Examine each file starting with line 100 in the current position (usually the third line, so line
100237 98 would be the first line written).

100238 *more* −**p** /100 *file1 file2*
100239 Examine each file starting with the first line containing the string `"100"` in the current
100240 position

RATIONALE

The *more* utility, available in BSD and BSD-derived systems, was chosen as the prototype for the POSIX file display program since it is more widely available than either the public-domain program *less* or than *pg*, a pager provided in System V. The 4.4 BSD *more* is the model for the features selected; it is almost fully upwards-compatible from the 4.3 BSD version in wide use and has become more amenable for *vi* users. Several features originally derived from various file editors, found in both *less* and *pg*, have been added to this volume of POSIX.1-2017 as they have proved extremely popular with users.

There are inconsistencies between *more* and *vi* that result from historical practice. For example, the single-character commands **h**, **f**, **b**, and <space> are screen movers in *more*, but cursor movers in *vi*. These inconsistencies were maintained because the cursor movements are not applicable to *more* and the powerful functionality achieved without the use of the control key justifies the differences.

The tags interface has been included in a program that is not a text editor because it promotes another degree of consistent operation with *vi*. It is conceivable that the paging environment of *more* would be superior for browsing source code files in some circumstances.

The operating mode referred to for block-mode terminals effectively adds a <newline> to each Synopsis line that currently has none. So, for example, **d**<newline> would page one screenful. The mode could be triggered by a command line option, environment variable, or some other method. The details are not imposed by this volume of POSIX.1-2017 because there are so few systems known to support such terminals. Nevertheless, it was considered that all systems should be able to support *more* given the exception cited for this small community of terminals because, in comparison to *vi*, the cursor movements are few and the command set relatively amenable to the optional <newline> characters.

Some versions of *more* provide a shell escaping mechanism similar to the *ex* **!** command. The standard developers did not consider that this was necessary in a paginator, particularly given the wide acceptance of multiple window terminals and job control features. (They chose to retain such features in the editors and *mailx* because the shell interaction also gives an opportunity to modify the editing buffer, which is not applicable to *more*.)

The **−p** (position) option replaces the **+** command because of the Utility Syntax Guidelines. The *+command* option is no longer specified by POSIX.1-2017 but may be present in some implementations. In early proposals, it took a *pattern* argument, but historical *less* provided the *more* general facility of a command. It would have been desirable to use the same **−c** as *ex* and *vi*, but the letter was already in use.

The text stating ``from a non-rewindable stream ... implementations may limit the amount of backwards motion supported'' would allow an implementation that permitted no backwards motion beyond text already on the screen. It was not possible to require a minimum amount of backwards motion that would be effective for all conceivable device types. The implementation should allow the user to back up as far as possible, within device and reasonable memory allocation constraints.

Historically, non-printable characters were displayed using the ARPA standard mappings, which are as follows:

1. Printable characters are left alone.
2. Control characters less than \177 are represented as followed by the character offset from the `'@'` character in the ASCII map; for example, \007 is represented as `'G'`.

100286 3. \177 is represented as followed by '?'.

100287 The display of characters having their eighth bit set was less standard. Existing implementations
100288 use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed characters with their
100289 eighth bit set as the two characters "M-", followed by the seven-bit display as described
100290 previously.) The latter probably has the best claim to historical practice because it was used with
100291 the **-v** option of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

100292 No specific display format is required by POSIX.1-2017. Implementations are encouraged to
100293 conform to historic practice in the absence of any strong reason to diverge.

100294 **FUTURE DIRECTIONS**

100295 None.

100296 **SEE ALSO**

100297 Chapter 2 (on page 2345), *ctags*, *ed*, *ex*, *vi*

100298 XBD Chapter 8 (on page 173), Section 9.2 (on page 182), Section 9.3 (on page 183), Section 12.2
100299 (on page 216)

100300 **CHANGE HISTORY**

100301 First released in Issue 4.

100302 **Issue 5**

100303 The FUTURE DIRECTIONS section is added.

100304 **Issue 6**

100305 This utility is marked as part of the User Portability Utilities option.

100306 The obsolescent SYNOPSIS is removed.

100307 The utility has been extensively reworked for alignment with the IEEE P1003.2b draft standard:

100308 Changes have been made as a result of IEEE PASC Interpretations 1003.2 #37 and #109.

100309 The *more* utility should be able to handle underlined and emboldened displays of
100310 characters that are wider than a single column position.

100311 **Issue 7**

100312 Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that '+' may be recognized
100313 as an option delimiter in the OPTIONS section.

100314 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

100315 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0123 [265] is applied.

100316 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0146 [584] is applied.

100317 **NAME**

100318 mv ‡'move files

100319 **SYNOPSIS**

100320 `mv [-if] source_file target_file`

100321 `mv [-if] source_file... target_dir`

100322 **DESCRIPTION**

100323 In the first synopsis form, the *mv* utility shall move the file named by the *source_file* operand to
100324 the destination specified by the *target_file*. This first synopsis form is assumed when the final
100325 operand does not name an existing directory and is not a symbolic link referring to an existing
100326 directory. In this case, if *source_file* names a non-directory file and *target_file* ends with a trailing
100327 <slash> character, *mv* shall treat this as an error and no *source_file* operands will be processed.

100328 In the second synopsis form, *mv* shall move each file named by a *source_file* operand to a
100329 destination file in the existing directory named by the *target_dir* operand, or referenced if
100330 *target_dir* is a symbolic link referring to an existing directory. The destination path for each
100331 *source_file* shall be the concatenation of the target directory, a single <slash> character if the
100332 target did not end in a <slash>, and the last pathname component of the *source_file*. This second
100333 form is assumed when the final operand names an existing directory.

100334 If any operand specifies an existing file of a type not specified by the System Interfaces volume
100335 of POSIX.1-2017, the behavior is implementation-defined.

100336 For each *source_file* the following steps shall be taken:

100337 1. If the destination path exists, the **−f** option is not specified, and either of the following
100338 conditions is true:

100339 a. The permissions of the destination path do not permit writing and the standard
100340 input is a terminal.

100341 b. The **−i** option is specified.

100342 the *mv* utility shall write a prompt to standard error and read a line from standard input.
100343 If the response is not affirmative, *mv* shall do nothing more with the current *source_file*
100344 and go on to any remaining *source_file*s.

100345 2. If the *source_file* operand and destination path resolve to either the same existing directory
100346 entry or different directory entries for the same existing file, then the destination path
100347 shall not be removed, and one of the following shall occur:

100348 a. No change is made to *source_file*, no error occurs, and no diagnostic is issued.

100349 b. No change is made to *source_file*, a diagnostic is issued to standard error
100350 identifying the two names, and the exit status is affected.

100351 c. If the *source_file* operand and destination path name distinct directory entries, then
100352 the *source_file* operand is removed, no error occurs, and no diagnostic is issued.

100353 The *mv* utility shall do nothing more with the current *source_file*, and go on to any
100354 remaining *source_file*s.

100355 3. The *mv* utility shall perform actions equivalent to the *rename*() function defined in the
100356 System Interfaces volume of POSIX.1-2017, called with the following arguments:

100357 a. The *source_file* operand is used as the *old* argument.

100358 b. The destination path is used as the *new* argument.

100359 If this succeeds, *mv* shall do nothing more with the current *source_file* and go on to any
100360 remaining *source_file*s. If this fails for any reasons other than those described for the *errno*
100361 [EXDEV] in the System Interfaces volume of POSIX.1-2017, *mv* shall write a diagnostic
100362 message to standard error, do nothing more with the current *source_file*, and go on to any
100363 remaining *source_file*s.

100364 4. If the destination path exists, and it is a file of type directory and *source_file* is not a file of
100365 type directory, or it is a file not of type directory and *source_file* is a file of type directory,
100366 *mv* shall write a diagnostic message to standard error, do nothing more with the current
100367 *source_file*, and go on to any remaining *source_file*s. If the destination path exists and was
100368 created by a previous step, it is unspecified whether this will treated as an error or the
100369 destination path will be overwritten.

100370 5. If the destination path exists, *mv* shall attempt to remove it. If this fails for any reason, *mv*
100371 shall write a diagnostic message to standard error, do nothing more with the current
100372 *source_file*, and go on to any remaining *source_file*s.

100373 6. The file hierarchy rooted in *source_file* shall be duplicated as a file hierarchy rooted in the
100374 destination path. If *source_file* or any of the files below it in the hierarchy are symbolic
100375 links, the links themselves shall be duplicated, including their contents, rather than any
100376 files to which they refer. The following characteristics of each file in the file hierarchy
100377 shall be duplicated:

100378 The time of last data modification and time of last access

100379 The user ID and group ID

100380 The file mode

100381 If the user ID, group ID, or file mode of a regular file cannot be duplicated, the file mode
100382 bits S_ISUID and S_ISGID shall not be duplicated.

100383 When files are duplicated to another file system, the implementation may require that the
100384 process invoking *mv* has read access to each file being duplicated.

100385 If files being duplicated to another file system have hard links to other files, it is
100386 unspecified whether the files copied to the new file system have the hard links preserved
100387 or separate copies are created for the linked files.

100388 If the duplication of the file hierarchy fails for any reason, *mv* shall write a diagnostic
100389 message to standard error, do nothing more with the current *source_file*, and go on to any
100390 remaining *source_file*s.

100391 If the duplication of the file characteristics fails for any reason, *mv* shall write a diagnostic
100392 message to standard error, but this failure shall not cause *mv* to modify its exit status.

100393 7. The file hierarchy rooted in *source_file* shall be removed. If this fails for any reason, *mv*
100394 shall write a diagnostic message to the standard error, do nothing more with the current
100395 *source_file*, and go on to any remaining *source_file*s.

100396 **OPTIONS**

100397 The *mv* utility shall conform to XBD Section 12.2 (on page 216).

100398 The following options shall be supported:

100399 **–f** Do not prompt for confirmation if the destination path exists. Any previous
100400 occurrence of the **–i** option is ignored.

100401 **–i** Prompt for confirmation if the destination path exists. Any previous occurrence of
100402 the **–f** option is ignored.

100403 Specifying more than one of the **–f** or **–i** options shall not be considered an error. The last option
100404 specified shall determine the behavior of *mv*.

100405 **OPERANDS**

100406 The following operands shall be supported:

100407 *source_file* A pathname of a file or directory to be moved.

100408 *target_file* A new pathname for the file or directory being moved.

100409 *target_dir* A pathname of an existing directory into which to move the input files.

100410 **STDIN**

100411 The standard input shall be used to read an input line in response to each prompt specified in
100412 the STDERR section. Otherwise, the standard input shall not be used.

100413 **INPUT FILES**

100414 The input files specified by each *source_file* operand can be of any file type.

100415 **ENVIRONMENT VARIABLES**

100416 The following environment variables shall affect the execution of *mv*:

100417 *LANG* Provide a default value for the internationalization variables that are unset or null.
100418 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
100419 variables used to determine the values of locale categories.)

100420 *LC_ALL* If set to a non-empty string value, override the values of all the other
100421 internationalization variables.

100422 *LC_COLLATE*
100423 Determine the locale for the behavior of ranges, equivalence classes, and multi-
100424 character collating elements used in the extended regular expression defined for
100425 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

100426 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
100427 characters (for example, single-byte as opposed to multi-byte characters in
100428 arguments and input files), the behavior of character classes used in the extended
100429 regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES*
100430 category.

100431 *LC_MESSAGES*
100432 Determine the locale used to process affirmative responses, and the locale used to
100433 affect the format and contents of diagnostic messages and prompts written to
100434 standard error.

100435 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

100436 **ASYNCHRONOUS EVENTS**

100437 Default.

100438 **STDOUT**

100439 Not used.

100440 **STDERR**

100441 Prompts shall be written to the standard error under the conditions specified in the
100442 DESCRIPTION section. The prompts shall contain the destination pathname, but their format is
100443 otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic

messages.

OUTPUT FILES

The output files may be of any file type.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were moved successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If the copying or removal of *source_file* is prematurely terminated by a signal or error, *mv* may leave a partial copy of *source_file* at the source or destination. The *mv* utility shall not modify both *source_file* and the destination path simultaneously; termination at any point shall leave either *source_file* or the destination path complete.

APPLICATION USAGE

Some implementations mark for update the last file status change timestamp of renamed files and some do not. Applications which make use of the last file status change timestamp may behave differently with respect to renamed files unless they are designed to allow for either behavior.

The specification ensures that *mv* **a** **a** will not alter the contents of file **a**, and allows the implementation to issue an error that a file cannot be moved onto itself. Likewise, when **a** and **b** are hard links to the same file, *mv* **a** **b** will not alter **b**, but if a diagnostic is not issued, then it is unspecified whether **a** is left untouched (as it would be by the *rename*() function) or unlinked (reducing the link count of **b**).

EXAMPLES

If the current directory contains only files **a** (of any type defined by the System Interfaces volume of POSIX.1-2017), **b** (also of any type), and a directory **c**:

```
mv a b c
mv c d
```

results with the original files **a** and **b** residing in the directory **d** in the current directory.

RATIONALE

Early proposals diverged from the SVID and BSD historical practice in that they required that when the destination path exists, the **−f** option is not specified, and input is not a terminal, *mv* fails. This was done for compatibility with *cp*. The current text returns to historical practice. It should be noted that this is consistent with the *rename*() function defined in the System Interfaces volume of POSIX.1-2017, which does not require write permission on the target.

For absolute clarity, paragraph (1), describing the behavior of *mv* when prompting for confirmation, should be interpreted in the following manner:

```
if (exists AND (NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The **−i** option exists on BSD systems, giving applications and users a way to avoid accidentally unlinking files when moving others. When the standard input is not a terminal, the 4.3 BSD *mv* deletes all existing destination paths without prompting, even when **−i** is specified; this is inconsistent with the behavior of the 4.3 BSD *cp* utility, which always generates an error when

the file is unwritable and the standard input is not a terminal. The standard developers decided that use of **−i** is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds to standard input.
