The *rename*( ) function is able to move directories within the same file system. Some historical versions of *mv* have been able to move directories, but not to a different file system. The standard developers considered that this was an annoying inconsistency, so this volume of POSIX.1-2017 requires directories to be able to be moved even across file systems. There is no **−R** option to confirm that moving a directory is actually intended, since such an option was not required for moving directories in historical practice. Requiring the application to specify it sometimes, depending on the destination, seemed just as inconsistent. The semantics of the *rename*( ) function were preserved as much as possible. For example, *mv* is not permitted to ``rename'' files to or from directories, even though they might be empty and removable.

Historic implementations of *mv* did not exit with a non-zero exit status if they were unable to duplicate any file characteristics when moving a file across file systems, nor did they write a diagnostic message for the user. The former behavior has been preserved to prevent scripts from breaking; a diagnostic message is now required, however, so that users are alerted that the file characteristics have changed.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the **−f** option or using the **−i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

When *mv* is dealing with a single file system and *source_file* is a symbolic link, the link itself is moved as a consequence of the dependence on the *rename*( ) functionality, per the DESCRIPTION. Across file systems, this has to be made explicit.

FUTURE DIRECTIONS

None.

XSH *rename*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The *mv* utility is changed to describe processing of symbolic links as specified in the IEEE P1003.2b draft standard.

The APPLICATION USAGE section is added.

Issue 7

Austin Group Interpretation 1003.1-2001 #016 is applied.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

Austin Group Interpretations 1003.1-2001 #164, #168, and #169 are applied.

SD5-XCU-ERN-13 is applied, making an editorial correction to the SYNOPSIS.

SD5-XCU-ERN-51 is applied to the DESCRIPTION, defining the behavior for when files are

being duplicated to another file system while having hard links.

Changes are made related to support for finegrained timestamps.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0124 [48] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0147 [534] is applied.

NAME

newgrp — change to a new group

SYNOPSIS

```
newgrp [-l] [group]
```

DESCRIPTION

The *newgrp* utility shall create a new shell execution environment with a new real and effective group identification. Of the attributes listed in Section 2.12 (on page 2381), the new shell execution environment shall retain the working directory, file creation mask, and exported variables from the previous environment (that is, open files, traps, unexported variables, alias definitions, shell functions, and *set* options may be lost). All other aspects of the process environment that are preserved by the *exec* family of functions defined in the System Interfaces volume of POSIX.1-2017 shall also be preserved by *newgrp*; whether other aspects are preserved is unspecified.

A failure to assign the new group identifications (for example, for security or password-related reasons) shall not prevent the new shell execution environment from being created.

The *newgrp* utility shall affect the supplemental groups for the process as follows:

On systems where the effective group ID is normally in the supplementary group list (or whenever the old effective group ID actually is in the supplementary group list):

- If the new effective group ID is also in the supplementary group list, *newgrp* shall change the effective group ID.
- If the new effective group ID is not in the supplementary group list, *newgrp* shall add the new effective group ID to the list, if there is room to add it.

On systems where the effective group ID is not normally in the supplementary group list (or whenever the old effective group ID is not in the supplementary group list):

- If the new effective group ID is in the supplementary group list, *newgrp* shall delete it.
- If the old effective group ID is not in the supplementary list, *newgrp* shall add it if there is room.

Note: The System Interfaces volume of POSIX.1-2017 does not specify whether the effective group ID of a process is included in its supplementary group list.

With no operands, *newgrp* shall change the effective group back to the groups identified in the user's user entry, and shall set the list of supplementary groups to that set in the user's group database entries.

If the first argument is `'-'`, the results are unspecified.

If a password is required for the specified group, and the user is not listed as a member of that group in the group database, the user shall be prompted to enter the correct password for that group. If the user is listed as a member of that group, no password shall be requested. If no password is required for the specified group, it is implementation-defined whether users not listed as members of that group can change to that group. Whether or not a password is required, implementation-defined system accounting or security mechanisms may impose additional authorization restrictions that may cause *newgrp* to write a diagnostic message and suppress the changing of the group identification.

OPTIONS

The *newgrp* utility shall conform to XBD Section 12.2 (on page 216), except for the unspecified usage of '−'.

The following option shall be supported:

−l (The letter ell.) Change the environment to what would be expected if the user actually logged in again.

OPERANDS

The following operand shall be supported:

group A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs shall be set. If *group* is a non-negative numeric string and exists in the group database as a group name (see *getgrnam*()), the numeric group ID associated with that group name shall be used as the group ID.

STDIN

Not used.

INPUT FILES

The file **/dev/tty** shall be used to read a single line of text for password checking, when one is required.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *newgrp*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic messages and a prompt string for a password, if one is required. Diagnostic messages may be written in cases where the exit status is not available. See the EXIT STATUS section.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *newgrp* succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status shall be the exit status of the shell. Otherwise, the following exit value shall be returned:

>0 An error occurred.

CONSEQUENCES OF ERRORS

The invoking shell may terminate.

APPLICATION USAGE

There is no convenient way to enter a password into the group database. Use of group passwords is not encouraged, because by their very nature they encourage poor security practices. Group passwords may disappear in the future.

A common implementation of *newgrp* is that the current shell uses *exec* to overlay itself with *newgrp*, which in turn overlays itself with a new shell after changing group. On some implementations, however, this may not occur and *newgrp* may be invoked as a subprocess.

The *newgrp* command is intended only for use from an interactive terminal. It does not offer a useful interface for the support of applications.

The exit status of *newgrp* is generally inapplicable. If *newgrp* is used in a script, in most cases it successfully invokes a new shell and the rest of the original shell script is bypassed when the new shell exits. Used interactively, *newgrp* displays diagnostic messages to indicate problems. But usage such as:

```
newgrp foo
echo $?
```

is not useful because the new shell might not have access to any status *newgrp* may have generated (and most historical systems do not provide this status). A zero status echoed here does not necessarily indicate that the user has changed to the new group successfully. Following *newgrp* with the *id* command provides a portable means of determining whether the group change was successful or not.

EXAMPLES

None.

RATIONALE

Most historical implementations use one of the *exec* functions to implement the behavior of *newgrp*. Errors detected before the *exec* leave the environment unchanged, while errors detected after the *exec* leave the user in a changed environment. While it would be useful to have *newgrp* issue a diagnostic message to tell the user that the environment changed, it would be inappropriate to require this change to some historical implementations.

The password mechanism is allowed in the group database, but how this would be implemented is not specified.

The *newgrp* utility was retained in this volume of POSIX.1-2017, even given the existence of the multiple group permissions feature in the System Interfaces volume of POSIX.1-2017, for several reasons. First, in some implementations, the group ownership of a newly created file is determined by the group of the directory in which the file is created, as allowed by the System

Interfaces volume of POSIX.1-2017; on other implementations, the group ownership of a newly created file is determined by the effective group ID. On implementations of the latter type, *newgrp* allows files to be created with a specific group ownership. Finally, many implementations use the real group ID in accounting, and on such systems, *newgrp* allows the accounting identity of the user to be changed.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

XSH *exec*, *getgrnam*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The text describing supplemental groups is no longer conditional on {NGROUPS_MAX} being greater than 1. This is because {NGROUPS_MAX} now has a minimum value of 8. This is a FIPS requirement.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first argument is `'-'`.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *newgrp* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

nice — invoke a utility with an altered nice value

SYNOPSIS

```
nice [−n increment] utility [argument...]
```

DESCRIPTION

The *nice* utility shall invoke a utility, requesting that it be run with a different nice value (see XBD Section 3.244, on page 72). With no options, the executed utility shall be run with a nice value that is some implementation-defined quantity greater than or equal to the nice value of the current process. If the user lacks appropriate privileges to affect the nice value in the requested manner, the *nice* utility shall not affect the nice value; in this case, a warning message may be written to standard error, but this shall not prevent the invocation of *utility* or affect the exit status.

OPTIONS

The *nice* utility shall conform to XBD Section 12.2 (on page 216).

The following option is supported:

−n *increment* A positive or negative decimal integer which shall have the same effect on the execution of the utility as if the utility had called the *nice*( ) function with the numeric value of the *increment* option-argument.

OPERANDS

The following operands shall be supported:

utility The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2384), the results are undefined.

argument Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nice*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

100730 *PATH* Determine the search path used to locate the utility to be invoked. See XBD
100731 Chapter 8 (on page 173).

100732 **ASYNCHRONOUS EVENTS**
100733 Default.

100734 **STDOUT**
100735 Not used.

100736 **STDERR**
100737 The standard error shall be used only for diagnostic messages.

100738 **OUTPUT FILES**
100739 None.

100740 **EXTENDED DESCRIPTION**
100741 None.

100742 **EXIT STATUS**
100743 If *utility* is invoked, the exit status of *nice* shall be the exit status of *utility*; otherwise, the *nice*
100744 utility shall exit with one of the following values:

100745 1-125 An error occurred in the *nice* utility.

100746 126 The utility specified by *utility* was found but could not be invoked.

100747 127 The utility specified by *utility* could not be found.

100748 **CONSEQUENCES OF ERRORS**
100749 Default.

100750 **APPLICATION USAGE**
100751 The only guaranteed portable uses of this utility are:

100752 *nice utility*
100753 Run *utility* with the default higher or equal nice value.

100754 *nice* **−n** <*positive integer*> *utility*
100755 Run *utility* with a higher nice value.

100756 On some implementations they have no discernible effect on the invoked utility and on some
100757 others they are exactly equivalent.

100758 Historical systems have frequently supported the <*positive integer*> up to 20. Since there is no
100759 error penalty associated with guessing a number that is too high, users without access to the
100760 system conformance document (to see what limits are actually in place) could use the historical 1
100761 to 20 range or attempt to use very large numbers if the job should be truly low priority.

100762 The nice value of a process can be displayed using the command:

100763 `ps −o nice`

100764 The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if
100765 an error occurs so that applications can distinguish ``failure to find a utility'' from ``invoked
100766 utility exited with an error indication''. The value 127 was chosen because it is not commonly
100767 used for other meanings; most utilities use small values for ``normal error conditions'' and the
100768 values above 128 can be confused with termination due to receipt of a signal. The value 126 was
100769 chosen in a similar manner to indicate that the utility could be found, but not invoked. Some
100770 scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction
100771 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
100772 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for

any other reason.

EXAMPLES

None.

RATIONALE

The 4.3 BSD version of *nice* does not check whether *increment* is a valid decimal integer. The command *nice* **–x** *utility*, for example, would be treated the same as the command *nice* **––1** *utility*. If the user does not have appropriate privileges, this results in a ``permission denied'' error. This is considered a bug.

When a user without appropriate privileges gives a negative *increment*, System V treats it like the command *nice* **–0** *utility*, while 4.3 BSD writes a ``permission denied'' message and does not run the utility. The standard specifies the System V behavior together with an optional BSD-style ``permission denied'' message.

The C shell has a built-in version of *nice* that has a different interface from the one described in this volume of POSIX.1-2017.

The term ``utility'' is used, rather than ``command'', to highlight the fact that shell compound commands, pipelines, and so on, cannot be used. Special built-ins also cannot be used. However, ``utility'' includes user application programs and shell scripts, not just utilities defined in this volume of POSIX.1-2017.

Historical implementations of *nice* provide a nice value range of 40 or 41 discrete steps, with the default nice value being the midpoint of that range. By default, they raise the nice value of the executed utility by 10.

Some historical documentation states that the *increment* value must be within a fixed range. This is misleading; the valid *increment* values on any invocation are determined by the current process nice value, which is not always the default.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of POSIX.1-2017 make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of POSIX.1-2017, and others may have no effect at all. Because of the use of ``implementation-defined'' in *nice* and *renice*, a wide range of implementation strategies are possible.

Earlier versions of this standard allowed a –*increment* option. This form is no longer specified by POSIX.1-2017 but may be present in some implementations.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/18 is applied, deleting a paragraph of RATIONALE that referred to text no longer in the standard.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied.

SD5-XCU-ERN-32 and SD5-XCU-ERN-33 are applied, updating the DESCRIPTION, APPLICATION USAGE, and RATIONALE sections.

The *nice* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

nl ‡′line numbering filter

SYNOPSIS

XSI
```
nl [−p] [−b type] [−d delim] [−f type] [−h type] [−i incr] [−l num]
    [−n format] [−s sep] [−v startnum] [−w width] [file]
```

DESCRIPTION

The *nl* utility shall read lines from the named *file* or the standard input if no *file* is named and shall reproduce the lines to standard output. Lines shall be numbered on the left. Additional functionality may be provided in accordance with the command options in effect.

The *nl* utility views the text it reads in terms of logical pages. Line numbering shall be reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (for example, no numbering of header and footer lines while numbering blank lines only in the body).

The starts of logical page sections shall be signaled by input lines containing nothing but the following delimiter characters:

Line	Start of
`\:\:\:`	Header
`\:\:`	Body
`\:`	Footer

Unless otherwise specified, *nl* shall assume the text being read is in a single logical page body.

OPTIONS

The *nl* utility shall conform to XBD Section 12.2 (on page 216). Only one file can be named.

The following options shall be supported:

−b *type* Specify which logical page body lines shall be numbered. Recognized *types* and their meaning are:

- **a** Number all lines.
- **t** Number only non-empty lines.
- **n** No line numbering.
- **p***string* Number only lines that contain the basic regular expression specified in *string*.

The default *type* for logical page body shall be **t** (text lines numbered).

−d *delim* Specify the delimiter characters that indicate the start of a logical page section. These can be changed from the default characters `"\:"` to two user-specified characters. If only one character is entered, the second character shall remain the default character `':'`.

−f *type* Specify the same as **b** *type* except for footer. The default for logical page footer shall be **n** (no lines numbered).

−h *type* Specify the same as **b** *type* except for header. The default *type* for logical page header shall be **n** (no lines numbered).

100866 100867 –**i** *incr* Specify the increment value used to number logical page lines. The default shall be 1.

100868 100869 100870 –**l** *num* Specify the number of blank lines to be considered as one. For example, –**l 2** results in only the second adjacent blank line being numbered (if the appropriate –**h a**, –**b a**, or –**f a** option is set). The default shall be 1.

100871 100872 100873 –**n** *format* Specify the line numbering format. Recognized values are: **ln**, left justified, leading zeros suppressed; **rn**, right justified, leading zeros suppressed; **rz**, right justified, leading zeros kept. The default *format* shall be **rn** (right justified).

100874 –**p** Specify that numbering should not be restarted at logical page delimiters.

100875 100876 –**s** *sep* Specify the characters used in separating the line number and the corresponding text line. The default *sep* shall be a <tab>.

100877 –**v** *startnum* Specify the initial value used to number logical page lines. The default shall be 1.

100878 100879 –**w** *width* Specify the number of characters to be used for the line number. The default *width* shall be 6.

100880 **OPERANDS**

100881 The following operand shall be supported:

100882 *file* A pathname of a text file to be line-numbered.

100883 **STDIN**

100884 100885 100886 The standard input shall be used if no *file* operand is specified, and shall be used if the *file* operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

100887 **INPUT FILES**

100888 The input file shall be a text file.

100889 **ENVIRONMENT VARIABLES**

100890 The following environment variables shall affect the execution of *nl*:

100891 100892 100893 *LANG* Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

100894 100895 *LC_ALL* If set to a non-empty string value, override the values of all the other internationalization variables.

100896 *LC_COLLATE*

100897 100898 Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

100899 100900 100901 100902 100903 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, and for deciding which characters are in character class **graph** (for the –**b t**, –**f t**, and –**h t** options).

100904 *LC_MESSAGES*

100905 100906 Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

100907 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

100908 **ASYNCHRONOUS EVENTS**

100909 Default.

100910 **STDOUT**

100911 The standard output shall be a text file in the following format:

100912 `"%s%s%s", <line number>, <separator>, <input line>`

100913 where <*line number*> is one of the following numeric formats:

100914 `%6d` When the **rn** format is used (the default; see −**n**).

100915 `%06d` When the **rz** format is used.

100916 `%−6d` When the **ln** format is used.

100917 <empty> When line numbers are suppressed for a portion of the page; the <*separator*> is also
100918 suppressed.

100919 In the preceding list, the number 6 is the default width; the −**w** option can change this value.

100920 **STDERR**

100921 The standard error shall be used only for diagnostic messages.

100922 **OUTPUT FILES**

100923 None.

100924 **EXTENDED DESCRIPTION**

100925 None.

100926 **EXIT STATUS**

100927 The following exit values shall be returned:

100928 0 Successful completion.

100929 >0 An error occurred.

100930 **CONSEQUENCES OF ERRORS**

100931 Default.

100932 **APPLICATION USAGE**

100933 In using the −**d** *delim* option, care should be taken to escape characters that have special meaning
100934 to the command interpreter.

100935 **EXAMPLES**

100936 The command:

100937 `nl −v 10 −i 10 −d \!+ file1`

100938 numbers *file1* starting at line number 10 with an increment of 10. The logical page delimiter is
100939 `"!+"`. Note that the `'!'` has to be escaped when using *csh* as a command interpreter because of
100940 its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but does not do any
100941 harm.

100942 **RATIONALE**

100943 None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The option [**–f** *type*] is added to the SYNOPSIS. The option descriptions are presented in alphabetic order. The description of **–bt** is changed to ``Number only non-empty lines''.

Issue 6

The obsolescent behavior allowing the options to be intermingled with the optional *file* operand is removed.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

nm ‡’write the name list of an object file(**DEVELOPMENT**)

SYNOPSIS

SD
```
nm [−APv] [−g|−u] [−t format] file...
```
XSI
```
nm [−APv] [−efox] [−g|−u] [−t format] file...
```

DESCRIPTION

The *nm* utility shall display symbolic information appearing in the object file, executable file, or object-file library named by *file*. If no symbolic information is available for a valid input file, the *nm* utility shall report that fact, but not consider it an error condition.

XSI The default base used when numeric values are written is unspecified. On XSI-conformant systems, it shall be decimal if the **−P** option is not specified.

OPTIONS

The *nm* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−A Write the full pathname or library name of an object on each line.

XSI **−e** Write only external (global) and static symbol information.

XSI **−f** Produce full output. Write redundant symbols (**.text**, **.data**, and **.bss**), normally suppressed.

−g Write only external (global) symbol information.

XSI **−o** Write numeric values in octal (equivalent to **−t o**).

−P Write information in a portable output format, as specified in the STDOUT section.

−t *format* Write each numeric value in the specified format. The format shall be dependent on the single character used as the *format* option-argument:

XSI `d` decimal (default if **−P** is not specified).

`o` octal.

`x` hexadecimal (default if **−P** is specified).

−u Write only undefined symbols.

−v Sort output by value instead of by symbol name.

XSI **−x** Write numeric values in hexadecimal (equivalent to **−t x**).

OPERANDS

The following operand shall be supported:

file A pathname of an object file, executable file, or object-file library.

STDIN

See the INPUT FILES section.

INPUT FILES

The input file shall be an object file, an object-file library whose format is the same as those produced by the *ar* utility for link editing, or an executable file. The *nm* utility may accept additional implementation-defined object library formats for the input file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nm*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for character collation information for the symbol-name and symbol-value collation sequences.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If symbolic information is present in the input files, then for each file or for each member of an archive, the *nm* utility shall write the following information to standard output. By default, the format is unspecified, but the output shall be sorted by symbol name according to the collation sequence in the current locale.

Library or object name, if −**A** is specified

Symbol name

Symbol type, which shall either be one of the following single characters or an implementation-defined type represented by a single character:

`A` Global absolute symbol.

`a` Local absolute symbol.

`B` Global ``bss'' (that is, uninitialized data space) symbol.

`b` Local bss symbol.

`D` Global data symbol.

`d` Local data symbol.

`T` Global text symbol.

`t` Local text symbol.

`U` Undefined symbol.

Value of the symbol

The size associated with the symbol, if applicable

This information may be supplemented by additional information specific to the

implementation.

If the **−P** option is specified, the previous information shall be displayed using the following portable format. The three versions differ depending on whether **−t d**, **−t o**, or **−t x** was specified, respectively:

```
"%s%s %s %d %d\n", <library/object name>, <name>, <type>,
    <value>, <size>

"%s%s %s %o %o\n", <library/object name>, <name>, <type>,
    <value>, <size>

"%s%s %s %x %x\n", <library/object name>, <name>, <type>,
    <value>, <size>
```

where <*library/object name*> shall be formatted as follows:

If **−A** is not specified, <*library/object name*> shall be an empty string.

If **−A** is specified and the corresponding *file* operand does not name a library:

```
"%s: ", <file>
```

If **−A** is specified and the corresponding *file* operand names a library. In this case, <*object file*> shall name the object file in the library containing the symbol being described:

```
"%s[%s]: ", <file>, <object file>
```

If **−A** is not specified, then if more than one *file* operand is specified or if only one *file* operand is specified and it names a library, *nm* shall write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

If the corresponding *file* operand does not name a library:

```
"%s:\n", <file>
```

If the corresponding *file* operand names a library; in this case, <*object file*> shall be the name of the file in the library containing the following symbols:

```
"%s[%s]:\n", <file>, <object file>
```

If **−P** is specified, but **−t** is not, the format shall be as if **−t x** had been specified.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Mechanisms for dynamic linking make this utility less meaningful when applied to an executable file because a dynamically linked executable may omit numerous library routines that would be found in a statically linked executable.

EXAMPLES

None.

RATIONALE

Historical implementations of *nm* have used different bases for numeric output and supplied different default types of symbols that were reported. The **−t** *format* option, similar to that used in *od* and *strings*, can be used to specify the numeric base; **−g** and **−u** can be used to restrict the amount of output or the types of symbols included in the output.

The compromise of using **−t** *format versus* using **−d**, **−o**, and other similar options was necessary because of differences in the meaning of **−o** between implementations. The **−o** option from BSD has been provided here as **−A** to avoid confusion with the **−o** from System V (which has been provided here as **−t** and as **−o** on XSI-conformant systems).

The option list was significantly reduced from that provided by historical implementations.

The *nm* description is a subset of both the System V and BSD *nm* utilities with no specified default output.

It was recognized that mechanisms for dynamic linking make this utility less meaningful when applied to an executable file (because a dynamically linked executable file may omit numerous library routines that would be found in a statically linked executable file), but the value of *nm* during software development was judged to outweigh other limitations.

The default output format of *nm* is not specified because of differences in historical implementations. The **−P** option was added to allow some type of portable output format. After a comparison of the different formats used in SunOS, BSD, SVR3, and SVR4, it was decided to create one that did not match the current format of any of these four systems. The format devised is easy to parse by humans, easy to parse in shell scripts, and does not need to vary depending on locale (because no English descriptions are included). All of the systems currently have the information available to use this format.

The format given in *nm* STDOUT uses <space> characters between the fields, which may be any number of <blank> characters required to align the columns. The single-character types were selected to match historical practice, and the requirement that implementation additions also be single characters made parsing the information easier for shell scripts.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as supported when both the User Portability Utilities option and the Software Development Utilities option are supported.

Issue 7

The *nm* utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0125 [263] and XCU/TC1-2008/0126 [263] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0148 [744] is applied.

NAME

nohup ‡'invoke a utility immune to hangups

SYNOPSIS

```
nohup utility [argument...]
```

DESCRIPTION

The *nohup* utility shall invoke the utility named by the *utility* operand with arguments supplied as the *argument* operands. At the time the named *utility* is invoked, the SIGHUP signal shall be set to be ignored.

If standard input is associated with a terminal, the *nohup* utility may redirect standard input from an unspecified file.

If the standard output is a terminal, all output written by the named *utility* to its standard output shall be appended to the end of the file **nohup.out** in the current directory. If **nohup.out** cannot be created or opened for appending, the output shall be appended to the end of the file **nohup.out** in the directory specified by the *HOME* environment variable. If neither file can be created or opened for appending, *utility* shall not be invoked. If a file is created, the file's permission bits shall be set to S_IRUSR | S_IWUSR.

If standard error is a terminal and standard output is open but is not a terminal, all output written by the named utility to its standard error shall be redirected to the same open file description as the standard output. If standard error is a terminal and standard output either is a terminal or is closed, the same output shall instead be appended to the end of the **nohup.out** file as described above.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

utility The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2384), the results are undefined.

argument Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nohup*:

HOME Determine the pathname of the user's home directory: if the output file **nohup.out** cannot be created in the current directory, the *nohup* utility shall use the directory named by *HOME* to create the file.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path that is used to locate the utility to be invoked. See XBD Chapter 8 (on page 173).

ASYNCHRONOUS EVENTS

The *nohup* utility shall take the standard action for all signals except that SIGHUP shall be ignored.

STDOUT

If the standard output is not a terminal, the standard output of *nohup* shall be the standard output generated by the execution of the *utility* specified by the operands. Otherwise, nothing shall be written to the standard output.

STDERR

If the standard output is a terminal, a message shall be written to the standard error, indicating the name of the file to which the output is being appended. The name of the file shall be either **nohup.out** or **$HOME/nohup.out**.

OUTPUT FILES

Output written by the named utility is appended to the file **nohup.out** (or **$HOME/nohup.out**), if the conditions hold as described in the DESCRIPTION.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

126 The utility specified by *utility* was found but could not be invoked.

127 An error occurred in the *nohup* utility or the utility specified by *utility* could not be found.

Otherwise, the exit status of *nohup* shall be that of the utility specified by the *utility* operand.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ``failure to find a utility'' from ``invoked utility exited with an error indication''. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ``normal error conditions'' and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

It is frequently desirable to apply *nohup* to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the *nohup* applies to everything in the file.

Alternatively, the following command can be used to apply *nohup* to a complex command:

```
nohup sh -c 'complex-command-line' </dev/null
```

RATIONALE

The 4.3 BSD version ignores SIGTERM and SIGHUP, and if **./nohup.out** cannot be used, it fails instead of trying to use **$HOME/nohup.out**.

The *csh* utility has a built-in version of *nohup* that acts differently from the *nohup* defined in this volume of POSIX.1-2017.

The term *utility* is used, rather than *command*, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility* includes user application programs and shell scripts, not just the standard utilities.

Historical versions of the *nohup* utility use default file creation semantics. Some more recent versions use the permissions specified here as an added security precaution.

Some historical implementations ignore SIGQUIT in addition to SIGHUP; others ignore SIGTERM. An early proposal allowed, but did not require, SIGQUIT to be ignored. Several reviewers objected that *nohup* should only modify the handling of SIGHUP as required by this volume of POSIX.1-2017.

Historical versions of *nohup* did not affect standard input, but that causes problems in the common scenario where the user logs into a system, types the command:

```
nohup make &
```

at the prompt, and then logs out. If standard input is not affected by *nohup*, the login session may not terminate for quite some time, since standard input remains open until *make* exits. To avoid this problem, POSIX.1-2017 allows implementations to redirect standard input if it is a terminal. Since the behavior is implementation-defined, portable applications that may run into the problem should redirect standard input themselves. For example, instead of:

```
nohup make &
```

an application can invoke:

```
nohup make </dev/null &
```

CHANGE HISTORY

First released in Issue 2.

Issue 7

Austin Group Interpretations 1003.1-2001 #104, #105, and #106 are applied.

NAME

od ‡'dump files in various formats

SYNOPSIS

```
od [−v] [−A address_base] [−j skip] [−N count] [−t type_string]...
    [file...]
```

XSI

```
od [−bcdosx] [file] [[+]offset[.][b]]
```

DESCRIPTION

The *od* utility shall write the contents of its input files to standard output in a user-specified format.

OPTIONS

The *od* utility shall conform to XBD Section 12.2 (on page 216), except that the order of presentation of the **−t** options and the **−bcdosx** options is significant.

The following options shall be supported:

−A *address_base*
: Specify the input offset base. See the EXTENDED DESCRIPTION section. The application shall ensure that the *address_base* option-argument is a character. The characters `'d'`, `'o'`, and `'x'` specify that the offset base shall be written in decimal, octal, or hexadecimal, respectively. The character `'n'` specifies that the offset shall not be written.

XSI **−b**
: Interpret bytes in octal. This shall be equivalent to **−t o1**.

XSI **−c**
: Interpret bytes as characters specified by the current setting of the *LC_CTYPE* category. Certain non-graphic characters appear as C escapes: `"NUL=\0"`, `"BS=\b"`, `"FF=\f"`, `"NL=\n"`, `"CR=\r"`, `"HT=\t"`; others appear as 3-digit octal numbers.

XSI **−d**
: Interpret *word*s (two-byte units) in unsigned decimal. This shall be equivalent to **−t u2**.

−j *skip*
: Jump over *skip* bytes from the beginning of the input. The *od* utility shall read or seek past the first *skip* bytes in the concatenated input files. If the combined input is not at least *skip* bytes long, the *od* utility shall write a diagnostic message to standard error and exit with a non-zero exit status.

  By default, the *skip* option-argument shall be interpreted as a decimal number. With a leading 0x or 0X, the offset shall be interpreted as a hexadecimal number; otherwise, with a leading `'0'`, the offset shall be interpreted as an octal number. Appending the character `'b'`, `'k'`, or `'m'` to offset shall cause it to be interpreted as a multiple of 512, 1 024, or 1 048 576 bytes, respectively. If the *skip* number is hexadecimal, any appended `'b'` shall be considered to be the final hexadecimal digit.

−N *count*
: Format no more than *count* bytes of input. By default, *count* shall be interpreted as a decimal number. With a leading 0x or 0X, *count* shall be interpreted as a hexadecimal number; otherwise, with a leading `'0'`, it shall be interpreted as an octal number. If *count* bytes of input (after successfully skipping, if **−j** *skip* is specified) are not available, it shall not be considered an error; the *od* utility shall format the input that is available.

101297 XSI **−o** Interpret *word*s (two-byte units) in octal. This shall be equivalent to **−t o2**.

101298 XSI **−s** Interpret *word*s (two-byte units) in signed decimal. This shall be equivalent to
101299 **−t d2**.

101300 **−t** *type_string*
101301 Specify one or more output types. See the EXTENDED DESCRIPTION section. The
101302 application shall ensure that the *type_string* option-argument is a string specifying
101303 the types to be used when writing the input data. The string shall consist of the
101304 type specification characters `a`, `c`, `d`, `f`, `o`, `u`, and `x`, specifying named character,
101305 character, signed decimal, floating point, octal, unsigned decimal, and
101306 hexadecimal, respectively. The type specification characters `d`, `f`, `o`, `u`, and `x` can be
101307 followed by an optional unsigned decimal integer that specifies the number of
101308 bytes to be transformed by each instance of the output type. The type specification
101309 character `f` can be followed by an optional `F`, `D`, or `L` indicating that the conversion
101310 should be applied to an item of type **float**, **double**, or **long double**, respectively.
101311 The type specification characters `d`, `o`, `u`, and `x` can be followed by an optional `C`, `S`,
101312 `I`, or `L` indicating that the conversion should be applied to an item of type **char**,
101313 **short**, **int**, or **long**, respectively. Multiple types can be concatenated within the
101314 same *type_string* and multiple **−t** options can be specified. Output lines shall be
101315 written for each type specified in the order in which the type specification
101316 characters are specified.

101317 **−v** Write all input data. Without the **−v** option, any number of groups of output lines,
101318 which would be identical to the immediately preceding group of output lines
101319 (except for the byte offsets), shall be replaced with a line containing only an
101320 <asterisk> (`'*'`).

101321 XSI **−x** Interpret *word*s (two-byte units) in hexadecimal. This shall be equivalent to **−t x2**.

101322 XSI Multiple types can be specified by using multiple **−bcdostx** options. Output lines are written for
101323 each type specified in the order in which the types are specified.

101324 **OPERANDS**

101325 The following operands shall be supported:

101326 *file* A pathname of a file to be read. If no *file* operands are specified, the standard input
101327 shall be used.

101328 If there are no more than two operands, none of the **−A**, **−j**, **−N**, **−t**, or **−v** options is
101329 specified, and either of the following is true: the first character of the last operand
101330 is a <plus-sign> (`'+'`), or there are two operands and the first character of the last
101331 XSI operand is numeric; the last operand shall be interpreted as an offset operand on
101332 XSI-conformant systems. Under these conditions, the results are unspecified on
101333 systems that are not XSI-conformant systems.

101334 XSI **[+]***offset***[.][b]** The *offset* operand specifies the offset in the file where dumping is to commence.
101335 This operand is normally interpreted as octal bytes. If `'.'` is appended, the offset
101336 shall be interpreted in decimal. If `'b'` is appended, the offset shall be interpreted
101337 in units of 512 bytes.

101338 **STDIN**

101339 The standard input shall be used if no *file* operands are specified, and shall be used if a *file*
101340 operand is `'−'` and the implementation treats the `'−'` as meaning standard input. Otherwise,
101341 the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *od*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the locale for selecting the radix character used when writing floating-point formatted output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *od* utility shall copy sequentially each input file to standard output, transforming the input data according to the output types specified by the **−t** option XSI or the **−bcdosx** options. If no output type is specified, the default output shall be as if **−t oS** had been specified.

The number of bytes transformed by the output type specifier `c` may be variable depending on the *LC_CTYPE* category.

The default number of bytes transformed by output type specifiers `d`, `f`, `o`, `u`, and `x` corresponds to the various C-language types as follows. If the *c99* compiler is present on the system, these specifiers shall correspond to the sizes used by default in that compiler. Otherwise, these sizes may vary among systems that conform to POSIX.1-2017.

> For the type specifier characters `d`, `o`, `u`, and `x`, the default number of bytes shall correspond to the size of the underlying implementation's basic integer type. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **char**, **short**, **int**, and **long**. These numbers can also be specified by an application as the characters `'C'`, `'S'`, `'I'`, and `'L'`, respectively. The implementation shall also support the values 1, 2, 4, and 8, even if it provides no C-Language types of those sizes. The

101386 implementation shall support the decimal value corresponding to the C-language type
101387 **long long**. The byte order used when interpreting numeric values is implementation-
101388 defined, but shall correspond to the order in which a constant of the corresponding type is
101389 stored in memory on the system.

101390 For the type specifier character `f`, the default number of bytes shall correspond to the
101391 number of bytes in the underlying implementation's basic double precision floating-point
101392 data type. The implementation shall support values of the optional number of bytes to be
101393 converted corresponding to the number of bytes in the C-language types **float, double**,
101394 and **long double**. These numbers can also be specified by an application as the characters
101395 `'F'`, `'D'`, and `'L'`, respectively.

101396 The type specifier character `a` specifies that bytes shall be interpreted as named characters from
101397 the International Reference Version (IRV) of the ISO/IEC 646:1991 standard. Only the least
101398 significant seven bits of each byte shall be used for this type specification. Bytes with the values
101399 listed in the following table shall be written using the corresponding names for those characters.

101400 **Table 4-13** Named Characters in *od*

101401

Value	Name	Value	Name	Value	Name	Value	Name
101402 \000	**nul**	\001	**soh**	\002	**stx**	\003	**etx**
101403 \004	**eot**	\005	**enq**	\006	**ack**	\007	**bel**
101404 \010	**bs**	\011	**ht**	\012	**lf** or **nl***	\013	**vt**
101405 \014	**ff**	\015	**cr**	\016	**so**	\017	**si**
101406 \020	**dle**	\021	**dc1**	\022	**dc2**	\023	**dc3**
101407 \024	**dc4**	\025	**nak**	\026	**syn**	\027	**etb**
101408 \030	**can**	\031	**em**	\032	**sub**	\033	**esc**
101409 \034	**fs**	\035	**gs**	\036	**rs**	\037	**us**
101410 \040	**sp**	\177	**del**				

101411 **Note:** The `"\012"` value may be written either as **lf** or **nl**.

101412 The type specifier character `c` specifies that bytes shall be interpreted as characters specified by
101413 the current setting of the *LC_CTYPE* locale category. Characters listed in the table in XBD
101414 Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) shall be written as
101415 the corresponding escape sequences, except that <backslash> shall be written as a single
101416 <backslash> and a NUL shall be written as `'\0'`. Other non-printable characters shall be
101417 written as one three-digit octal number for each byte in the character. Printable multi-byte
101418 characters shall be written in the area corresponding to the first byte of the character; the two-
101419 character sequence `"**"` shall be written in the area corresponding to each remaining byte in the
101420 character, as an indication that the character is continued. When either the **–j** *skip* or **–N** *count*
101421 option is specified along with the `c` type specifier, and this results in an attempt to start or finish
101422 in the middle of a multi-byte character, the result is implementation-defined.

101423 The input data shall be manipulated in blocks, where a block is defined as a multiple of the least
101424 common multiple of the number of bytes transformed by the specified output types. If the least
101425 common multiple is greater than 16, the results are unspecified. Each input block shall be
101426 written as transformed by each output type, one per written line, in the order that the output
101427 types were specified. If the input block size is larger than the number of bytes transformed by
101428 the output type, the output type shall sequentially transform the parts of the input block, and
101429 the output from each of the transformations shall be separated by one or more <blank>
101430 characters.

101431 If, as a result of the specification of the **–N** option or end-of-file being reached on the last input
101432 file, input data only partially satisfies an output type, the input shall be extended sufficiently

with null bytes to write the last byte of the input.

Unless −**A n** is specified, the first output line produced for each input block shall be preceded by the input offset, cumulative across input files, of the next byte to be written. The format of the input offset is unspecified; however, it shall not contain any <blank> characters, shall start at the first character of the output line, and shall be followed by one or more <blank> characters. In addition, the offset of the byte following the last byte written shall be written after all the input data has been processed, but shall not be followed by any <blank> characters.

If no −**A** option is specified, the input offset base is unspecified.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

XSI-conformant applications are warned not to use filenames starting with '+' or a first operand starting with a numeric character so that the old functionality can be maintained by implementations, unless they specify one of the −**A**, −**j**, or −**N** options. To guarantee that one of these filenames is always interpreted as a filename, an application could always specify the address base format with the −**A** option.

EXAMPLES

If a file containing 128 bytes with decimal values zero to 127, in increasing order, is supplied as standard input to the command:

```
od −A d −t a
```

on an implementation using an input block size of 16 bytes, the standard output, independent of the current locale setting, would be similar to:

```
0000000 nul soh stx etx eot enq ack bel  bs  ht  nl  vt  ff  cr  so  si
0000016 dle dc1 dc2 dc3 dc4 nak syn etb can  em sub esc  fs  gs  rs  us
0000032  sp   !   "   #   $   %   &   '   (   )   *   +   ,   −   .   /
0000048   0   1   2   3   4   5   6   7   8   9   :   ;   <   =   >   ?
0000064   @   A   B   C   D   E   F   G   H   I   J   K   L   M   N   O
0000080   P   Q   R   S   T   U   V   W   X   Y   Z   [   \   ]   ^   _
0000096   `   a   b   c   d   e   f   g   h   i   j   k   l   m   n   o
0000112   p   q   r   s   t   u   v   w   x   y   z   {   |   }   ~ del
0000128
```

Note that this volume of POSIX.1-2017 allows **nl** or **lf** to be used as the name for the ISO/IEC 646:1991 standard IRV character with decimal value 10. The IRV names this character **lf** (line feed), but traditional implementations have referred to this character as newline (**nl**) and the POSIX locale character set symbolic name for the corresponding character is a <newline>.

The command:

```
od −A o −t o2x2x −N 18
```

on a system with 32-bit words and an implementation using an input block size of 16 bytes could write 18 bytes in approximately the following format:

```
0000000 032056 031440 041123 042040 052516 044530 020043 031464
```

```
                342e   3320   4253   4420   554e   4958   2023   3334
                   342e3320       42534420       554e4958       20233334
0000020 032472
                353a
                   353a0000
0000022
```

The command:

```
od -A d -t f -t o4 -t x4 -N 24 -j 0x15
```

on a system with 64-bit doubles (for example, IEEE Std 754-1985 double precision floating-point format) would skip 21 bytes of input data and then write 24 bytes in approximately the following format:

```
0000000    1.00000000000000e+00    1.57350000000000e+01
          07774000000 00000000000 10013674121 35341217270
             3ff00000    00000000    402f3851    eb851eb8
0000016    1.40668230000000e+02
          10030312542 04370303230
             40619562    23e18698
0000024
```

RATIONALE

The *od* utility went through several names in early proposals, including *hd*, *xd*, and most recently *hexdump*. There were several objections to all of these based on the following reasons:

The *hd* and *xd* names conflicted with historical utilities that behaved differently.

The *hexdump* description was much more complex than needed for a simple dump utility.

The *od* utility has been available on all historical implementations and there was no need to create a new name for a utility so similar to the historical *od* utility.

The original reasons for not standardizing historical *od* were also fairly widespread. Those reasons are given below along with rationale explaining why the standard developers believe that this version does not suffer from the indicated problem:

The BSD and System V versions of *od* have diverged, and the intersection of features provided by both does not meet the needs of the user community. In fact, the System V version only provides a mechanism for dumping octal bytes and **short**s, signed and unsigned decimal **short**s, hexadecimal **short**s, and ASCII characters. BSD added the ability to dump **float**s, **double**s, named ASCII characters, and octal, signed decimal, unsigned decimal, and hexadecimal **long**s. The version presented here provides more normalized forms for dumping bytes, **short**s, **int**s, and **long**s in octal, signed decimal, unsigned decimal, and hexadecimal; **float**, **double**, and **long double**; and named ASCII as well as current locale characters.

It would not be possible to come up with a compatible superset of the BSD and System V flags that met the requirements of the standard developers. The historical default *od* output is the specified default output of this utility. None of the option letters chosen for this version of *od* conflict with any of the options to historical versions of *od*.

On systems with different sizes for **short**, **int**, and **long**, there was no way to ask for dumps of **int**s, even in the BSD version. Because of the way options are named, the name space could not be extended to solve these problems. This is why the **−t** option was added (with type specifiers more closely matched to the *printf*( ) formats used in the rest of this volume of POSIX.1-2017) and the optional field sizes were added to the `d`, `f`, `o`, `u`, and `x` type

specifiers. It is also one of the reasons why the historical practice was not mandated as a required obsolescent form of *od*. (Although the old versions of *od* are not listed as an obsolescent form, implementations are urged to continue to recognize the older forms for several more years.) The `a`, `c`, `f`, `o`, and `x` types match the meaning of the corresponding format characters in the historical implementations of *od* except for the default sizes of the fields converted. The `d` format is signed in this volume of POSIX.1-2017 to match the *printf*( ) notation. (Historical versions of *od* used `d` as a synonym for `u` in this version. The System V implementation uses `s` for signed decimal; BSD uses `i` for signed decimal and `s` for null-terminated strings.) Other than `d` and `u`, all of the type specifiers match format characters in the historical BSD version of **od**.

The sizes of the C-language types **char**, **short**, **int**, **long**, **float**, **double**, and **long double** are used even though it is recognized that there may be zero or more than one compiler for the C language on an implementation and that they may use different sizes for some of these types. (For example, one compiler might use 2 bytes **short**s, 2 bytes **int**s, and 4 bytes **long**s, while another compiler (or an option to the same compiler) uses 2 bytes **short**s, 4 bytes **int**s, and 4 bytes **long**s.) Nonetheless, there has to be a basic size known by the implementation for these types, corresponding to the values reported by invocations of the *getconf* utility when called with *system_var* operands {UCHAR_MAX}, {USHORT_MAX}, {UINT_MAX}, and {ULONG_MAX} for the types **char**, **short**, **int**, and **long**, respectively. There are similar constants required by the ISO C standard, but not required by the System Interfaces volume of POSIX.1-2017 or this volume of POSIX.1-2017. They are {FLT_MANT_DIG}, {DBL_MANT_DIG}, and {LDBL_MANT_DIG} for the types **float**, **double**, and **long double**, respectively. If the optional *c99* utility is provided by the implementation and used as specified by this volume of POSIX.1-2017, these are the sizes that would be provided. If an option is used that specifies different sizes for these types, there is no guarantee that the *od* utility is able to interpret binary data output by such a program correctly.

This volume of POSIX.1-2017 requires that the numeric values of these lengths be recognized by the *od* utility and that symbolic forms also be recognized. Thus, a conforming application can always look at an array of **unsigned long** data elements using *od* **−t** *uL*.

The method of specifying the format for the address field based on specifying a starting offset in a file unnecessarily tied the two together. The **−A** option now specifies the address base and the **−S** option specifies a starting offset.

It would be difficult to break the dependence on US ASCII to achieve an internationalized utility. It does not seem to be any harder for *od* to dump characters in the current locale than it is for the *ed* or *sed* **l** commands. The `c` type specifier does this without difficulty and is completely compatible with the historical implementations of the **c** format character when the current locale uses a superset of the ISO/IEC 646: 1991 standard as a codeset. The `a` type specifier (from the BSD **a** format character) was left as a portable means to dump ASCII (or more correctly ISO/IEC 646: 1991 standard (IRV)) so that headers produced by *pax* could be deciphered even on systems that do not use the ISO/IEC 646: 1991 standard as a subset of their base codeset.

The use of `"**"` as an indication of continuation of a multi-byte character in `c` specifier output was chosen based on seeing an implementation that uses this method. The continuation bytes have to be marked in a way that is not ambiguous with another single-byte or multi-byte character.

An early proposal used **−S** and **−n**, respectively, for the **−j** and **−N** options eventually selected. These were changed to avoid conflicts with historical implementations.

The original standard specified **−t o2** as the default when no output type was given. This was changed to **−t oS** (the length of a **short**) to accommodate a supercomputer implementation that historically used 64 bits as its default (and that defined shorts as 64 bits). This change should not affect conforming applications. The requirement to support lengths of 1, 2, and 4 was added at the same time to address an historical implementation that had no two-byte data types in its C compiler.

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

All option and operand interfaces marked XSI may be removed in a future version.

XBD Chapter 5 (on page 121), Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the description of the **−c** option, the phrase ``This is equivalent to **−t c**.'' is deleted.

The FUTURE DIRECTIONS section is modified.

Issue 6

The *od* utility is changed to remove the assumption that **short** was a two-byte entity, as per the revisions in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/33 is applied, correcting the examples which used an undefined **−n** option, which should have been **−N**.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/19 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-37 is applied, updating the OPERANDS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

paste — merge corresponding or subsequent lines of files

SYNOPSIS

```
paste [−s] [−d list] file...
```

DESCRIPTION

The *paste* utility shall concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.

The default operation of *paste* shall concatenate the corresponding lines of the input files. The <newline> of every line except the line from the last input file shall be replaced with a <tab>.

If an end-of-file condition is detected on one or more input files, but not all input files, *paste* shall behave as though empty lines were read from the files on which end-of-file was detected, unless the **−s** option is specified.

OPTIONS

The *paste* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−d *list* Unless a <backslash> character appears in *list*, each character in *list* is an element specifying a delimiter character. If a <backslash> character appears in *list*, the <backslash> character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <tab>, to replace the <newline> of the input lines. The elements in *list* shall be used circularly; that is, when the list is exhausted the first element from the list is reused. When the **−s** option is specified:

> The last <newline> in a file shall not be modified.
>
> The delimiter shall be reset to the first element of *list* after each *file* operand is processed.

When the **−s** option is not specified:

> The <newline> characters in the file specified by the last *file* operand shall not be modified.
>
> The delimiter shall be reset to the first element of list each time a line is processed from each file.

If a <backslash> character appears in *list*, it and the character following it shall be used to represent the following delimiter characters:

`\n` <newline>.

`\t` <tab>.

`\\` <backslash> character.

`\0` Empty string (not a null character). If `'\0'` is immediately followed by the character `'x'`, the character `'X'`, or any character defined by the *LC_CTYPE* **digit** keyword (see XBD Chapter 7, on page 135), the results are unspecified.

If any other characters follow the <backslash>, the results are unspecified.

−s Concatenate all of the lines from each input file into one line of output per file, in command line order. The <newline> of every line except the last line in each input file shall be replaced with a <tab>, unless otherwise specified by the **−d** option. If an input file is empty, the output line corresponding to that file shall consist of

only a <newline> character.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If `'-'` is specified for one or more of the *file*s, the standard input shall be used; the standard input shall be read one line at a time, circularly, for each instance of `'-'`. Implementations shall support pasting of at least 12 *file* operands.

STDIN

The standard input shall be used only if one or more *file* operands is `'-'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *paste*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Concatenated lines of input files shall be separated by the <tab> (or other characters under the control of the **–d** option) and terminated by a <newline>.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If one or more input files cannot be opened when the **−s** option is not specified, a diagnostic message shall be written to standard error, but no output is written to standard output. If the **−s** option is specified, the *paste* utility shall provide the default behavior described in Section 1.4 (on page 2336).

APPLICATION USAGE

When the escape sequences of the *list* option-argument are used in a shell script, they must be quoted; otherwise, the shell treats the <backslash> as a special character.

Conforming applications should only use the specific <backslash>-escaped delimiters presented in this volume of POSIX.1-2017. Historical implementations treat `'\x'`, where `'x'` is not in this list, as `'x'`, but future implementations are free to expand this list to recognize other common escapes similar to those accepted by *printf* and other standard utilities.

Most of the standard utilities work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if *file* contains long lines:

```
cut −b 1−500 −n file > file1
cut −b 501− −n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline>) and **file2** that contains the remainder of the data from *file*. Note that **file2** is not a text file if there are lines in *file* that are longer than 500 + {LINE_MAX} bytes. The original file can be recreated from **file1** and **file2** using the command:

```
paste −d "\0" file1 file2 > file
```

The commands:

```
paste −d "\0" ...
paste −d "" ...
```

are not necessarily equivalent; the latter is not specified by this volume of POSIX.1-2017 and may result in an error. The construct `'\0'` is used to mean ``no separator'' because historical versions of *paste* did not follow the syntax guidelines, and the command:

```
paste −d"" ...
```

could not be handled properly by *getopt*( ).

EXAMPLES

1. Write out a directory in four columns:

   ```
   ls | paste − − − −
   ```

2. Combine pairs of lines from a file into single lines:

   ```
   paste −s −d "\t\n" file
   ```

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

patch ‡'apply changes to files

SYNOPSIS

```
patch [−blNR] [−c|−e|−n|−u] [−d dir] [−D define] [−i patchfile]
    [−o outfile] [−p num] [−r rejectfile] [file]
```

DESCRIPTION

The *patch* utility shall read a source (patch) file containing any of four forms of difference (diff) listings produced by the *diff* utility (normal, copied context, unified context, or in the style of *ed*) and apply those differences to a file. By default, *patch* shall read from the standard input.

The *patch* utility shall attempt to determine the type of the *diff* listing, unless overruled by a **−c**, **−e**, **−n**, or **−u** option.

If the patch file contains more than one patch, *patch* shall attempt to apply each of them as if they came from separate patch files. (In this case, the application shall ensure that the name of the patch file is determinable for each *diff* listing.)

OPTIONS

The *patch* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−b Save a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix **.orig** appended to it. If the file already exists, it shall be overwritten; if multiple patches are applied to the same file, the **.orig** file shall be written only for the first patch. When the **−o** *outfile* option is also specified, *file***.orig** shall not be created but, if *outfile* already exists, *outfile***.orig** shall be created.

−c Interpret the patch file as a copied context difference (the output of the utility *diff* when the **−c** or **−C** options are specified).

−d *dir* Change the current directory to *dir* before processing as described in the EXTENDED DESCRIPTION section.

−D *define* Mark changes with one of the following C preprocessor constructs:

```
#ifdef define
...
#endif
```

```
#ifndef define
...
#endif
```

optionally combined with the C preprocessor construct **#else**. If the patched file is processed with the C preprocessor, where the macro *define* is defined, the output shall contain the changes from the patch file; otherwise, the output shall not contain the patches specified in the patch file.

−e Interpret the patch file as an *ed* script, rather than a *diff* script.

−i *patchfile* Read the patch information from the file named by the pathname *patchfile*, rather than the standard input.

−l (The letter ell.) Cause any sequence of <blank> characters in the difference script to match any sequence of <blank> characters in the input file. Other characters shall be matched exactly.

101781 **−n** Interpret the script as a normal difference.

101782 **−N** Ignore patches where the differences have already been applied to the file; by
101783 default, already-applied patches shall be rejected.

101784 **−o** *outfile* Instead of modifying the files (specified by the *file* operand or the difference
101785 listings) directly, write a copy of the file referenced by each patch, with the
101786 appropriate differences applied, to *outfile*. Multiple patches for a single file shall be
101787 applied to the intermediate versions of the file created by any previous patches,
101788 and shall result in multiple, concatenated versions of the file being written to
101789 *outfile*.

101790 **−p** *num* For all pathnames in the patch file that indicate the names of files to be patched,
101791 delete *num* pathname components from the beginning of each pathname. If the
101792 pathname in the patch file is absolute, any leading <slash> characters shall be
101793 considered the first component (that is, **−p 1** shall remove the leading <slash>
101794 characters). Specifying **−p 0** shall cause the full pathname to be used. If **−p** is not
101795 specified, only the basename (the final pathname component) shall be used.

101796 **−R** Reverse the sense of the patch script; that is, assume that the difference script was
101797 created from the new version to the old version. The **−R** option cannot be used
101798 with *ed* scripts. The *patch* utility shall attempt to reverse each portion of the script
101799 before applying it. Rejected differences shall be saved in swapped format. If this
101800 option is not specified, and until a portion of the patch file is successfully applied,
101801 *patch* attempts to apply each portion in its reversed sense as well as in its normal
101802 sense. If the attempt is successful, the user shall be prompted to determine whether
101803 the **−R** option should be set.

101804 **−r** *rejectfile* Override the default reject filename. In the default case, the reject file shall have the
101805 same name as the output file, with the suffix **.rej** appended to it; see Patch
101806 Application (on page 3059).

101807 **−u** Interpret the patch file as a unified context difference (the output of the *diff* utility
101808 when the **−u** or **−U** options are specified).

101809 **OPERANDS**

101810 The following operand shall be supported:

101811 *file* A pathname of a file to patch.

101812 **STDIN**

101813 See the INPUT FILES section.

101814 **INPUT FILES**

101815 Input files shall be text files.

101816 **ENVIRONMENT VARIABLES**

101817 The following environment variables shall affect the execution of *patch*:

101818 *LANG* Provide a default value for the internationalization variables that are unset or null.
101819 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
101820 used to determine the values of locale categories.)

101821 *LC_ALL* If set to a non-empty string value, override the values of all the other
101822 internationalization variables.

101823 *LC_COLLATE*
101824 Determine the locale for the behavior of ranges, equivalence classes, and multi-
101825 character collating elements used in the extended regular expression defined for

101826 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

101827 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
101828 characters (for example, single-byte as opposed to multi-byte characters in
101829 arguments and input files), and the behavior of character classes used in the
101830 extended regular expression defined for the **yesexpr** locale keyword in the
101831 *LC_MESSAGES* category.

101832 *LC_MESSAGES*
101833 Determine the locale used to process affirmative responses, and the locale used to
101834 affect the format and contents of diagnostic messages and prompts written to
101835 standard error.

101836 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

101837 *LC_TIME* Determine the locale for recognizing the format of file timestamps written by the
101838 *diff* utility in a context-difference input file.

101839 **ASYNCHRONOUS EVENTS**
101840 Default.

101841 **STDOUT**
101842 Not used.

101843 **STDERR**
101844 The standard error shall be used for diagnostic and informational messages.

101845 **OUTPUT FILES**
101846 The output of the *patch* utility, the save files (**.orig** suffixes), and the reject files (**.rej** suffixes) shall
101847 be text files.

101848 **EXTENDED DESCRIPTION**
101849 A patch file may contain patching instructions for more than one file; filenames shall be
101850 determined as specified in Filename Determination (on page 3059). When the **−b** option is
101851 specified, for each patched file, the original shall be saved in a file of the same name with the
101852 suffix **.orig** appended to it.

101853 For each patched file, a reject file may also be created as noted in Patch Application (on page
101854 3059). In the absence of a **−r** option, the name of this file shall be formed by appending the suffix
101855 **.rej** to the original filename.

101856 **Patch File Format**

101857 The patch file shall contain zero or more lines of header information followed by one or more
101858 patches. Each patch shall contain zero or more lines of filename identification in the format
101859 produced by the **−c**, **−C**, **−u**, or **−U** options of the *diff* utility, and one or more sets of *diff* output,
101860 which are customarily called *hunks*.

101861 The *patch* utility shall recognize the following expression in the header information:

101862 **Index:** *pathname*
101863 The file to be patched is named *pathname*.

101864 If all lines (including headers) within a patch begin with the same leading sequence of <blank>
101865 characters, the *patch* utility shall remove this sequence before proceeding. Within each patch, if
101866 the type of difference is common context, the *patch* utility shall recognize the following
101867 expressions:

101868 *** *filename timestamp*
101869 The patches arose from *filename*.

101870 −−− *filename timestamp*
101871 The patches should be applied to *filename*.

101872 If the type of difference is unified context, the *patch* utility shall recognize the following
101873 expressions:

101874 −−− *filename timestamp*
101875 The patches arose from *filename*.

101876 +++ *filename timestamp*
101877 The patches should be applied to *filename*.

101878 Each hunk within a patch shall be the *diff* output to change a line range within the original file.
101879 The line numbers for successive hunks within a patch shall occur in ascending order.

101880 **Filename Determination**

101881 If no *file* operand is specified, *patch* shall perform the following steps to determine the filename
101882 to use:

101883 1. If the type of *diff* is context, the *patch* utility shall delete pathname components (as
101884 specified by the −**p** option) from the filename on the line beginning with `"***"` (if copied
101885 context) or `"---"` (if unified context), then test for the existence of this file relative to the
101886 current directory (or the directory specified with the −**d** option). If the file exists, the *patch*
101887 utility shall use this filename.

101888 2. If the type of *diff* is context, the *patch* utility shall delete the pathname components (as
101889 specified by the −**p** option) from the filename on the line beginning with `"---"` (if copied
101890 context) or `"+++"` (if unified context), then test for the existence of this file relative to the
101891 current directory (or the directory specified with the −**d** option). If the file exists, the *patch*
101892 utility shall use this filename.

101893 3. If the header information contains a line beginning with the string **Index:**, the *patch* utility
101894 shall delete pathname components (as specified by the −**p** option) from this line, then test
101895 for the existence of this file relative to the current directory (or the directory specified
101896 with the −**d** option). If the file exists, the *patch* utility shall use this filename.

101897 XSI 4. If an **SCCS** directory exists in the current directory, *patch* shall attempt to perform a *get* −**e**
101898 **SCCS/s.***filename* command to retrieve an editable version of the file. If the file exists, the
101899 *patch* utility shall use this filename.

101900 5. The *patch* utility shall write a prompt to standard output and request a filename
101901 interactively from the controlling terminal (for example, **/dev/tty**).

101902 **Patch Application**

101903 If the −**c**, −**e**, −**n**, or −**u** option is present, the *patch* utility shall interpret information within each
101904 hunk as a copied context difference, an *ed* difference, a normal difference, or a unified context
101905 difference, respectively. In the absence of any of these options, the *patch* utility shall determine
101906 the type of difference based on the format of information within the hunk.

101907 For each hunk, the *patch* utility shall begin to search for the place to apply the patch at the line
101908 number at the beginning of the hunk, plus or minus any offset used in applying the previous
101909 hunk. If lines matching the hunk context are not found, *patch* shall scan both forwards and
101910 backwards at least 1 000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan shall take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context shall be ignored and another scan shall be made. Implementations may search more extensively for installation locations.

If no location can be found, the *patch* utility shall append the hunk to the reject file. A rejected hunk that is a copied context difference, an *ed* difference, or a normal difference shall be written in copied-context-difference format regardless of the format of the patch file. It is implementation-defined whether a rejected hunk that is a unified context difference is written in copied-context-difference format or in unified-context-difference format. If the input was a normal or *ed*-style difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they shall reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an *ed* diff, the implementation may accomplish the patching by invoking the *ed* utility.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

1 One or more lines were written to a reject file.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Patches that cannot be correctly placed in the file shall be written to a reject file.

APPLICATION USAGE

The **−R** option does not work with *ed* scripts because there is too little information to reconstruct the reverse operation.

The **−p** option makes it possible to customize a patch file to local user directory structures without manually editing the patch file. For example, if the filename in the patch file was:

```
/curds/whey/src/blurfl/blurfl.c
```

Setting **−p 0** gives the entire pathname unmodified; **−p 1** gives:

```
curds/whey/src/blurfl/blurfl.c
```

without the leading <slash>, **−p 4** gives:

```
blurfl/blurfl.c
```

and not specifying **−p** at all gives:

```
blurfl.c .
```

EXAMPLES

None.

RATIONALE

Some of the functionality in historical *patch* implementations was not specified. The following documents those features present in historical implementations that have not been specified.

A deleted piece of functionality was the `'+'` pseudo-option allowing an additional set of options and a patch file operand to be given. This was seen as being insufficiently useful to standardize.

In historical implementations, if the string `"Prereq:"` appeared in the header, the *patch* utility

101953 would search for the corresponding version information (the string specified in the header,
101954 delimited by <blank> characters or the beginning or end of a line or the file) anywhere in the
101955 original file. This was deleted as too simplistic and insufficiently trustworthy a mechanism to
101956 standardize. For example, if:

101957 `Prereq: 1.2`

101958 were in the header, the presence of a delimited 1.2 anywhere in the file would satisfy the
101959 prerequisite.

101960 The following options were dropped from historical implementations of *patch* as insufficiently
101961 useful to standardize:

101962 **−b** The **−b** option historically provided a method for changing the name extension of
101963 the backup file from the default **.orig**. This option has been modified and retained
101964 in this volume of POSIX.1-2017.

101965 **−F** The **−F** option specified the number of lines of a context diff to ignore when
101966 searching for a place to install a patch.

101967 **−f** The **−f** option historically caused *patch* not to request additional information from
101968 the user.

101969 **−r** The **−r** option historically provided a method of overriding the extension of the
101970 reject file from the default **.rej**.

101971 **−s** The **−s** option historically caused *patch* to work silently unless an error occurred.

101972 **−x** The **−x** option historically set internal debugging flags.

101973 In some file system implementations, the saving of a **.orig** file may produce unwanted results. In
101974 the case of 12, 13, or 14-character filenames (on file systems supporting 14-character maximum
101975 filenames), the **.orig** file overwrites the new file. The reject file may also exceed this filename
101976 limit. It was suggested, due to some historical practice, that a <tilde> (`'~'`) suffix be used
101977 instead of **.orig** and some other character instead of the **.rej** suffix. This was rejected because it is
101978 not obvious to the user which file is which. The suffixes **.orig** and **.rej** are clearer and more
101979 understandable.

101980 The **−b** option has the opposite sense in some historical implementations ‡ĺdo not save the**orig**
101981 file. The default case here is not to save the files, making *patch* behave more consistently with the
101982 other standard utilities.

101983 The **−w** option in early proposals was changed to **−l** to match historical practice.

101984 The **−N** option was included because without it, a non-interactive application cannot reject
101985 previously applied patches. For example, if a user is piping the output of *diff* into the *patch*
101986 utility, and the user only wants to patch a file to a newer version non-interactively, the **−N** option
101987 is required.

101988 Changes to the **−l** option description were proposed to allow matching across <newline>
101989 characters in addition to just <blank> characters. Since this is not historical practice, and since
101990 some ambiguities could result, it is suggested that future developments in this area utilize
101991 another option letter, such as **−L**.

101992 The **−u** option of GNU *patch* has been added, along with support for unified context formats.

FUTURE DIRECTIONS

None.

SEE ALSO

diff, *ed*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The description of the **−D** option and the steps in Filename Determination (on page 3059) are changed to match historical practice as defined in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/34 is applied, clarifying the way that the *patch* utility performs **ifdef** selection for the **−D** option.

Issue 7

The *patch* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-103 and SD5-XCU-ERN-120 are applied, adding the **−u** option.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* and *LC_CTYPE* environment variables and adding the *LC_COLLATE* environment variable.

NAME

pathchk ‡'check pathnames

SYNOPSIS

```
pathchk [−p] [−P] pathname...
```

DESCRIPTION

The *pathchk* utility shall check that one or more pathnames are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation results). More extensive portability checks are provided by the **−p** and **−P** options.

By default, the *pathchk* utility shall check each component of each *pathname* operand based on the underlying file system. A diagnostic shall be written for each *pathname* operand that:

Is longer than {PATH_MAX} bytes (see **Pathname Variable Values** in XBD **<limits.h>**)

Contains any component longer than {NAME_MAX} bytes in its containing directory

Contains any component in a directory that is not searchable

Contains any byte sequence that is not valid in its containing directory

The format of the diagnostic message is not specified, but shall indicate the error detected and the corresponding *pathname* operand.

It shall not be considered an error if one or more components of a *pathname* operand do not exist as long as a file matching the pathname specified by the missing components could be created that does not violate any of the checks specified above.

OPTIONS

The *pathchk* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−p Instead of performing checks based on the underlying file system, write a diagnostic for each *pathname* operand that:

Is longer than {_POSIX_PATH_MAX} bytes (see **Minimum Values** in XBD **<limits.h>**)

Contains any component longer than {_POSIX_NAME_MAX} bytes

Contains any character in any component that is not in the portable filename character set

−P Write a diagnostic for each *pathname* operand that:

Contains a component whose first character is the <hyphen-minus> character

Is empty

OPERANDS

The following operand shall be supported:

pathname A pathname to be checked.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pathchk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All *pathname* operands passed all of the checks.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *test* utility can be used to determine whether a given pathname names an existing file; it does not, however, give any indication of whether or not any component of the pathname was truncated in a directory where the _POSIX_NO_TRUNC feature is not in effect. The *pathchk* utility does not check for file existence; it performs checks to determine whether a pathname does exist or could be created with no pathname component truncation.

The *noclobber* option in the shell (see the *set* special built-in) can be used to atomically create a file. As with all file creation semantics in the System Interfaces volume of POSIX.1-2017, it guarantees atomic creation, but still depends on applications to agree on conventions and cooperate on the use of files after they have been created.

To verify that a pathname meets the requirements of filename portability, applications should

use both the **−p** and **−P** options together.

EXAMPLES

To verify that all pathnames in an imported data interchange archive are legitimate and unambiguous on the current system:

```
# This example assumes that no pathnames in the archive
# contain <newline> characters.
pax −f archive | sed −e 's/[^[:alnum:]]/\\&/g' | xargs pathchk −−
if [ $? −eq 0 ]
then
    pax −r −f archive
else
    echo Investigate problems before importing files.
    exit 1
fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the System Interfaces volume of POSIX.1-2017 that also supports the *pax* utility:

```
find . −exec pathchk −p −P {} +
if [ $? −eq 0 ]
then
    pax −w −f ../archive .
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied pathname names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```
case $− in
    *C*)    reset="";;
    *)      reset="set +C"
            set −C;;
esac
test −r "$path" && pathchk "$path.out" &&
    rm "$path.out" > "$path.out"
if [ $? −ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset    # Reset the noclobber option in case a trap
              # on EXIT depends on it.
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. **PROCESSING** represents the code that is used by the application to use **$path** once it is verified that **$path.out** works as intended.

2. The state of the *noclobber* option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The **reset** variable is used in this example to restore the initial state.)

3. Note the usage of:

```
rm "$path.out" > "$path.out"
```

   a. The *pathchk* command has already verified, at this point, that **$path.out** is not truncated.

   b. With the *noclobber* option set, the shell verifies that **$path.out** does not already exist before invoking *rm*.

   c. If the shell succeeded in creating **$path.out**, *rm* removes it so that the application can create the file again in the **PROCESSING** step.

   d. If the **PROCESSING** step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

      should be replaced with:

```
> "$path.out"
```

      which verifies that the file did not already exist, but leaves **$path.out** in place for use by **PROCESSING**.

RATIONALE

The *pathchk* utility was new for the ISO POSIX-2: 1993 standard. It, along with the *set* −**C**(*noclobber*) option added to the shell, replaces the *mktemp*, *validfnam*, and *create* utilities that appeared in early proposals. All of these utilities were attempts to solve several common problems:

> Verify the validity (for several different definitions of ``valid'') of a pathname supplied by a user, generated by an application, or imported from an external source.
>
> Atomically create a file.
>
> Perform various string handling functions to generate a temporary filename.

The *create* utility, included in an early proposal, provided checking and atomic creation in a single invocation of the utility; these are orthogonal issues and need not be grouped into a single utility. Note that the *noclobber* option also provides a way of creating a lock for process synchronization; since it provides an atomic *create*, there is no race between a test for existence and the following creation if it did not exist.

Having a function like *tmpnam*() in the ISO C standard is important in many high-level languages. The shell programming language, however, has built-in string manipulation facilities, making it very easy to construct temporary filenames. The names needed obviously depend on the application, but are frequently of a form similar to:

$TMPDIR/***application_abbreviation***$$.*suffix*

In cases where there is likely to be contention for a given suffix, a simple shell **for** or **while** loop can be used with the shell *noclobber* option to create a file without risk of collisions, as long as applications trying to use the same filename name space are cooperating on the use of files after they have been created.

For historical purposes, −**p** does not check for the use of the <hyphen-minus> character as the first character in a component of the pathname, or for an empty *pathname* operand.

FUTURE DIRECTIONS

None.

NAME

pax — portable archive interchange

SYNOPSIS

```
pax [−dv] [−c|−n] [−H|−L] [−o options] [−f archive] [−s replstr]...
    [pattern...]

pax −r[−c|−n] [−dikuv] [−H|−L] [−f archive] [−o options]... [−p string]...
    [−s replstr]... [pattern...]

pax −w [−dituvX] [−H|−L] [−b blocksize] [[−a] [−f archive]] [−o options]...
    [−s replstr]... [−x format] [file...]

pax −r −w [−diklntuvX] [−H|−L] [−o options]... [−p string]...
    [−s replstr]... [file...] directory
```

DESCRIPTION

The *pax* utility shall read, write, and write lists of the members of archive files and copy directory hierarchies. A variety of archive formats shall be supported; see the **−x** *format* option.

The action to be taken depends on the presence of the **−r** and **−w** options. The four combinations of **−r** and **−w** are referred to as the four modes of operation: **list**, **read**, **write**, and **copy** modes, corresponding respectively to the four forms shown in the SYNOPSIS section.

list In **list** mode (when neither **−r** nor **−w** are specified), *pax* shall write the names of the members of the archive file read from the standard input, with pathnames matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file shall be listed as well.

read In **read** mode (when **−r** is specified, but **−w** is not), *pax* shall extract the members of the archive file read from the standard input, with pathnames matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file shall be extracted as well. The extracted files shall be created performing pathname resolution with the directory in which *pax* was invoked as the current working directory.

If an attempt is made to extract a directory when the directory already exists, this shall not be considered an error. If an attempt is made to extract a FIFO when the FIFO already exists, this shall not be considered an error.

The ownership, access, and modification times, and file mode of the restored files are discussed under the **−p** option.

write In **write** mode (when **−w** is specified, but **−r** is not), *pax* shall write the contents of the *file* operands to the standard output in an archive format. If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input and each entry in this list shall be processed as if it had been a *file* operand on the command line. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

copy In **copy** mode (when both **−r** and **−w** are specified), *pax* shall copy the *file* operands to the destination directory.

If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

The effect of the **copy** shall be as if the copied files were written to a *pax* format archive file and then subsequently extracted, except that copying of sockets may be

supported even if archiving them in write mode is not supported, and that there may be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. If the destination directory is a file of a type not defined by the System Interfaces volume of POSIX.1-2017, the results are implementation-defined; otherwise, it shall be an error for the file named by the *directory* operand not to exist, not be writable by the user, or not be a file of type directory.

In **read** or **copy** modes, if intermediate directories are necessary to extract an archive member, *pax* shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of POSIX.1-2017, called with the following arguments:

The intermediate directory used as the *path* argument

The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO as the *mode* argument

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, *pax* shall write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The archive formats described in the EXTENDED DESCRIPTION section shall be automatically detected on input. The default output archive format shall be implementation-defined.

A single archive can span multiple files. The *pax* utility shall determine, in an implementation-defined manner, what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it shall be an error if these files cannot be linked when the archive is extracted. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this *pax* session, either the data shall be restored from the original file, or a diagnostic message shall be displayed with the name of a file that can be used to extract the data. In traversing directories, *pax* shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, *pax* shall write a diagnostic message to standard error and shall terminate.

OPTIONS

The *pax* utility shall conform to XBD Section 12.2 (on page 216), except that the order of presentation of the **−o**, **−p**, and **−s** options is significant.

The following options shall be supported:

−r Read an archive file from standard input.

−w Write files to the standard output in the specified archive format.

−a Append files to the end of the archive. It is implementation-defined which devices on the system support appending. Additional file formats unspecified by this volume of POSIX.1-2017 may impose restrictions on appending.

−b *blocksize* Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking shall be automatically determined on input. Conforming applications shall not specify a *blocksize* value larger than 32 256. Default blocking when creating archives depends on the archive format. (See the **−x** option below.)

−c Match all file or archive members except those specified by the *pattern* or *file* operands.

102287 **−d** Cause files of type directory being copied or archived or archive members of type
102288 directory being extracted or listed to match only the file or archive member itself
102289 and not the file hierarchy rooted at the file.

102290 **−f** *archive* Specify the pathname of the input or output archive, overriding the default
102291 standard input (in **list** or **read** modes) or standard output (**write** mode).

102292 **−H** If a symbolic link referencing a file of type directory is specified on the command
102293 line, *pax* shall archive the file hierarchy rooted in the file referenced by the link,
102294 using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic
102295 link referencing a file of any other file type which *pax* can normally archive is
102296 specified on the command line, then *pax* shall archive the file referenced by the
102297 link, using the name of the link. The default behavior, when neither **−H** or **−L** are
102298 specified, shall be to archive the symbolic link itself.

102299 **−i** Interactively rename files or archive members. For each archive member matching
102300 a *pattern* operand or file matching a *file* operand, a prompt shall be written to the
102301 file **/dev/tty**. The prompt shall contain the name of the file or archive member, but
102302 the format is otherwise unspecified. A line shall then be read from **/dev/tty**. If this
102303 line is blank, the file or archive member shall be skipped. If this line consists of a
102304 single period, the file or archive member shall be processed with no modification
102305 to its name. Otherwise, its name shall be replaced with the contents of the line. The
102306 *pax* utility shall immediately exit with a non-zero exit status if end-of-file is
102307 encountered when reading a response or if **/dev/tty** cannot be opened for reading
102308 and writing.

102309 The results of extracting a hard link to a file that has been renamed during
102310 extraction are unspecified.

102311 **−k** Prevent the overwriting of existing files.

102312 **−l** (The letter ell.) In **copy** mode, hard links shall be made between the source and
102313 destination file hierarchies whenever possible. If specified in conjunction with **−H**
102314 or **−L**, when a symbolic link is encountered, the hard link created in the destination
102315 file hierarchy shall be to the file referenced by the symbolic link. If specified when
102316 neither **−H** nor **−L** is specified, when a symbolic link is encountered, the
102317 implementation shall create a hard link to the symbolic link in the source file
102318 hierarchy or copy the symbolic link to the destination.

102319 **−L** If a symbolic link referencing a file of type directory is specified on the command
102320 line or encountered during the traversal of a file hierarchy, *pax* shall archive the file
102321 hierarchy rooted in the file referenced by the link, using the name of the link as the
102322 root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any
102323 other file type which *pax* can normally archive is specified on the command line or
102324 encountered during the traversal of a file hierarchy, *pax* shall archive the file
102325 referenced by the link, using the name of the link. The default behavior, when
102326 neither **−H** or **−L** are specified, shall be to archive the symbolic link itself.

102327 **−n** Select the first archive member that matches each *pattern* operand. No more than
102328 one archive member shall be matched for each pattern (although members of type
102329 directory shall still match the file hierarchy rooted at that file).

102330 **−o** *options* Provide information to the implementation to modify the algorithm for extracting
102331 or writing files. The value of *options* shall consist of one or more
102332 <comma>-separated keywords of the form:

102333 *keyword*`[[:]`=*value*`][,`*keyword*`[[:]`=*value*`], ...]`

Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed produces undefined results.

Keywords in the *options* argument shall be a string that would be a valid portable filename as described in XBD Section 3.282 (on page 79).

Note: Keywords are not expected to be filenames, merely to follow the same character composition rules as portable filenames.

Keywords can be preceded with white space. The *value* field shall consist of zero or more characters; within *value*, the application shall precede any literal <comma> with a <backslash>, which shall be ignored, but preserves the <comma> as part of *value*. A <comma> as the final character, or a <comma> followed solely by white space as the final characters, in *options* shall be ignored. Multiple **−o** options can be specified; if keywords given to these multiple **−o** options conflict, the keywords and values appearing later in command line sequence shall take precedence and the earlier shall be silently ignored. The following keyword values of *options* shall be supported for the file formats as indicated:

delete=*pattern*
(Applicable only to the **−x pax** format.) When used in **write** or **copy** mode, *pax* shall omit from extended header records that it produces any keywords matching the string pattern. When used in **read** or **list** mode, *pax* shall ignore any keywords matching the string pattern in the extended header records. In both cases, matching shall be performed using the pattern matching notation described in Section 2.13.1 (on page 2382) and Section 2.13.2 (on page 2383). For example:

```
−o delete=security.*
```

would suppress security-related information. See pax Extended Header (on page 3082) for extended header record keyword usage.

When multiple **−odelete=pattern** options are specified, the patterns shall be additive; all keywords matching the specified string patterns shall be omitted from extended header records that *pax* produces.

exthdr.name=*string*
(Applicable only to the **−x pax** format.) This keyword allows user control over the name that is written into the **ustar** header blocks for the extended header produced under the circumstances described in pax Header Block (on page 3081). The name shall be the contents of *string*, after the following character substitutions have been made:

string **Includes:**	**Replaced by:**
`%d`	The directory name of the file, equivalent to the result of the *dirname* utility on the translated pathname.
`%f`	The filename of the file, equivalent to the result of the *basename* utility on the translated pathname.
`%p`	The process ID of the *pax* process.
`%%`	A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no **−o exthdr.name=string** is specified, *pax* shall use the following default

102380 value:

102381 `%d/PaxHeaders.%p/%f`

102382 **globexthdr.name**=*string*

102383 (Applicable only to the −**x pax** format.) When used in **write** or **copy** mode
102384 with the appropriate options, *pax* shall create global extended header records
102385 with **ustar** header blocks that will be treated as regular files by previous
102386 versions of *pax*. This keyword allows user control over the name that is
102387 written into the **ustar** header blocks for global extended header records. The
102388 name shall be the contents of string, after the following character substitutions
102389 have been made:

102390 | *string* **Includes:** | **Replaced by:** |
102391 |---|---|
102392 | `%n` | An integer that represents the sequence number of the global extended header record in the archive, starting at 1. |
102394 | `%p` | The process ID of the *pax* process. |
102395 | `%%` | A `'%'` character. |

102396 Any other `'%'` characters in *string* produce undefined results.

102397 If no −**o globexthdr.name=string** is specified, *pax* shall use the following
102398 default value:

102399 `$TMPDIR/GlobalHead.%p.%n`

102400 where $*TMPDIR* represents the value of the *TMPDIR* environment variable. If
102401 *TMPDIR* is not set, *pax* shall use **/tmp**.

102402 **invalid**=*action*

102403 (Applicable only to the −**x pax** format.) This keyword allows user control over
102404 the action *pax* takes upon encountering values in an extended header record
102405 that, in **read** or **copy** mode, are invalid in the destination hierarchy or, in **list**
102406 mode, cannot be written in the codeset and current locale of the
102407 implementation. The following are invalid values that shall be recognized by
102408 *pax*:

102409 ‡ In **read** or **copy** mode, a filename or link name that contains character
102410 encodings invalid in the destination hierarchy. (For example, the name
102411 may contain embedded NULs.)

102412 ‡ In **read** or **copy** mode, a filename or link name that is longer than the
102413 maximum allowed in the destination hierarchy (for either a pathname
102414 component or the entire pathname).

102415 ‡ In **list** mode, any character string value (filename, link name, user name,
102416 and so on) that cannot be written in the codeset and current locale of the
102417 implementation.

102418 The following mutually-exclusive values of the *action* argument are supported:

102419 **binary** In **write** mode, *pax* shall generate a **hdrcharset**=**BINARY**
102420 extended header record for each file with a filename, link name,
102421 group name, owner name, or any other field in an extended
102422 header record that cannot be translated to the UTF-8 codeset,
102423 allowing the archive to contain the files with unencoded
102424 extended header record values. In **read** or **copy** mode, *pax* shall

use the values specified in the header without translation, regardless of whether this may overwrite an existing file with a valid name. In **list** mode, *pax* shall behave identically to the **bypass** action.

bypass In **read** or **copy** mode, *pax* shall bypass the file, causing no change to the destination hierarchy. In **list** mode, *pax* shall write all requested valid values for the file, but its method for writing invalid values is unspecified.

rename In **read** or **copy** mode, *pax* shall act as if the –**i** option were in effect for each file with invalid filename or link name values, allowing the user to provide a replacement name interactively. In **list** mode, *pax* shall behave identically to the **bypass** action.

UTF-8 When used in **read**, **copy**, or **list** mode and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the **pax** UTF-8 codeset format to the codeset and current locale of the implementation, *pax* shall use the actual UTF-8 encoding for the name. If a **hdrcharset** extended header record is in effect for this file, the character set specified by that record shall be used instead of UTF-8. If a **hdrcharset**=**BINARY** extended header record is in effect for this file, no translation shall be performed.

write In **read** or **copy** mode, *pax* shall write the file, translating the name, regardless of whether this may overwrite an existing file with a valid name. In **list** mode, *pax* shall behave identically to the **bypass** action.

If no –**o invalid=option** is specified, *pax* shall act as if –**oinvalid=bypass** were specified. Any overwriting of existing files that may be allowed by the –**oinvalid=** actions shall be subject to permission (–**p**) and modification time (–**u**) restrictions, and shall be suppressed if the –**k** option is also specified.

linkdata
(Applicable only to the –**x pax** format.) In **write** mode, *pax* shall write the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

listopt=*format*
This keyword specifies the output format of the table of contents produced when the –**v** option is specified in **list** mode. See List Mode Format Specifications (on page 3076). To avoid ambiguity, the **listopt=format** shall be the only or final **keyword=value** pair in a –**o** option-argument; all characters in the remainder of the option-argument shall be considered part of the format string. When multiple –**olistopt=format** options are specified, the format strings shall be considered a single, concatenated string, evaluated in command line order.

times
(Applicable only to the –**x** *pax* format.) When used in **write** or **copy** mode, *pax* shall include **atime** and **mtime** extended header records for each file. See pax Extended Header File Times (on page 3085).

In addition to these keywords, if the –**x** *pax* format is specified, any of the

102472 keywords and values defined in pax Extended Header (on page 3082), including
102473 implementation extensions, can be used in −**o** option-arguments, in either of two
102474 modes:

102475 **keyword**=*value*
102476 When used in **write** or **copy** mode, these keyword/value pairs shall be
102477 included at the beginning of the archive as **typeflag g** global extended header
102478 records. When used in **read** or **list** mode, these keyword/value pairs shall act
102479 as if they had been at the beginning of the archive as **typeflag g** global
102480 extended header records.

102481 **keyword**:=*value*
102482 When used in **write** or **copy** mode, these keyword/value pairs shall be
102483 included as records at the beginning of a **typeflag x** extended header for each
102484 file. (This shall be equivalent to the <equals-sign> form except that it creates
102485 no **typeflag g** global extended header records.) When used in **read** or **list**
102486 mode, these keyword/value pairs shall act as if they were included as records
102487 at the end of each extended header; thus, they shall override any global or file-
102488 specific extended header record keywords of the same names. For example, in
102489 the command:

102490 ```
102491 pax −r −o "
102492 gname:=mygroup,
" <archive
```

102493 the group name will be forced to a new value for all files read from the
102494 archive.

102495 The precedence of −**o** keywords over various fields in the archive is described in
102496 pax Extended Header Keyword Precedence (on page 3085). If the −**o**
102497 **delete**=*pattern*, −**o** **keyword**=*value*, or −**o** **keyword**:=*value* options are used to
102498 override or remove any extended header data needed to find files in an archive
102499 (e.g., `-o delete=size` for a file whose size cannot be represented in a **ustar**
102500 header or `-o size=100` for a file whose size is not 100 bytes), the behavior is
102501 undefined.

102502 −**p** *string* Specify one or more file characteristic options (privileges). The *string* option-
102503 argument shall be a string specifying file characteristics to be retained or discarded
102504 on extraction. The string shall consist of the specification characters `a`, `e`, `m`, `o`, and
102505 `p`. Other implementation-defined characters can be included. Multiple
102506 characteristics can be concatenated within the same string and multiple −**p** options
102507 can be specified. The meaning of the specification characters are as follows:

102508 `a` Do not preserve file access times.

102509 `e` Preserve the user ID, group ID, file mode bits (see XBD Section 3.169, on page
102510 60), access time, modification time, and any other implementation-defined file
102511 characteristics.

102512 `m` Do not preserve file modification times.

102513 `o` Preserve the user ID and group ID.

102514 `p` Preserve the file mode bits. Other implementation-defined file mode attributes
102515 may be preserved.

102516 In the preceding list, ``preserve'' indicates that an attribute stored in the archive
102517 shall be given to the extracted file, subject to the permissions of the invoking

  
```

process. The access and modification times of the file shall be preserved unless otherwise specified with the −**p** option or not stored in the archive. All attributes that are not preserved shall be determined as part of the normal file creation action (see Section 1.1.1.4, on page 2328).

If neither the `e` nor the `o` specification character is specified, or the user ID and group ID are not preserved for any reason, *pax* shall not set the S_ISUID and S_ISGID bits of the file mode.

If the preservation of any of these items fails for any reason, *pax* shall write a diagnostic message to standard error. Failure to preserve these items shall affect the final exit status, but shall not cause the extracted file to be deleted.

If file characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last shall take precedence. For example, if −**p** `eme` is specified, file modification times are preserved.

−**s** *replstr* Modify file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, using the syntax of the *ed* utility. The concepts of ``address'' and ``line'' are meaningless in the context of the *pax* utility, and shall not be supplied. The format shall be:

`−s /`*old*`/`*new*`/[gp]`

where as in *ed*, *old* is a basic regular expression and *new* can contain an <ampersand>, `'\n'` (where *n* is a digit) back-references, or subexpression matching. The *old* string shall also be permitted to contain <newline> characters.

Any non-null character can be used as a delimiter (`'/'` shown here). Multiple −**s** expressions can be specified; the expressions shall be applied in the order specified, terminating with the first successful substitution. The optional trailing `'g'` is as defined in the *ed* utility. The optional trailing `'p'` shall cause successful substitutions to be written to standard error. File or archive member names that substitute to the empty string shall be ignored when reading and writing archives.

−**t** When reading files from the file system, and if the user has the permissions required by *utime*() to do so, set the access time of each file read to the access time that it had before being read by *pax*.

−**u** Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name. In **read** mode, an archive member with the same name as a file in the file system shall be extracted if the archive member is newer than the file. In **write** mode, an archive file member with the same name as a file in the file system shall be superseded if the file is newer than the archive member. If −**a** is also specified, this is accomplished by appending to the archive; otherwise, it is unspecified whether this is accomplished by actual replacement in the archive or by appending to the archive. In **copy** mode, the file in the destination hierarchy shall be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.

−**v** In **list** mode, produce a verbose table of contents (see the STDOUT section). Otherwise, write archive member pathnames to standard error (see the STDERR section).

102562 –**x** *format* Specify the output archive format. The *pax* utility shall support the following
102563 formats:

102564 **cpio** The **cpio** interchange format; see the EXTENDED DESCRIPTION
102565 section. The default *blocksize* for this format for character special
102566 archive files shall be 5 120. Implementations shall support all
102567 *blocksize* values less than or equal to 32 256 that are multiples of 512.

102568 **pax** The **pax** interchange format; see the EXTENDED DESCRIPTION
102569 section. The default *blocksize* for this format for character special
102570 archive files shall be 5 120. Implementations shall support all
102571 *blocksize* values less than or equal to 32 256 that are multiples of 512.

102572 **ustar** The **tar** interchange format; see the EXTENDED DESCRIPTION
102573 section. The default *blocksize* for this format for character special
102574 archive files shall be 10 240. Implementations shall support all
102575 *blocksize* values less than or equal to 32 256 that are multiples of 512.

102576 Implementation-defined formats shall specify a default block size as well as any
102577 other block sizes supported for character special archive files.

102578 Any attempt to append to an archive file in a format different from the existing
102579 archive format shall cause *pax* to exit immediately with a non-zero exit status.

102580 –**X** When traversing the file hierarchy specified by a pathname, *pax* shall not descend
102581 into directories that have a different device ID (*st_dev*; see the System Interfaces
102582 volume of POSIX.1-2017, *stat*( )).

102583 Specifying more than one of the mutually-exclusive options –**H** and –**L** shall not be considered
102584 an error and the last option specified shall determine the behavior of the utility.

102585 The options that operate on the names of files or archive members (–**c**, –**i**, –**n**, –**s**, –**u**, and –**v**)
102586 shall interact as follows. In **read** mode, the archive members shall be selected based on the user-
102587 specified *pattern* operands as modified by the –**c**, –**n**, and –**u** options. Then, any –**s** and –**i**
102588 options shall modify, in that order, the names of the selected files. The –**v** option shall write
102589 names resulting from these modifications.

102590 In **write** mode, the files shall be selected based on the user-specified pathnames as modified by
102591 the –**n** and –**u** options. Then, any –**s** and –**i** options shall modify, in that order, the names of
102592 these selected files. The –**v** option shall write names resulting from these modifications.

102593 If both the –**u** and –**n** options are specified, *pax* shall not consider a file selected unless it is
102594 newer than the file to which it is compared.

102595 **List Mode Format Specifications**

102596 In **list** mode with the –**o listopt=format** option, the *format* argument shall be applied for each
102597 selected file. The *pax* utility shall append a <newline> to the **listopt** output for each selected file.
102598 The *format* argument shall be used as the *format* string described in XBD Chapter 5 (on page 121),
102599 with the exceptions 1. through 6. defined in the EXTENDED DESCRIPTION section of *printf*,
102600 plus the following exceptions:

102601 7. The sequence (*keyword*) can occur before a format conversion specifier. The conversion
102602 argument is defined by the value of *keyword*. The implementation shall support the
102603 following keywords:

‡ ńyAof the Field Name entries in Table 4-14 (on page 3086) and Table 4-16 (on page 3090). The implementation may support the *cpio* keywords without the leading **c_** in addition to the form required by Table 4-16 (on page 3090).

‡ ńyA keyword defined for the extended header in pax Extended Header (on page 3082).

‡ ńyAkeyword provided as an implementation-defined extension within the extended header defined in pax Extended Header (on page 3082).

For example, the sequence `"%(charset)s"` is the string value of the name of the character set in the extended header.

The result of the keyword conversion argument shall be the value from the applicable header field or extended header, without any trailing NULs.

All keyword values used as conversion arguments shall be translated from the UTF-8 encoding (or alternative encoding specified by any **hdrcharset** extended header record) to the character set appropriate for the local file system, user database, and so on, as applicable.

8. An additional conversion specifier character, `T`, shall be used to specify time formats. The `T` conversion specifier character can be preceded by the sequence (*keyword*=*subformat*), where *subformat* is a date format as defined by *date* operands. The default *keyword* shall be **mtime** and the default subformat shall be:

   ```
   %b %e %H:%M %Y
   ```

9. An additional conversion specifier character, `M`, shall be used to specify the file mode string as defined in *ls* Standard Output. If (*keyword*) is omitted, the **mode** keyword shall be used. For example, `%.1M` writes the single character corresponding to the <*entry type*> field of the *ls* **–l** command.

10. An additional conversion specifier character, `D`, shall be used to specify the device for block or special files, if applicable, in an implementation-defined format. If not applicable, and (*keyword*) is specified, then this conversion shall be equivalent to `%(`*keyword*`)u`. If not applicable, and (*keyword*) is omitted, then this conversion shall be equivalent to <space>.

11. An additional conversion specifier character, `F`, shall be used to specify a pathname. The `F` conversion character can be preceded by a sequence of <comma>-separated keywords:

    ```
    (keyword[,keyword] ... )
    ```

    The values for all the keywords that are non-null shall be concatenated together, each separated by a `'/'`. The default shall be (**path**) if the keyword **path** is defined; otherwise, the default shall be (**prefix**,**name**).

12. An additional conversion specifier character, `L`, shall be used to specify a symbolic link expansion. If the current file is a symbolic link, then `%L` shall expand to:

    ```
    "%s –> %s", <value of keyword>, <contents of link>
    ```

    Otherwise, the `%L` conversion specification shall be the equivalent of `%F`.

OPERANDS

The following operands shall be supported:

directory The destination directory pathname for **copy** mode.

file A pathname of a file to be copied or archived.

pattern A pattern matching one or more pathnames of archive members. A pattern must be given in the name-generating notation of the pattern matching notation in Section 2.13 (on page 2382), including the filename expansion rules in Section 2.13.3 (on page 2383). The default, if no *pattern* is specified, is to select all members in the archive.

STDIN

In **write** mode, the standard input shall be used only if no *file* operands are specified. It shall be a file containing a list of pathnames, each terminated by a <newline> character.

In **list** and **read** modes, if **−f** is not specified, the standard input shall be an archive file.

Otherwise, the standard input shall not be used.

INPUT FILES

The input file named by the *archive* option-argument, or standard input when the archive is read from there, shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section or some other implementation-defined format.

The file **/dev/tty** shall be used to write prompts and read responses.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pax*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the *pattern* operand, the basic regular expression for the **−s** option, and the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category, and pattern matching.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages and prompts written to standard error.

LC_TIME Determine the format and contents of date and time strings when the **−v** option is specified.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Determine the pathname that provides part of the default global extended header record file, as described for the **−o globexthdr=** keyword in the OPTIONS section.

TZ Determine the timezone used to calculate date and time strings when the **−v** option is specified. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In **write** mode, if **−f** is not specified, the standard output shall be the archive formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format (see **−x** *format*).

In **list** mode, when the **−olistopt**=*format* has been specified, the selected archive members shall be written to standard output using the format described under List Mode Format Specifications (on page 3076). In **list** mode without the **−olistopt**=*format* option, the table of contents of the selected archive members shall be written to standard output using the following format:

```
"%s\n", <pathname>
```

If the **−v** option is specified in **list** mode, the table of contents of the selected archive members shall be written to standard output using the following formats.

For pathnames representing hard links to previous members of the archive:

```
"%sΔ==Δ%s\n", <ls −l listing>, <linkname>
```

For all other pathnames:

```
"%s\n", <ls −l listing>
```

where <*ls* −l *listing*> shall be the format specified by the *ls* utility with the **−l** option. When writing pathnames in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of <blank>-separated fields shall be written.

In **list** mode, standard output shall not be buffered more than a pathname (plus any associated information and a <newline> terminator) at a time.

STDERR

If **−v** is specified in **read**, **write**, or **copy** modes, *pax* shall write the pathnames it processes to the standard error output using the following format:

```
"%s\n", <pathname>
```

These pathnames shall be written as soon as processing is begun on the file or archive member, and shall be flushed to standard error. The trailing <newline>, which shall not be buffered, is written when the file has been read or written.

If the **−s** option is specified, and the replacement string has a trailing `'p'`, substitutions shall be written to standard error in the following format:

```
"%sΔ>>Δ%s\n", <original pathname>, <new pathname>
```

In all operating modes of *pax*, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in pathnames or link names are written.

When using the **−xpax** archive format, if a filename, link name, group name, owner name, or any other field in an extended header record cannot be translated between the codeset in use for that

extended header record and the character set of the current locale, *pax* shall write a diagnostic message to standard error, shall process the file as described for the **−o invalid=** option, and then shall continue processing with the next file.

OUTPUT FILES

In **read** mode, the extracted output files shall be of the archived file type. In **copy** mode, the copied output files shall be the type of the file being copied. In either mode, existing files in the destination hierarchy shall be overwritten only when all permission (**−p**), modification time (**−u**), and invalid-value (**−oinvalid=**) tests allow it.

In **write** mode, the output file named by the **−f** option-argument shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format.

EXTENDED DESCRIPTION

pax Interchange Format

A *pax* archive tape or file produced in the **−xpax** format shall contain a series of blocks. The physical layout of the archive shall be identical to the **ustar** format described in ustar Interchange Format (on page 3086). Each file archived shall be represented by the following sequence:

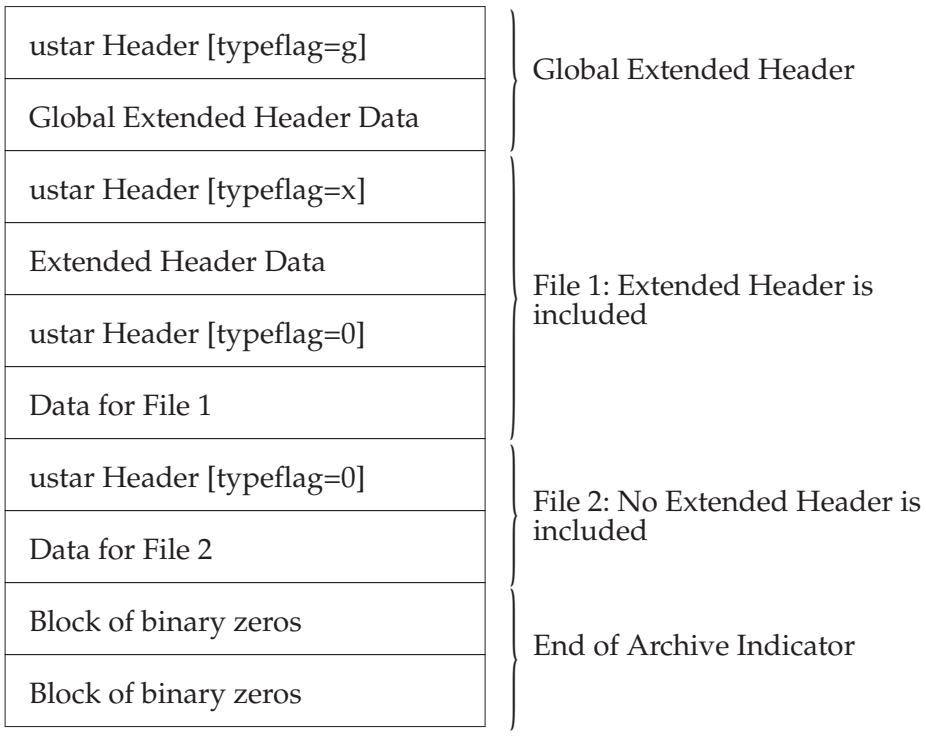
An optional header block with extended header records. This header block is of the form described in pax Header Block (on page 3081), with a *typeflag* value of **x** or **g**. The extended header records, described in pax Extended Header (on page 3082), shall be included as the data for this header block.

A header block that describes the file. Any fields in the preceding optional extended header shall override the associated fields in this header block for this file.

Zero or more blocks that contain the contents of the file.

At the end of the archive file there shall be two 512-byte blocks filled with binary zeros, interpreted as an end-of-archive indicator.

A schematic of an example archive with global extended header records and two actual files is shown in Figure 4-1 (on page 3081). In the example, the second file in the archive has no extended header preceding it, presumably because it has no need for extended attributes.



102759 **Figure 4-1** pax Format Archive Example

102760 **pax Header Block**

102761 The **pax** header block shall be identical to the **ustar** header block described in ustar Interchange
102762 Format (on page 3086), except that two additional *typeflag* values are defined:

102763 x Represents extended header records for the following file in the archive (which shall have
102764 its own **ustar** header block). The format of these extended header records shall be as
102765 described in pax Extended Header (on page 3082).

102766 g Represents global extended header records for the following files in the archive. The format
102767 of these extended header records shall be as described in pax Extended Header (on page
102768 3082). Each value shall affect all subsequent files that do not override that value in their
102769 own extended header record and until another global extended header record is reached
102770 that provides another value for the same field. The *typeflag* **g** global headers should not be
102771 used with interchange media that could suffer partial data loss in transporting the archive.

102772 For both of these types, the *size* field shall be the size of the extended header records in octets.
102773 The other fields in the header block are not meaningful to this version of the *pax* utility.
102774 However, if this archive is read by a *pax* utility conforming to the ISO POSIX-2: 1993 standard,
102775 the header block fields are used to create a regular file that contains the extended header records
102776 as data. Therefore, header block field values should be selected to provide reasonable file access
102777 to this regular file.

102778 A further difference from the **ustar** header block is that data blocks for files of *typeflag* 1 (the digit
102779 one) (hard link) may be included, which means that the size field may be greater than zero.
102780 Archives created by *pax* **–o linkdata** shall include these data blocks with the hard links.

pax Extended Header

A **pax** extended header contains values that are inappropriate for the **ustar** header block because of limitations in that format: fields requiring a character encoding other than that described in the ISO/IEC 646:1991 standard, fields representing file attributes not described in the **ustar** header, and fields whose format or length do not fit the requirements of the **ustar** header. The values in an extended header add attributes to the following file (or files; see the description of the *typeflag* **g** header block) or override values in the following header block(s), as indicated in the following list of keywords.

An extended header shall consist of one or more records, each constructed as follows:

`"%d %s=%s\n", <length>, <keyword>, <value>`

The extended header records shall be encoded according to the ISO/IEC 10646-1:2000 standard UTF-8 encoding. The <*length*> field, <blank>, <equals-sign>, and <newline> shown shall be limited to the portable character set, as encoded in UTF-8. The <*keyword*> fields can be any UTF-8 characters. The <*length*> field shall be the decimal length of the extended header record in octets, including the trailing <newline>. If there is a **hdrcharset** extended header in effect for a file, the *value* field for any **gname**, **linkpath**, **path**, and **uname** extended header records shall be encoded using the character set specified by the **hdrcharset** extended header record; otherwise, the *value* field shall be encoded using UTF-8. The *value* field for all other keywords specified by POSIX.1-2017 shall be encoded using UTF-8.

The <*keyword*> field shall be one of the entries from the following list or a keyword provided as an implementation extension. Keywords consisting entirely of lowercase letters, digits, and periods are reserved for future standardization. A keyword shall not include an <equals-sign>. (In the following list, the notations ``file(s)'' or ``block(s)'' is used to acknowledge that a keyword affects the following single file after a *typeflag* **x** extended header, but possibly multiple files after *typeflag* **g**. Any requirements in the list for *pax* to include a record when in **write** or **copy** mode shall apply only when such a record has not already been provided through the use of the **−o** option. When used in **copy** mode, *pax* shall behave as if an archive had been created with applicable extended header records and then extracted.)

atime The file access time for the following file(s), equivalent to the value of the *st_atime* member of the **stat** structure for a file, as described by the *stat*( ) function. The access time shall be restored if the process has appropriate privileges required to do so. The format of the <*value*> shall be as described in pax Extended Header File Times (on page 3085).

charset The name of the character set used to encode the data in the following file(s). The entries in the following table are defined to refer to known standards; additional names may be agreed on between the originator and recipient.

<value>	Formal Standard
ISO-IR-646-1990	ISO/IEC 646: 1990
ISO-IR-8859-1-1998	ISO/IEC 8859-1: 1998
ISO-IR-8859-2-1999	ISO/IEC 8859-2: 1999
ISO-IR-8859-3-1999	ISO/IEC 8859-3: 1999
ISO-IR-8859-4-1998	ISO/IEC 8859-4: 1998
ISO-IR-8859-5-1999	ISO/IEC 8859-5: 1999
ISO-IR-8859-6-1999	ISO/IEC 8859-6: 1999
ISO-IR-8859-7-1987	ISO/IEC 8859-7: 1987
ISO-IR-8859-8-1999	ISO/IEC 8859-8: 1999
ISO-IR-8859-9-1999	ISO/IEC 8859-9: 1999
ISO-IR-8859-10-1998	ISO/IEC 8859-10: 1998
ISO-IR-8859-13-1998	ISO/IEC 8859-13: 1998
ISO-IR-8859-14-1998	ISO/IEC 8859-14: 1998
ISO-IR-8859-15-1999	ISO/IEC 8859-15: 1999
ISO-IR-10646-2000	ISO/IEC 10646: 2000
ISO-IR-10646-2000-UTF-8	ISO/IEC 10646, UTF-8 encoding
BINARY	None.

The encoding is included in an extended header for information only; when *pax* is used as described in POSIX.1-2017, it shall not translate the file data into any other encoding. The **BINARY** entry indicates unencoded binary data.

When used in **write** or **copy** mode, it is implementation-defined whether *pax* includes a **charset** extended header record for a file.

comment A series of characters used as a comment. All characters in the <*value*> field shall be ignored by *pax*.

gid The group ID of the group that owns the file, expressed as a decimal number using digits from the ISO/IEC 646: 1991 standard. This record shall override the *gid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *gid* extended header record for each file whose group ID is greater than 2 097 151 (octal 7 777 777).

gname The group of the file(s), formatted as a group name in the group database. This record shall override the *gid* and *gname* fields in the following header block(s), and any *gid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the characters cannot be translated, and if neither the **−oinvalid=UTF-8** option nor the **−oinvalid=binary** option is specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **gname** extended header record for each file whose group name cannot be represented entirely with the letters and digits of the portable character set.

hdrcharset The name of the character set used to encode the value field of the **gname**, **linkpath**, **path**, and **uname** *pax* extended header records. The entries in the following table are defined to refer to known standards; additional names may be agreed between the originator and the recipient.

<value>	Formal Standard
ISO-IRΔ10646Δ2000ΔUTF-8	ISO/IEC 10646, UTF-8 encoding
BINARY	None.

If no **hdrcharset** extended header record is specified, the default character set used to encode all values in extended header records shall be the ISO/IEC 10646-1: 2000 standard UTF-8 encoding.

The **BINARY** entry indicates that all values recorded in extended headers for affected files are unencoded binary data from the underlying system.

linkpath The pathname of a link being created to another file, of any type, previously archived. This record shall override the *linkname* field in the following **ustar** header block(s). The following **ustar** header block shall determine the type of link created. If *typeflag* of the following header block is 1, it shall be a hard link. If *typeflag* is 2, it shall be a symbolic link and the **linkpath** value shall be the contents of the symbolic link. The *pax* utility shall translate the name of the link (contents of the symbolic link) from the encoding in the header to the character set appropriate for the local file system. When used in **write** or **copy** mode, *pax* shall include a **linkpath** extended header record for each link whose pathname cannot be represented entirely with the members of the portable character set other than NUL.

mtime The file modification time of the following file(s), equivalent to the value of the *st_mtime* member of the **stat** structure for a file, as described in the *stat*( ) function. This record shall override the *mtime* field in the following header block(s). The modification time shall be restored if the process has appropriate privileges required to do so. The format of the <*value*> shall be as described in pax Extended Header File Times (on page 3085).

path The pathname of the following file(s). This record shall override the *name* and *prefix* fields in the following header block(s). The *pax* utility shall translate the pathname of the file from the encoding in the header to the character set appropriate for the local file system.

When used in **write** or **copy** mode, *pax* shall include a *path* extended header record for each file whose pathname cannot be represented entirely with the members of the portable character set other than NUL.

realtime.*any* The keywords prefixed by ``realtime.'' are reserved for future standardization.

security.*any* The keywords prefixed by ``security.'' are reserved for future standardization.

size The size of the file in octets, expressed as a decimal number using digits from the ISO/IEC 646: 1991 standard. This record shall override the *size* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *size* extended header record for each file with a size value greater than 8 589 934 591 (octal 77 777 777 777).

uid The user ID of the file owner, expressed as a decimal number using digits from the ISO/IEC 646: 1991 standard. This record shall override the *uid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *uid* extended header record for each file whose owner ID is greater than 2 097 151 (octal 7 777 777).

uname The owner of the following file(s), formatted as a user name in the user database. This record shall override the *uid* and *uname* fields in the following header block(s), and any *uid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the encoding in the header record to the character set appropriate for the user database on the receiving system. If any of the characters cannot be translated, and if neither the −**oinvalid=UTF-8** option nor the −**oinvalid=binary** option is specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **uname** extended header record for each file whose user name cannot be represented entirely with the letters and digits of the portable character set.

If the <*value*> field is zero length, it shall delete any header block field, previously entered extended header value, or global extended header value of the same name.

If a keyword in an extended header record (or in a −**o** option-argument) overrides or deletes a corresponding field in the **ustar** header block, *pax* shall ignore the contents of that header block field.

Unlike the **ustar** header block fields, NULs shall not delimit <*value*>s; all characters within the <*value*> field shall be considered data for the field. None of the length limitations of the **ustar** header block fields in Table 4-14 (on page 3086) shall apply to the extended header records.

pax Extended Header Keyword Precedence

This section describes the precedence in which the various header records and fields and command line options are selected to apply to a file in the archive. When *pax* is used in **read** or **list** modes, it shall determine a file attribute in the following sequence:

1. If −**odelete=keyword-prefix** is used, the affected attributes shall be determined from step 7., if applicable, or ignored otherwise.
2. If −**o***keyword*:= is used, the affected attributes shall be ignored.
3. If −**okeyword:=value** is used, the affected attribute shall be assigned the value.
4. If there is a *typeflag* **x** extended header record, the affected attribute shall be assigned the <*value*>. When extended header records conflict, the last one given in the header shall take precedence.
5. If −**okeyword=value** is used, the affected attribute shall be assigned the value.
6. If there is a *typeflag* **g** global extended header record, the affected attribute shall be assigned the <*value*>. When global extended header records conflict, the last one given in the global header shall take precedence.
7. Otherwise, the attribute shall be determined from the **ustar** header block.

pax Extended Header File Times

The *pax* utility shall write an **mtime** record for each file in **write** or **copy** modes if the file's modification time cannot be represented exactly in the **ustar** header logical record described in ustar Interchange Format (on page 3086). This can occur if the time is out of **ustar** range, or if the file system of the underlying implementation supports non-integer time granularities and the time is not an integer. All of these time records shall be formatted as a decimal representation of the time in seconds since the Epoch. If a <period> (`'.'`) decimal point character is present, the digits to the right of the point shall represent the units of a subsecond timing granularity, where the first digit is tenths of a second and each subsequent digit is a tenth of the previous digit. In **read** or **copy** mode, the *pax* utility shall truncate the time of a file to the greatest value

that is not greater than the input header file time. In **write** or **copy** mode, the *pax* utility shall output a time exactly if it can be represented exactly as a decimal number, and otherwise shall generate only enough digits so that the same time shall be recovered if the file is extracted on a system whose underlying implementation supports the same time granularity.

ustar Interchange Format

A **ustar** archive tape or file shall contain a series of logical records. Each logical record shall be a fixed-size logical record of 512 octets (see below). Although this format may be thought of as being stored on 9-track industry-standard 12.7 mm (0.5 in) magnetic tape, other types of transportable media are not excluded. Each file archived shall be represented by a header logical record that describes the file, followed by zero or more logical records that give the contents of the file. At the end of the archive file there shall be two 512-octet logical records filled with binary zeros, interpreted as an end-of-archive indicator.

The logical records may be grouped for physical I/O operations, as described under the −**b***blocksize* and −**x ustar** options. Each group of logical records may be written with a single operation equivalent to the *write*( ) function. On magnetic tape, the result of this write shall be a single tape physical block. The last physical block shall always be the full size, so logical records after the two zero logical records may contain undefined data.

The header logical record shall be structured as shown in the following table. All lengths and offsets are in decimal.

Table 4-14 ustar Header Block

Field Name	Octet Offset	Length (in Octets)
name	0	100
mode	100	8
uid	108	8
gid	116	8
size	124	12
mtime	136	12
chksum	148	8
typeflag	156	1
linkname	157	100
magic	257	6
version	263	2
uname	265	32
gname	297	32
devmajor	329	8
devminor	337	8
prefix	345	155

All characters in the header logical record shall be represented in the coded character set of the ISO/IEC 646: 1991 standard. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside of <slash> and the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes.

However, the *pax* utility shall never create filenames on the local system that cannot be accessed

via the procedures described in POSIX.1-2017. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored. The *pax* utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.

Each field within the header logical record is contiguous; that is, there is no padding used. Each character on the archive medium shall be stored contiguously.

The fields *magic*, *uname*, and *gname* are character strings each terminated by a NUL character. The fields *name*, *linkname*, and *prefix* are NUL-terminated character strings except when all characters in the array contain non-NUL characters including the last character. The *version* field is two octets containing the characters "00" (zero-zero). The *typeflag* contains a single character. All other fields are leading zero-filled octal numbers using digits from the ISO/IEC 646:1991 standard IRV. Each numeric field is terminated by one or more <space> or NUL characters.

The *name* and the *prefix* fields shall produce the pathname of the file. A new pathname shall be formed, if *prefix* is not an empty string (its first character is not NUL), by concatenating *prefix* (up to the first NUL character), a <slash> character, and *name*; otherwise, *name* is used alone. In either case, *name* is terminated at the first NUL character. If *prefix* begins with a NUL character, it shall be ignored. In this manner, pathnames of at most 256 characters can be supported. If a pathname does not fit in the space provided, *pax* shall notify the user of the error, and shall not store any part of the file ‡header or data ‡on the medium.

The *linkname* field, described below, shall not use the *prefix* to produce a pathname. As such, a *linkname* is limited to 100 characters. If the name does not fit in the space provided, *pax* shall notify the user of the error, and shall not attempt to store the link on the medium.

The *mode* field provides 12 bits encoded in the ISO/IEC 646:1991 standard octal digit representation. The encoded bits shall represent the following values:

Table 4-15 ustar *mode* Field

Bit Value	POSIX.1-2017 Bit	Description
04 000	S_ISUID	Set UID on execution.
02 000	S_ISGID	Set GID on execution.
01 000	<reserved>	Reserved for future standardization.
00 400	S_IRUSR	Read permission for file owner class.
00 200	S_IWUSR	Write permission for file owner class.
00 100	S_IXUSR	Execute/search permission for file owner class.
00 040	S_IRGRP	Read permission for file group class.
00 020	S_IWGRP	Write permission for file group class.
00 010	S_IXGRP	Execute/search permission for file group class.
00 004	S_IROTH	Read permission for file other class.
00 002	S_IWOTH	Write permission for file other class.
00 001	S_IXOTH	Execute/search permission for file other class.

When appropriate privileges are required to set one of these mode bits, and the user restoring the files from the archive does not have appropriate privileges, the mode bits for which the user does not have appropriate privileges shall be ignored. Some of the mode bits in the archive format are not mentioned elsewhere in this volume of POSIX.1-2017. If the implementation does not support those bits, they may be ignored.

The *uid* and *gid* fields are the user and group ID of the owner and group of the file, respectively.

The *size* field is the size of the file in octets. If the *typeflag* field is set to specify a file to be of type 1 (a link) or 2 (a symbolic link), the *size* field shall be specified as zero. If the *typeflag* field is set to

specify a file of type 5 (directory), the *size* field shall be interpreted as described under the definition of that record type. No data logical records are stored for types 1, 2, or 5. If the *typeflag* field is set to 3 (character special file), 4 (block special file), or 6 (FIFO), the meaning of the *size* field is unspecified by this volume of POSIX.1-2017, and no data logical records shall be stored on the medium. Additionally, for type 6, the *size* field shall be ignored when reading. If the *typeflag* field is set to any other value, the number of logical records written following the header shall be (*size*+511)/512, ignoring any fraction in the result of the division.

The *mtime* field shall be the modification time of the file at the time it was archived. It is the ISO/IEC 646:1991 standard representation of the octal value of the modification time obtained from the *stat*( ) function.

The *chksum* field shall be the ISO/IEC 646:1991 standard IRV representation of the octal value of the simple sum of all octets in the header logical record. Each octet in the header shall be treated as an unsigned value. These values shall be added to an unsigned integer, initialized to zero, the precision of which is not less than 17 bits. When calculating the checksum, the *chksum* field is treated as if it were all <space> characters.

The *typeflag* field specifies the type of file archived. If a particular implementation does not recognize the type, or the user does not have appropriate privileges to create that type, the file shall be extracted as if it were a regular file if the file type is defined to have a meaning for the *size* field that could cause data logical records to be written on the medium (see the previous description for *size*). If conversion to a regular file occurs, the *pax* utility shall produce an error indicating that the conversion took place. All of the *typeflag* fields shall be coded in the ISO/IEC 646:1991 standard IRV:

`0` Represents a regular file. For backwards-compatibility, a *typeflag* value of binary zero (`'\0'`) should be recognized as meaning a regular file when extracting files from the archive. Archives written with this version of the archive file format create regular files with a *typeflag* value of the ISO/IEC 646:1991 standard IRV `'0'`.

`1` Represents a file linked to another file, of any type, previously archived. Such files are identified by having the same device and file serial numbers, and pathnames that refer to different directory entries. All such files shall be archived as linked files. The linked-to name is specified in the *linkname* field with a NUL-character terminator if it is less than 100 octets in length.

`2` Represents a symbolic link. The contents of the symbolic link shall be stored in the *linkname* field.

`3,4` Represent character special files and block special files respectively. In this case the *devmajor* and *devminor* fields shall contain information defining the device, the format of which is unspecified by this volume of POSIX.1-2017. Implementations may map the device specifications to their own local specification or may ignore the entry.

`5` Specifies a directory or subdirectory. On systems where disk allocation is performed on a directory basis, the *size* field shall contain the maximum number of octets (which may be rounded to the nearest disk block allocation unit) that the directory may hold. A *size* field of zero indicates no such limiting. Systems that do not support limiting in this manner should ignore the *size* field.

`6` Specifies a FIFO special file. Note that the archiving of a FIFO file archives the existence of this file and not its contents.

`7` Reserved to represent a file to which an implementation has associated some high-performance attribute. Implementations without such extensions should treat this file as a regular file (type 0).

103087 A–Z The letters 'A' to 'Z', inclusive, are reserved for custom implementations. All other
103088 values are reserved for future versions of this standard.

103089 It is unspecified whether files with pathnames that refer to the same directory entry are archived
103090 as linked files or as separate files. If they are archived as linked files, this means that attempting
103091 to extract both pathnames from the resulting archive will always cause an error (unless the **–u**
103092 option is used) because the link cannot be created.

103093 It is unspecified whether files with the same device and file serial numbers being appended to
103094 an archive are treated as linked files to members that were in the archive before the append.

103095 Attempts to archive a socket shall produce a diagnostic message when **ustar** interchange format
103096 is used, but may be allowed when **pax** interchange format is used. Handling of other file types is
103097 implementation-defined.

103098 The *magic* field is the specification that this archive was output in this archive format. If this field
103099 contains **ustar** (the five characters from the ISO/IEC 646:1991 standard IRV shown followed by
103100 NUL), the *uname* and *gname* fields shall contain the ISO/IEC 646:1991 standard IRV
103101 representation of the owner and group of the file, respectively (truncated to fit, if necessary).
103102 When the file is restored by a privileged, protection-preserving version of the utility, the user
103103 and group databases shall be scanned for these names. If found, the user and group IDs
103104 contained within these files shall be used rather than the values contained within the *uid* and *gid*
103105 fields.

103106 **cpio Interchange Format**

103107 The octet-oriented **cpio** archive format shall be a series of entries, each comprising a header that
103108 describes the file, the name of the file, and then the contents of the file.

103109 An archive may be recorded as a series of fixed-size blocks of octets. This blocking shall be used
103110 only to make physical I/O more efficient. The last group of blocks shall always be at the full
103111 size.

103112 For the octet-oriented **cpio** archive format, the individual entry information shall be in the order
103113 indicated and described by the following table; see also the **<cpio.h>** header.

Table 4-16 Octet-Oriented cpio Archive Entry

Header Field Name	Length (in Octets)	Interpreted as
c_magic	6	Octal number
c_dev	6	Octal number
c_ino	6	Octal number
c_mode	6	Octal number
c_uid	6	Octal number
c_gid	6	Octal number
c_nlink	6	Octal number
c_rdev	6	Octal number
c_mtime	11	Octal number
c_namesize	6	Octal number
c_filesize	11	Octal number
Filename Field Name	**Length**	**Interpreted as**
c_name	*c_namesize*	Pathname string
File Data Field Name	**Length**	**Interpreted as**
c_filedata	*c_filesize*	Data

cpio Header

For each file in the archive, a header as defined previously shall be written. The information in the header fields is written as streams of the ISO/IEC 646: 1991 standard characters interpreted as octal numbers. The octal numbers shall be extended to the necessary length by appending the ISO/IEC 646: 1991 standard IRV zeros at the most-significant-digit end of the number; the result is written to the most-significant digit of the stream of octets first. The fields shall be interpreted as follows:

c_magic Identify the archive as being a transportable archive by containing the identifying value "`070707`".

c_dev, *c_ino* Contains values that uniquely identify the file within the archive (that is, no files contain the same pair of *c_dev* and *c_ino* values unless they are links to the same file). The values shall be determined in an unspecified manner.

c_mode Contains the file type and access permissions as defined in the following table.

Table 4-17 Values for cpio c_mode Field

File Permissions Name	Value	Indicates
C_IRUSR	000 400	Read by owner
C_IWUSR	000 200	Write by owner
C_IXUSR	000 100	Execute by owner
C_IRGRP	000 040	Read by group
C_IWGRP	000 020	Write by group
C_IXGRP	000 010	Execute by group
C_IROTH	000 004	Read by others
C_IWOTH	000 002	Write by others
C_IXOTH	000 001	Execute by others
C_ISUID	004 000	Set *uid*
C_ISGID	002 000	Set *gid*
C_ISVTX	001 000	Reserved
File Type Name	**Value**	**Indicates**
C_ISDIR	040 000	Directory
C_ISFIFO	010 000	FIFO
C_ISREG	0100 000	Regular file
C_ISLNK	0120 000	Symbolic link
C_ISBLK	060 000	Block special file
C_ISCHR	020 000	Character special file
C_ISSOCK	0140 000	Socket
C_ISCTG	0110 000	Reserved

Directories, FIFOs, symbolic links, and regular files shall be supported on a system conforming to this volume of POSIX.1-2017; additional values defined previously are reserved for compatibility with existing systems. Additional file types may be supported; however, such files should not be written to archives intended to be transported to other systems.

c_uid Contains the user ID of the owner.

c_gid Contains the group ID of the group.

c_nlink Contains a number greater than or equal to the number of links in the archive referencing the file. If the **−a** option is used to append to a *cpio* archive, then the *pax* utility need not account for the files in the existing part of the archive when calculating the *c_nlink* values for the appended part of the archive, and need not alter the *c_nlink* values in the existing part of the archive if additional files with the same *c_dev* and *c_ino* values are appended to the archive.

c_rdev Contains implementation-defined information for character or block special files.

c_mtime Contains the latest time of modification of the file at the time the archive was created.

c_namesize Contains the length of the pathname, including the terminating NUL character.

c_filesize Contains the length in octets of the data section following the header structure.

cpio Filename

The *c_name* field shall contain the pathname of the file. The length of this field in octets is the value of *c_namesize*.

If a filename is found on the medium that would create an invalid pathname, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored.

All characters shall be represented in the ISO/IEC 646:1991 standard IRV. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes. However, the *pax* utility shall never create filenames on the local system that cannot be accessed via the procedures described previously in this volume of POSIX.1-2017. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the local file system and under what name it is stored. The *pax* utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.

cpio File Data

Following *c_name*, there shall be *c_filesize* octets of data. Interpretation of such data occurs in a manner dependent on the file. For regular files, the data shall consist of the contents of the file. For symbolic links, the data shall consist of the contents of the symbolic link. If *c_filesize* is zero, no data shall be contained in *c_filedata*.

When restoring from an archive:

> If the user does not have appropriate privileges to create a file of the specified type, *pax* shall ignore the entry and write an error message to standard error.
>
> Only regular files and symbolic links have data to be restored. Presuming a regular file meets any selection criteria that might be imposed on the format-reading utility by the user, such data shall be restored.
>
> If a user does not have appropriate privileges to set a particular mode flag, the flag shall be ignored. Some of the mode flags in the archive format are not mentioned elsewhere in this volume of POSIX.1-2017. If the implementation does not support those flags, they may be ignored.

cpio Special Entries

FIFO special files, directories, and the trailer shall be recorded with *c_filesize* equal to zero. Symbolic links shall be recorded with *c_filesize* equal to the length of the contents of the symbolic link. For other special files, *c_filesize* is unspecified by this volume of POSIX.1-2017. The header for the next file entry in the archive shall be written directly after the last octet of the file entry preceding it. A header denoting the filename **TRAILER!!!** shall indicate the end of the archive; the contents of octets in the last block of the archive following such a header are undefined.

EXIT STATUS

The following exit values shall be returned:

0 All files were processed successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If *pax* cannot create a file or a link when reading an archive or cannot find a file when writing an archive, or cannot preserve the user ID, group ID, or file mode when the **−p** option is specified, a diagnostic message shall be written to standard error and a non-zero exit status shall be returned, but processing shall continue. In the case where *pax* cannot create a link to a file, *pax* shall not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, *pax* may have only partially extracted the file or (if the **−n** option was not specified) may have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories may have additional bits from the S_IRWXU mask set as well as incorrect modification and access times.

APPLICATION USAGE

Caution is advised when using the **−a** option to append to a *cpio* format archive. If any of the files being appended happen to be given the same *c_dev* and *c_ino* values as a file in the existing part of the archive, then they may be treated as links to that file on extraction. Thus, it is risky to use **−a** with *cpio* format except when it is done on the same system that the original archive was created on, and with the same *pax* utility, and in the knowledge that there has been little or no file system activity since the original archive was created that could lead to any of the files appended being given the same *c_dev* and *c_ino* values as an unrelated file in the existing part of the archive. Also, when (intentionally) appending additional links to a file in the existing part of the archive, the *c_nlink* values in the modified archive can be smaller than the number of links to the file in the archive, which may mean that the links are not preserved on extraction.

The **−p** (privileges) option was invented to reconcile differences between historical *tar* and *cpio* implementations. In particular, the two utilities use **−m** in diametrically opposed ways. The **−p** option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it may seem complex, there are really two modes that are most commonly used:

−p e ``Preserve everything''. This would be used by the historical superuser, someone with all appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The **e** flag is the sum of **o** and **p**, and other implementation-defined attributes.

−p p ``Preserve'' the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.

The one pathname per line format of standard input precludes pathnames containing <newline> characters. Although such pathnames violate the portable filename guidelines, they may exist and their presence may inhibit usage of *pax* within shell scripts. This problem is inherited from historical archive programs. The problem can be avoided by listing filename arguments on the command line instead of on standard input.

It is almost certain that appropriate privileges are required for *pax* to accomplish parts of this volume of POSIX.1-2017. Specifically, creating files of type block special or character special, restoring file access times unless the files are owned by the user (the **−t** option), or preserving file owner, group, and mode (the **−p** option) all probably require appropriate privileges.

In **read** mode, implementations are permitted to overwrite files when the archive has multiple members with the same name. This may fail if permissions on the first version of the file do not permit it to be overwritten.

The **cpio** and **ustar** formats can only support files up to 8 589 934 592 bytes (8 * 2^30) in size.

When archives containing binary header information are listed , the filenames printed may cause strange behavior on some terminals.

When all of the following are true:

1. A file of type directory is being placed into an archive.
2. The **ustar** archive format is being used.
3. The pathname of the directory is less than or equal to 155 bytes long (it will fit in the *prefix* field in the **ustar** header block).
4. The last component of the pathname of the directory is longer than 100 bytes long (it will not fit in the *name* field in the **ustar** header block).

some implementations of the *pax* utility will place the entire directory pathname in the *prefix* field, set the *name* field to an empty string, and place the directory in the archive. Other implementations of the *pax* utility will give an error under these conditions because the *name* field is not large enough to hold the last component of the directory name. This standard allows either behavior. However, when extracting a directory from a **ustar** format archive, this standard requires that all implementations be able to extract a directory even if the *name* field contains an empty string as long as the *prefix* field does not also contain an empty string.

EXAMPLES

The following command:

```
pax -w -f /dev/rmt/1m .
```

copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures—the historical BSD device name would be **/dev/rmt9**).

The following commands:

```
mkdir newdir
pax -rw olddir newdir
```

copy the *olddir* directory hierarchy to *newdir*.

```
pax -r -s ',^//*usr//*,,' -f a.pax
```

reads the archive **a.pax**, with all files rooted in **/usr** in the archive extracted relative to the current directory.

Using the option:

```
-o listopt="%M %(atime)T %(size)D %(name)s"
```

overrides the default output description in Standard Output and instead writes:

```
-rw-rw--- Jan 12 15:53 2003 1492 /usr/foo/bar
```

Using the options:

```
-o listopt='%L\t%(size)D\n%.7' \
-o listopt='(name)s\n%(atime)T\n%T'
```

overrides the default output description in Standard Output and instead writes:

```
/usr/foo/bar -> /tmp   1492
/usr/fo
Jan 12 15:53 1991
```

103314 Jan 31 15:53 2003

103315 **RATIONALE**

103316 The *pax* utility was new for the ISO POSIX-2: 1993 standard. It represents a peaceful compromise
103317 between advocates of the historical *tar* and *cpio* utilities.

103318 A fundamental difference between *cpio* and *tar* was in the way directories were treated. The *cpio*
103319 utility did not treat directories differently from other files, and to select a directory and its
103320 contents required that each file in the hierarchy be explicitly specified. For *tar*, a directory
103321 matched every file in the file hierarchy it rooted.

103322 The *pax* utility offers both interfaces; by default, directories map into the file hierarchy they root.
103323 The **−d** option causes *pax* to skip any file not explicitly referenced, as *cpio* historically did. The *tar*
103324 *−style* behavior was chosen as the default because it was believed that this was the more
103325 common usage and because *tar* is the more commonly available interface, as it was historically
103326 provided on both System V and BSD implementations.

103327 The data interchange format specification in this volume of POSIX.1-2017 requires that processes
103328 with ``appropriate privileges'' shall always restore the ownership and permissions of extracted
103329 files exactly as archived. If viewed from the historic equivalence between superuser and
103330 ``appropriate privileges'', there are two problems with this requirement. First, users running as
103331 superusers may unknowingly set dangerous permissions on extracted files. Second, it is
103332 needlessly limiting, in that superusers cannot extract files and own them as superuser unless the
103333 archive was created by the superuser. (It should be noted that restoration of ownerships and
103334 permissions for the superuser, by default, is historical practice in *cpio*, but not in *tar*.) In order to
103335 avoid these two problems, the *pax* specification has an additional ``privilege'' mechanism, the **−p**
103336 option. Only a *pax* invocation with the privileges needed, and which has the **−p** option set using
103337 the `e` specification character, has appropriate privileges to restore full ownership and permission
103338 information.

103339 Note also that this volume of POSIX.1-2017 requires that the file ownership and access
103340 permissions shall be set, on extraction, in the same fashion as the *creat*( ) function when provided
103341 with the mode stored in the archive. This means that the file creation mask of the user is applied
103342 to the file permissions.

103343 Users should note that directories may be created by *pax* while extracting files with permissions
103344 that are different from those that existed at the time the archive was created. When extracting
103345 sensitive information into a directory hierarchy that no longer exists, users are encouraged to set
103346 their file creation mask appropriately to protect these files during extraction.

103347 The table of contents output is written to standard output to facilitate pipeline processing.

103348 An early proposal had hard links displaying for all pathnames. This was removed because it
103349 complicates the output of the case where **−v** is not specified and does not match historical *cpio*
103350 usage. The hard-link information is available in the **−v** display.

103351 The description of the **−l** option allows implementations to make hard links to symbolic links.
103352 Earlier versions of this standard did not specify any way to create a hard link to a symbolic link,
103353 but many implementations provided this capability as an extension. If there are hard links to
103354 symbolic links when an archive is created, the implementation is required to archive the hard
103355 link in the archive (unless **−H** or **−L** is specified). When in **read** mode and in **copy** mode,
103356 implementations supporting hard links to symbolic links should use them when appropriate.

103357 The archive formats inherited from the POSIX.1-1990 standard have certain restrictions that have
103358 been brought along from historical usage. For example, there are restrictions on the length of
103359 pathnames stored in the archive. When *pax* is used in **copy**(**−rw**) mode (copying directory
103360 hierarchies), the ability to use extensions from the **−xpax** format overcomes these restrictions.

The default *blocksize* value of 5 120 bytes for *cpio* was selected because it is one of the standard block-size values for *cpio*, set when the −**B** option is specified. (The other default block-size value for *cpio* is 512 bytes, and this was considered to be too small.) The default block value of 10 240 bytes for *tar* was selected because that is the standard block-size value for BSD *tar*. The maximum block size of 32 256 bytes (2^{15}–512 bytes) is the largest multiple of 512 bytes that fits into a signed 16-bit tape controller transfer register. There are known limitations in some historical systems that would prevent larger blocks from being accepted. Historical values were chosen to improve compatibility with historical scripts using *dd* or similar utilities to manipulate archives. Also, default block sizes for any file type other than character special file has been deleted from this volume of POSIX.1-2017 as unimportant and not likely to affect the structure of the resulting archive.

Implementations are permitted to modify the block-size value based on the archive format or the device to which the archive is being written. This is to provide implementations with the opportunity to take advantage of special types of devices, and it should not be used without a great deal of consideration as it almost certainly decreases archive portability.

The intended use of the −**n** option was to permit extraction of one or more files from the archive without processing the entire archive. This was viewed by the standard developers as offering significant performance advantages over historical implementations. The −**n** option in early proposals had three effects; the first was to cause special characters in patterns to not be treated specially. The second was to cause only the first file that matched a pattern to be extracted. The third was to cause *pax* to write a diagnostic message to standard error when no file was found matching a specified pattern. Only the second behavior is retained by this volume of POSIX.1-2017, for many reasons. First, it is in general not acceptable for a single option to have multiple effects. Second, the ability to make pattern matching characters act as normal characters is useful for parts of *pax* other than file extraction. Third, a finer degree of control over the special characters is useful because users may wish to normalize only a single special character in a single filename. Fourth, given a more general escape mechanism, the previous behavior of the −**n** option can be easily obtained using the −**s** option or a *sed* script. Finally, writing a diagnostic message when a pattern specified by the user is unmatched by any file is useful behavior in all cases.

In this version, the −**n** was removed from the **copy** mode synopsis of *pax*; it is inapplicable because there are no pattern operands specified in this mode.

There is another method than *pax* for copying subtrees in POSIX.1-2017 described as part of the *cp* utility. Both methods are historical practice: *cp* provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

A single archive may span more than one file. It is suggested that implementations provide informative messages to the user on standard error whenever the archive file is changed.

The −**d** option (do not create intermediate directories not listed in the archive) found in early proposals was originally provided as a complement to the historic −**d** option of *cpio*. It has been deleted.

The −**s** option in early proposals specified a subset of the substitution command from the *ed* utility. As there was no reason for only a subset to be supported, the −**s** option is now compatible with the current *ed* specification. Since the delimiter can be any non-null character, the following

usage with single <space> characters is valid:

```
pax −s " foo bar " ...
```

The −**t** description is worded so as to note that this may cause the access time update caused by some other activity (which occurs while the file is being read) to be overwritten.

The default behavior of *pax* with regard to file modification times is the same as historical implementations of *tar*. It is not the historical behavior of *cpio*.

Because the −**i** option uses **/dev/tty**, utilities without a controlling terminal are not able to use this option.

The −**y** option, found in early proposals, has been deleted because a line containing a single <period> for the −**i** option has equivalent functionality. The special lines for the −**i** option (a single <period> and the empty line) are historical practice in *cpio*.

In early drafts, a −**e***charmap* option was included to increase portability of files between systems using different coded character sets. This option was omitted because it was apparent that consensus could not be formed for it. In this version, the use of UTF-8 should be an adequate substitute.

The ISO POSIX-2:1993 standard and ISO POSIX-1 standard requirements for *pax*, however, made it very difficult to create a single archive containing files created using extended characters provided by different locales. This version adds the **hdrcharset** keyword to make it possible to archive files in these cases without dropping files due to translation errors.

Translating filenames and other attributes from a locale's encoding to UTF-8 and then back again can lose information, as the resulting filename might not be byte-for-byte equivalent to the original. To avoid this problem, users can specify the −**o hdrcharset=binary** option, which will cause the resulting archive to use binary format for all names and attributes. Such archives are not portable among hosts that use different native encodings (e.g., EBCDIC *versus* ASCII-based encodings), but they will allow interchange among the vast majority of POSIX file systems in practical use. Also, the −**o hdrcharset=binary** option will cause *pax* in **copy** mode to behave more like other standard utilities such as *cp*.

If the values specified by the −**o exthdr.name=value**, −**o globexthdr.name=value**, or by **$TMPDIR** (if −**o globexthdr.name** is not specified) require a character encoding other than that described in the ISO/IEC 646:1991 standard, a **path** extended header record will have to be created for the file. If a **hdrcharset** extended header record is active for such headers, it will determine the codeset used for the value field in these extended **path** header records. These **path** extended header records always need to be created when writing an archive even if **hdrcharset=binary** has been specified and would contain the same (binary) data that appears in the **ustar** header record prefix and *name* fields. (In other words, an extended header **path** record is always required to be generated if the *prefix* or *name* fields contain non-ASCII characters even when **hdrcharset=binary** is also in effect for that file.)

The −**k** option was added to address international concerns about the dangers involved in the character set transformations of −**e** (if the target character set were different from the source, the filenames might be transformed into names matching existing files) and also was made more general to protect files transferred between file systems with different {NAME_MAX} values (truncating a filename on a smaller system might also inadvertently overwrite existing files). As stated, it prevents any overwriting, even if the target file is older than the source. This version adds more granularity of options to solve this problem by introducing the −**oinvalid=option** ‡′ specifically the **UTF-8** and **binary** actions. (Note that an existing file is still subject to overwriting in this case. The −**k** option closes that loophole.)

Some of the file characteristics referenced in this volume of POSIX.1-2017 might not be supported by some archive formats. For example, neither the **tar** nor **cpio** formats contain the file access time. For this reason, the `e` specification character has been provided, intended to cause all file characteristics specified in the archive to be retained.

It is required that extracted directories, by default, have their access and modification times and permissions set to the values specified in the archive. This has obvious problems in that the directories are almost certainly modified after being extracted and that directory permissions may not permit file creation. One possible solution is to create directories with the mode specified in the archive, as modified by the *umask* of the user, with sufficient permissions to allow file creation. After all files have been extracted, *pax* would then reset the access and modification times and permissions as necessary.

The list-mode formatting description borrows heavily from the one defined by the *printf* utility. However, since there is no separate operand list to get conversion arguments, the format was extended to allow specifying the name of the conversion argument as part of the conversion specification.

The `T` conversion specifier allows time fields to be displayed in any of the date formats. Unlike the *ls* utility, *pax* does not adjust the format when the date is less than six months in the past. This makes parsing the output more predictable.

The `D` conversion specifier handles the ability to display the major/minor or file size, as with *ls*, by using `%-8(`*size*`)D`.

The `L` conversion specifier handles the *ls* display for symbolic links.

Conversion specifiers were added to generate existing known types used for *ls*.

pax Interchange Format

The new POSIX data interchange format was developed primarily to satisfy international concerns that the **ustar** and **cpio** formats did not provide for file, user, and group names encoded in characters outside a subset of the ISO/IEC 646:1991 standard. The standard developers realized that this new POSIX data interchange format should be very extensible because there were other requirements they foresaw in the near future:

- Support international character encodings and locale information
- Support security information (ACLs, and so on)
- Support future file types, such as realtime or contiguous files
- Include data areas for implementation use
- Support systems with words larger than 32 bits and timers with subsecond granularity

The following were not goals for this format because these are better handled by separate utilities or are inappropriate for a portable format:

- Encryption
- Compression
- Data translation between locales and codesets
- *inode* storage

The format chosen to support the goals is an extension of the **ustar** format. Of the two formats previously available, only the **ustar** format was selected for extensions because:

It was easier to extend in an upwards-compatible way. It offered version flags and header block type fields with room for future standardization. The **cpio** format, while possessing a more flexible file naming methodology, could not be extended without breaking some theoretical implementation or using a dummy filename that could be a legitimate filename.

Industry experience since the original ``*tar* wars'' fought in developing the ISO POSIX-1 standard has clearly been in favor of the **ustar** format, which is generally the default output format selected for *pax* implementations on new systems.

The new format was designed with one additional goal in mind: reasonable behavior when an older *tar* or *pax* utility happened to read an archive. Since the POSIX.1-1990 standard mandated that a ``format-reading utility'' had to treat unrecognized *typeflag* values as regular files, this allowed the format to include all the extended information in a pseudo-regular file that preceded each real file. An option is given that allows the archive creator to set up reasonable names for these files on the older systems. Also, the normative text suggests that reasonable file access values be used for this **ustar** header block. Making these header files inaccessible for convenient reading and deleting would not be reasonable. File permissions of 600 or 700 are suggested.

The **ustar** *typeflag* field was used to accommodate the additional functionality of the new format rather than magic or version because the POSIX.1-1990 standard (and, by reference, the previous version of *pax*), mandated the behavior of the format-reading utility when it encountered an unknown *typeflag*, but was silent about the other two fields.

Early proposals for the first version of this standard contained a proposed archive format that was based on compatibility with the standard for tape files (ISO 1001, similar to the format used historically on many mainframes and minicomputers). This format was overly complex and required considerable overhead in volume and header records. Furthermore, the standard developers felt that it would not be acceptable to the community of POSIX developers, so it was later changed to be a format more closely related to historical practice on POSIX systems.

The prefix and name split of pathnames in **ustar** was replaced by the single path extended header record for simplicity.

The concept of a global extended header (*typeflag* **g**) was controversial. If this were applied to an archive being recorded on magnetic tape, a few unreadable blocks at the beginning of the tape could be a serious problem; a utility attempting to extract as many files as possible from a damaged archive could lose a large percentage of file header information in this case. However, if the archive were on a reliable medium, such as a CD-ROM, the global extended header offers considerable potential size reductions by eliminating redundant information. Thus, the text warns against using the global method for unreliable media and provides a method for implanting global information in the extended header for each file, rather than in the *typeflag* **g** records.

No facility for data translation or filtering on a per-file basis is included because the standard developers could not invent an interface that would allow this in an efficient manner. If a filter, such as encryption or compression, is to be applied to all the files, it is more efficient to apply the filter to the entire archive as a single file. The standard developers considered interfaces that would invoke a shell script for each file going into or out of the archive, but the system overhead in this approach was considered to be too high.

One such approach would be to have **filter=** records that give a pathname for an executable. When the program is invoked, the file and archive would be open for standard input/output and all the header fields would be available as environment variables or command-line arguments. The standard developers did discuss such schemes, but they were omitted from POSIX.1-2017 due to concerns about excessive overhead. Also, the program itself would need to

be in the archive if it were to be used portably.

There is currently no portable means of identifying the character set(s) used for a file in the file system. Therefore, *pax* has not been given a mechanism to generate charset records automatically. The only portable means of doing this is for the user to write the archive using the **−ocharset=string** command line option. This assumes that all of the files in the archive use the same encoding. The ``implementation-defined'' text is included to allow for a system that can identify the encodings used for each of its files.

The table of standards that accompanies the charset record description is acknowledged to be very limited. Only a limited number of character set standards is reasonable for maximal interchange. Any character set is, of course, possible by prior agreement. It was suggested that EBCDIC be listed, but it was omitted because it is not defined by a formal standard. Formal standards, and then only those with reasonably large followings, can be included here, simply as a matter of practicality. The <*value*>s represent names of officially registered character sets in the format required by the ISO 2375: 1985 standard.

The normal <comma> or <blank>-separated list rules are not followed in the case of keyword options to allow ease of argument parsing for *getopts*.

Further information on character encodings is in pax Archive Character Set Encoding/Decoding (on page 3102).

The standard developers have reserved keyword name space for vendor extensions. It is suggested that the format to be used is:

```
VENDOR.keyword
```

where *VENDOR* is the name of the vendor or organization in all uppercase letters. It is further suggested that the keyword following the <period> be named differently than any of the standard keywords so that it could be used for future standardization, if appropriate, by omitting the *VENDOR* prefix.

The <*length*> field in the extended header record was included to make it simpler to step through the records, even if a record contains an unknown format (to a particular *pax*) with complex interactions of special characters. It also provides a minor integrity checkpoint within the records to aid a program attempting to recover files from a damaged archive.

There are no extended header versions of the *devmajor* and *devminor* fields because the unspecified format **ustar** header field should be sufficient. If they are not, vendor-specific extended keywords (such as *VENDOR.devmajor*) should be used.

Device and *i*-number labeling of files was not adopted from *cpio*; files are interchanged strictly on a symbolic name basis, as in **ustar**.

Just as with the **ustar** format descriptions, the new format makes no special arrangements for multi-volume archives. Each of the *pax* archive types is assumed to be inside a single POSIX file and splitting that file over multiple volumes (diskettes, tape cartridges, and so on), processing their labels, and mounting each in the proper sequence are considered to be implementation details that cannot be described portably.

The **pax** format is intended for interchange, not only for backup on a single (family of) systems. It is not as densely packed as might be possible for backup:

- It contains information as coded characters that could be coded in binary.
- It identifies extended records with name fields that could be omitted in favor of a fixed-field layout.

It translates names into a portable character set and identifies locale-related information, both of which are probably unnecessary for backup.

The requirements on restoring from an archive are slightly different from the historical wording, allowing for non-monolithic privilege to bring forward as much as possible. In particular, attributes such as ``high performance file'' might be broadly but not universally granted while set-user-ID or *chown*() might be much more restricted. There is no implication in POSIX.1-2017 that the security information be honored after it is restored to the file hierarchy, in spite of what might be improperly inferred by the silence on that topic. That is a topic for another standard.

Links are recorded in the fashion described here because a link can be to any file type. It is desirable in general to be able to restore part of an archive selectively and restore all of those files completely. If the data is not associated with each link, it is not possible to do this. However, the data associated with a file can be large, and when selective restoration is not needed, this can be a significant burden. The archive is structured so that files that have no associated data can always be restored by the name of any link name of any link, and the user may choose whether data is recorded with each instance of a file that contains data. The format permits mixing of both types of links in a single archive; this can be done for special needs, and *pax* is expected to interpret such archives on input properly, despite the fact that there is no *pax* option that would force this mixed case on output. (When **−o linkdata** is used, the output must contain the duplicate data, but the implementation is free to include it or omit it when **−o linkdata** is not used.)

The time values are included as extended header records for those implementations needing more than the eleven octal digits allowed by the **ustar** format. Portable file timestamps cannot be negative. If *pax* encounters a file with a negative timestamp in **copy** or **write** mode, it can reject the file, substitute a non-negative timestamp, or generate a non-portable timestamp with a leading `'-'`. Even though some implementations can support finer file-time granularities than seconds, the normative text requires support only for seconds since the Epoch because the ISO POSIX-1 standard states them that way. The **ustar** format includes only *mtime*; the new format adds *atime* and *ctime* for symmetry. The *atime* access time restored to the file system will be affected by the **−p a** and **−p e** options. The *ctime* creation time (actually *inode* modification time) is described with appropriate privileges so that it can be ignored when writing to the file system. POSIX does not provide a portable means to change file creation time. Nothing is intended to prevent a non-portable implementation of *pax* from restoring the value.

The *gid*, *size*, and *uid* extended header records were included to allow expansion beyond the sizes specified in the regular *tar* header. New file system architectures are emerging that will exhaust the 12-digit size field. There are probably not many systems requiring more than 8 digits for user and group IDs, but the extended header values were included for completeness, allowing overrides for all of the decimal values in the *tar* header.

The standard developers intended to describe the effective results of *pax* with regard to file ownerships and permissions; implementations are not restricted in timing or sequencing the restoration of such, provided the results are as specified.

Much of the text describing the extended headers refers to use in ``**write** or **copy** modes''. The **copy** mode references are due to the normative text: ``The effect of the copy shall be as if the copied files were written to an archive file and then subsequently extracted ...''. There is certainly no way to test whether *pax* is actually generating the extended headers in **copy** mode, but the effects must be as if it had.

pax Archive Character Set Encoding/Decoding

There is a need to exchange archives of files between systems of different native codesets. Filenames, group names, and user names must be preserved to the fullest extent possible when an archive is read on the receiving platform. Translation of the contents of files is not within the scope of the *pax* utility.

There will also be the need to represent characters that are not available on the receiving platform. These unsupported characters cannot be automatically folded to the local set of characters due to the chance of collisions. This could result in overwriting previous extracted files from the archive or pre-existing files on the system.

For these reasons, the codeset used to represent characters within the extended header records of the *pax* archive must be sufficiently rich to handle all commonly used character sets. The fields requiring translation include, at a minimum, filenames, user names, group names, and link pathnames. Implementations may wish to have localized extended keywords that use non-portable characters.

The standard developers considered the following options:

> The archive creator specifies the well-defined name of the source codeset. The receiver must then recognize the codeset name and perform the appropriate translations to the destination codeset.
>
> The archive creator includes within the archive the character mapping table for the source codeset used to encode extended header records. The receiver must then read the character mapping table and perform the appropriate translations to the destination codeset.
>
> The archive creator translates the extended header records in the source codeset into a canonical form. The receiver must then perform the appropriate translations to the destination codeset.

The approach that incorporates the name of the source codeset poses the problem of codeset name registration, and makes the archive useless to *pax* archive decoders that do not recognize that codeset.

Because parts of an archive may be corrupted, the standard developers felt that including the character map of the source codeset was too fragile. The loss of this one key component could result in making the entire archive useless. (The difference between this and the global extended header decision was that the latter has a workaround—duplicating extended header records on unreliable media—but this would be too burdensome for large character set maps.)

Both of the above approaches also put an undue burden on the *pax* archive receiver to handle the cross-product of all source and destination codesets.

To simplify the translation from the source codeset to the canonical form and from the canonical form to the destination codeset, the standard developers decided that the internal representation should be a stateless encoding. A stateless encoding is one where each codepoint has the same meaning, without regard to the decoder being in a specific state. An example of a stateful encoding would be the Japanese Shift-JIS; an example of a stateless encoding would be the ISO/IEC 646:1991 standard (equivalent to 7-bit ASCII).

For these reasons, the standard developers decided to adopt a canonical format for the representation of file information strings. The obvious, well-endorsed candidate is the ISO/IEC 10646-1:2000 standard (based in part on Unicode), which can be used to represent the characters of virtually all standardized character sets. The standard developers initially agreed upon using UCS2 (16-bit Unicode) as the internal representation. This repertoire of characters

103679 provides a sufficiently rich set to represent all commonly-used codesets.

103680 However, the standard developers found that the 16-bit Unicode representation had some
103681 problems. It forced the issue of standardizing byte ordering. The 2-byte length of each character
103682 made the extended header records twice as long for the case of strings coded entirely from
103683 historical 7-bit ASCII. For these reasons, the standard developers chose the UTF-8 defined in the
103684 ISO/IEC 10646-1: 2000 standard. This multi-byte representation encodes UCS2 or UCS4
103685 characters reliably and deterministically, eliminating the need for a canonical byte ordering. In
103686 addition, NUL octets and other characters possibly confusing to POSIX file systems do not
103687 appear, except to represent themselves. It was realized that certain national codesets take up
103688 more space after the encoding, due to their placement within the UCS range; it was felt that the
103689 usefulness of the encoding of the names outweighs the disadvantage of size increase for file,
103690 user, and group names.

103691 The encoding of UTF-8 is as follows:

```
103692 UCS4 Hex Encoding  UTF-8 Binary Encoding

103693 00000000-0000007F  0xxxxxxx
103694 00000080-000007FF  110xxxxx 10xxxxxx
103695 00000800-0000FFFF  1110xxxx 10xxxxxx 10xxxxxx
103696 00010000-001FFFFF  11110xxx 10xxxxxx 10xxxxxx 10xxxxxx
103697 00200000-03FFFFFF  111110xx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
103698 04000000-7FFFFFFF  1111110x 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
```

103699 where each `'x'` represents a bit value from the character being translated.

103700 **ustar Interchange Format**

103701 The description of the **ustar** format reflects numerous enhancements over pre-1988 versions of
103702 the historical *tar* utility. The goal of these changes was not only to provide the functional
103703 enhancements desired, but also to retain compatibility between new and old versions. This
103704 compatibility has been retained. Archives written using the old archive format are compatible
103705 with the new format.

103706 Implementors should be aware that the previous file format did not include a mechanism to
103707 archive directory type files. For this reason, the convention of using a filename ending with
103708 <slash> was adopted to specify a directory on the archive.

103709 The total size of the *name* and *prefix* fields have been set to meet the minimum requirements for
103710 {PATH_MAX}. If a pathname will fit within the *name* field, it is recommended that the pathname
103711 be stored there without the use of the *prefix* field. Although the name field is known to be too
103712 small to contain {PATH_MAX} characters, the value was not changed in this version of the
103713 archive file format to retain backwards-compatibility, and instead the prefix was introduced.
103714 Also, because of the earlier version of the format, there is no way to remove the restriction on the
103715 *linkname* field being limited in size to just that of the *name* field.

103716 The *size* field is required to be meaningful in all implementation extensions, although it could be
103717 zero. This is required so that the data blocks can always be properly counted.

103718 It is suggested that if device special files need to be represented that cannot be represented in the
103719 standard format, that one of the extension types (**A**-**Z**) be used, and that the additional
103720 information for the special file be represented as data and be reflected in the *size* field.

103721 Attempting to restore a special file type, where it is converted to ordinary data and conflicts with
103722 an existing filename, need not be specially detected by the utility. If run as an ordinary user, *pax*
103723 should not be able to overwrite the entries in, for example, **/dev** in any case (whether the file is

converted to another type or not). If run as a privileged user, it should be able to do so, and it would be considered a bug if it did not. The same is true of ordinary data files and similarly named special files; it is impossible to anticipate the needs of the user (who could really intend to overwrite the file), so the behavior should be predictable (and thus regular) and rely on the protection system as required.

The value 7 in the *typeflag* field is intended to define how contiguous files can be stored in a **ustar** archive. POSIX.1-2017 does not require the contiguous file extension, but does define a standard way of archiving such files so that all conforming systems can interpret these file types in a meaningful and consistent manner. On a system that does not support extended file types, the *pax* utility should do the best it can with the file and go on to the next.

The file protection modes are those conventionally used by the *ls* utility. This is extended beyond the usage in the ISO POSIX-2 standard to support the ``shared text'' or ``sticky'' bit. It is intended that the conformance document should not document anything beyond the existence of and support of such a mode. Further extensions are expected to these bits, particularly with overloading the set-user-ID and set-group-ID flags.

cpio Interchange Format

The reference to appropriate privileges in the **cpio** format refers to an error on standard output; the **ustar** format does not make comparable statements.

The model for this format was the historical System V *cpio*−**c** data interchange format. This model documents the portable version of the **cpio** format and not the binary version. It has the flexibility to transfer data of any type described within POSIX.1-2017, yet is extensible to transfer data types specific to extensions beyond POSIX.1-2017 (for example, contiguous files). Because it describes existing practice, there is no question of maintaining upwards-compatibility.

cpio Header

There has been some concern that the size of the *c_ino* field of the header is too small to handle those systems that have very large *inode* numbers. However, the *c_ino* field in the header is used strictly as a hard-link resolution mechanism for archives. It is not necessarily the same value as the *inode* number of the file in the location from which that file is extracted.

The name *c_magic* is based on historical usage.

cpio Filename

For most historical implementations of the *cpio* utility, {PATH_MAX} octets can be used to describe the pathname without the addition of any other header fields (the NUL character would be included in this count). {PATH_MAX} is the minimum value for pathname size, documented as 256 bytes. However, an implementation may use *c_namesize* to determine the exact length of the pathname. With the current description of the **<cpio.h>** header, this pathname size can be as large as a number that is described in six octal digits.

Two values are documented under the *c_mode* field values to provide for extensibility for known file types:

0110 000 Reserved for contiguous files. The implementation may treat the rest of the information for this archive like a regular file. If this file type is undefined, the implementation may create the file as a regular file.

This provides for extensibility of the **cpio** format while allowing for the ability to read old archives. Files of an unknown type may be read as ``regular files'' on some implementations. On a system that does not support extended file types, the *pax* utility should do the best it can with

the file and go on to the next.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

A note is added to the APPLICATION USAGE indicating that the **cpio** and **tar** formats can only support files up to 8 gigabytes in size.

Issue 6

The *pax* utility is aligned with the IEEE P1003.2b draft standard:

Support has been added for symbolic links in the options and interchange formats.

A new format has been devised, based on extensions to **ustar**.

References to the ``extended'' **tar** and **cpio** formats derived from the POSIX.1-1990 standard have been changed to remove the ``extended'' adjective because this could cause confusion with the extended **tar** header added in this version. (All references to **tar** are actually to **ustar**.)

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #168 is applied, clarifying that *mkdir*( ) and *mkfifo*( ) calls can ignore an [EEXIST] error when extracting an archive.

IEEE PASC Interpretation 1003.2 #180 is applied, clarifying how extracted files are created when in **read** mode.

IEEE PASC Interpretation 1003.2 #181 is applied, clarifying the description of the **−t** option.

IEEE PASC Interpretation 1003.2 #195 is applied.

IEEE PASC Interpretation 1003.2 #206 is applied, clarifying the handling of links for the **−H**, **−L**, and **−l** options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/35 is applied, adding the process ID of the *pax* process into certain fields. This change provides a method for the implementation to ensure that different instances of *pax* extracting a file named **/a/b/foo** will not collide when processing the extended header information associated with **foo**.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/36 is applied, changing **−x B** to **−x** *pax* in the OPTIONS section.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/20 is applied, updating the SYNOPSIS to be consistent with the normative text.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/21 is applied, updating the DESCRIPTION to describe the behavior when files to be linked are symbolic links and the system is not capable of making hard links to symbolic links.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/22 is applied, updating the OPTIONS section to describe the behavior for how multiple −**odelete=pattern** options are to be handled.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/23 is applied, updating the **write** option within the OPTIONS section.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/24 is applied, adding a paragraph into the OPTIONS section that states that specifying more than one of the mutually-exclusive options (−**H** and −**L**) is not considered an error and that the last option specified will determine the behavior of the utility.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/25 is applied, removing the *ctime* paragraph within the EXTENDED DESCRIPTION. There is a contradiction in the definition of the *ctime* keyword for the *pax* extended header, in that the *st_ctime* member of the **stat** structure does not refer to a file creation time. No field in the standard **stat** structure from **<sys/stat.h>** includes a file creation time.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/26 is applied, making it clear that *typeflag* 1 (**ustar** Interchange Format) applies not only to files that are hard-linked, but also to files that are aliased via symbolic links.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/27 is applied, clarifying the *cpio c_nlink* field.

Issue 7

Austin Group Interpretations 1003.1-2001 #011, #036, #086, and #109 are applied.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

SD5-XCU-ERN-2 is applied, making −**c** and −**n** mutually-exclusive in the SYNOPSIS.

SD5-XCU-ERN-3 is applied, revising the default behavior of −**H** and −**L**.

SD5-XCU-ERN-5, SD5-XCU-ERN-6, SD5-XCU-ERN-7, SD5-XCU-ERN-60 are applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *pax* utility is no longer allowed to create separate identical symbolic links when extracting linked symbolic links from an archive.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0128 [260], XCU/TC1-2008/0129 [261], XCU/TC1-2008/0130 [261], XCU/TC1-2008/0131 [313], and XCU/TC1-2008/0132 [233] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0152 [886], XCU/TC2-2008/0153 [814], XCU/TC2-2008/0154 [886], and XCU/TC2-2008/0155 [707] are applied.

NAME

pr ‡'print files

SYNOPSIS

```
pr [+page] [−column] [−adFmrt] [−e[char][gap]] [−h header] [−i[char][gap]]
    [−l lines] [−n[char][width]] [−o offset] [−s[char]] [−w width] [ −fp]
    [file...]
```

XSI

DESCRIPTION

The *pr* utility is a printing and pagination filter. If multiple input files are specified, each shall be read, formatted, and written to standard output. By default, the input shall be separated into 66-line pages, each with:

A 5-line header that includes the page number, date, time, and the pathname of the file

A 5-line trailer consisting of blank lines

If standard output is associated with a terminal, diagnostic messages shall be deferred until the *pr* utility has completed processing.

When options specifying multi-column output are specified, output text columns shall be of equal width; input lines that do not fit into a text column shall be truncated. By default, text columns shall be separated with at least one <blank>.

OPTIONS

The *pr* utility shall conform to XBD Section 12.2 (on page 216), except that: the *page* option has a `'+'` delimiter; *page* and *column* can be multi-digit numbers; some of the option-arguments are optional; and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the **−s** option does not allow the option letter to be separated from its argument, and the options **−e**, **−i**, and **−n** require that both arguments, if present, not be separated from the option letter.

The following options shall be supported. In the following option descriptions, *column*, *lines*, *offset*, *page*, and *width* are positive decimal integers; *gap* is a non-negative decimal integer.

+*page* Begin output at page number *page* of the formatted input.

−*column* Produce multi-column output that is arranged in *column* columns (the default shall be 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with **−m**. The options **−e** and **−i** shall be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column shall never exceed the length of the page (see the **−l** option). When used with **−t**, use the minimum number of lines to write the output.

−a Modify the effect of the **−***column* option so that the columns are filled across the page in a round-robin order (for example, when *column* is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so on).

−d Produce output that is double-spaced; append an extra <newline> following every <newline> found in the input.

−e[*char*][*gap*]
Expand each input <tab> to the next greater column position specified by the formula *n***gap*+1, where *n* is an integer > 0. If *gap* is zero or is omitted, it shall default to 8. All <tab> characters in the input shall be expanded into the appropriate number of <space> characters. If any non-digit character, *char*, is specified, it shall be used as the input <tab>. If the first character of the **−e** option-

argument is a digit, the entire option-argument shall be assumed to be *gap*.

XSI **−f** Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline> characters. Pause before beginning the first page if the standard output is associated with a terminal.

−F Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline> characters.

−h *header* Use the string *header* to replace the contents of the *file* operand in the page header.

−i[*char***][***gap***]** In output, replace <space> characters with <tab> characters wherever one or more adjacent <space> characters reach column positions *gap*+1, 2* *gap*+1, 3* *gap*+1, and so on. If *gap* is zero or is omitted, default tab settings at every eighth column position shall be assumed. If any non-digit character, *char*, is specified, it shall be used as the output <tab>. If the first character of the **−i** option-argument is a digit, the entire option-argument shall be assumed to be *gap*.

−l *lines* Override the 66-line default and reset the page length to *lines*. If *lines* is not greater than the sum of both the header and trailer depths (in lines), the *pr* utility shall suppress both the header and trailer, as if the **−t** option were in effect.

−m Merge files. Standard output shall be formatted so the *pr* utility writes one line from each file specified by a *file* operand, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations shall support merging of at least nine *file* operands.

−n[*char***][***width***]**
Provide *width*-digit line numbering (default for *width* shall be 5). The number shall occupy the first *width* column positions of each text column of default output or each line of **−m** output. If *char* (any non-digit character) is given, it shall be appended to the line number to separate it from whatever follows (default for *char* is a <tab>).

−o *offset* Each line of output shall be preceded by offset <space> characters. If the **−o** option is not specified, the default offset shall be zero. The space taken is in addition to the output line width (see the **−w** option below).

−p Pause before beginning each page if the standard output is directed to a terminal (*pr* shall write an <alert> to standard error and wait for a <carriage-return> to be read on **/dev/tty**).

−r Write no diagnostic reports on failure to open files.

−s[*char***]** Separate text columns by the single character *char* instead of by the appropriate number of <space> characters (default for *char* shall be <tab>).

−t Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.

−w *width* Set the width of the line to *width* column positions for multiple text-column output only. If the **−w** option is not specified and the **−s** option is not specified, the default width shall be 72. If the **−w** option is not specified and the **−s** option is specified, the default width shall be 512.

For single column output, input lines shall not be truncated.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be written. If no *file* operands are specified, or if a *file* operand is `'-'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'-'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

The file **/dev/tty** shall be used to read responses required by the **−p** option.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pr*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as printable (character class **print**). Non-printable characters are still written to standard output, but are not counted for the purpose for column-width and line-length calculations.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format of the date and time for use in writing header lines.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone used to calculate date and time strings written in header lines. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

If *pr* receives an interrupt while writing to a terminal, it shall flush all accumulated error messages to the screen before terminating.

STDOUT

The *pr* utility output shall be a paginated version of the original file (or files). This pagination shall be accomplished using either <form-feed> characters or a sequence of <newline> characters, as controlled by the **−F** or **−f** option. Page headers shall be generated unless the **−t** option is specified. The page headers shall be of the form:

XSI

```
"\n\n%s %s Page %d\n\n\n", <output of date>, <file>, <page number>
```

In the POSIX locale, the <*output of date*> field, representing the date and time of last modification of the input file (or the current date and time if the input file is standard input), shall be equivalent to the output of the following command as it would appear if executed at the given time:

```
date "+%b %e %H:%M %Y"
```

without the trailing <newline>, if the page being written is from standard input. If the page being written is not from standard input, in the POSIX locale, the same format shall be used, but the time used shall be the modification time of the file corresponding to *file* instead of the current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the standard input is used instead of a *file* operand, the <*file*> field shall be replaced by a null string.

If the **−h** option is specified, the <*file*> field shall be replaced by the *header* argument.

STDERR

The standard error shall be used for diagnostic messages and for alerting the terminal when **−p** is specified.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

A conforming application must protect its first operand, if it starts with a <plus-sign>, by preceding it with the `"−−"` argument that denotes the end of the options. For example, *pr+x* could be interpreted as an invalid page number or a *file* operand.

EXAMPLES

1. Print a numbered list of all files in the current directory:

   ```
   ls −a | pr −n −h "Files in $(pwd)."
   ```

2. Print **file1** and **file2** as a double-spaced, three-column listing headed by ``file list'':

   ```
   pr −3d −h "file list" file1 file2
   ```

3. Write **file1** on **file2**, expanding tabs to columns 10, 19, 28, . . .:

   ```
   pr −e9 −t <file1 >file2
   ```

RATIONALE

This utility is one of those that does not follow the Utility Syntax Guidelines because of its historical origins. The standard developers could have added new options that obeyed the guidelines (and marked the old options obsolescent) or devised an entirely new utility; there are examples of both actions in this volume of POSIX.1-2017. Because of its widespread use by historical applications, the standard developers decided to exempt this version of *pr* from many of the guidelines.

Implementations are required to accept option-arguments to the **−h**, **−l**, **−o**, and **−w** options whether presented as part of the same argument or as a separate argument to *pr*, as suggested by the Utility Syntax Guidelines. The **−n** and **−s** options, however, are specified as in historical

practice because they are frequently specified without their optional arguments. If a <blank> were allowed before the option-argument in these cases, a *file* operand could mistakenly be interpreted as an option-argument in historical applications.

The text about the minimum number of lines in multi-column output was included to ensure that a best effort is made in balancing the length of the columns. There are known historical implementations in which, for example, 60-line files are listed by *pr* −2 as one column of 56 lines and a second of 4. Although this is not a problem when a full page with headers and trailers is produced, it would be relatively useless when used with −**t**.

Historical implementations of the *pr* utility have differed in the action taken for the −**f** option. BSD uses it as described here for the −**F** option; System V uses it to change trailing <newline> characters on each page to a <form-feed> and, if standard output is a TTY device, sends an <alert> to standard error and reads a line from **/dev/tty** before the first page. There were strong arguments from both sides of this issue concerning historical practice and as a result the −**F** option was added. XSI-conformant systems support the System V historical actions for the −**f** option.

The <*output of date*> field in the −**l** format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of POSIX.1-2017, as the appropriate vehicle is a message catalog; that is, the format should be specified as a ``message''.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The −**p** option is added.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

PASC Interpretation 1003.2-92 #151 (SD5-XCU-ERN-44) is applied.

Austin Group Interpretation 1003.1-2001 #093 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

104051 **NAME**

104052 printf ‡'write formatted output

104053 **SYNOPSIS**

104054 `printf format [argument...]`

104055 **DESCRIPTION**

104056 The *printf* utility shall write formatted operands to the standard output. The *argument* operands
104057 shall be formatted under control of the *format* operand.

104058 **OPTIONS**

104059 None.

104060 **OPERANDS**

104061 The following operands shall be supported:

104062 *format* A string describing the format to use to write the remaining operands. See the
104063 EXTENDED DESCRIPTION section.

104064 *argument* The strings to be written to standard output, under the control of *format*. See the
104065 EXTENDED DESCRIPTION section.

104066 **STDIN**

104067 Not used.

104068 **INPUT FILES**

104069 None.

104070 **ENVIRONMENT VARIABLES**

104071 The following environment variables shall affect the execution of *printf*:

104072 *LANG* Provide a default value for the internationalization variables that are unset or null.
104073 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
104074 used to determine the values of locale categories.)

104075 *LC_ALL* If set to a non-empty string value, override the values of all the other
104076 internationalization variables.

104077 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
104078 characters (for example, single-byte as opposed to multi-byte characters in
104079 arguments).

104080 *LC_MESSAGES*

104081 Determine the locale that should be used to affect the format and contents of
104082 diagnostic messages written to standard error.

104083 *LC_NUMERIC*

104084 Determine the locale for numeric formatting. It shall affect the format of numbers
104085 written using the `e`, `E`, `f`, `g`, and `G` conversion specifier characters (if supported).

104086 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

104087 **ASYNCHRONOUS EVENTS**

104088 Default.

104089 **STDOUT**

104090 See the EXTENDED DESCRIPTION section.

104091 **STDERR**

104092 The standard error shall be used only for diagnostic messages.

104093 **OUTPUT FILES**

104094 None.

104095 **EXTENDED DESCRIPTION**

104096 The *format* operand shall be used as the *format* string described in XBD Chapter 5 (on page 121)
104097 with the following exceptions:

104098 1. A <space> in the format string, in any context other than a flag of a conversion
104099 specification, shall be treated as an ordinary character that is copied to the output.

104100 2. A `'Δ'` character in the format string shall be treated as a `'Δ'` character, not as a <space>.

104101 3. In addition to the escape sequences shown in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`,
104102 `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`), `"\ddd"`, where *ddd* is a one, two, or three-digit
104103 octal number, shall be written as a byte with the numeric value specified by the octal
104104 number.

104105 4. The implementation shall not precede or follow output from the `d` or `u` conversion
104106 specifiers with <blank> characters not specified by the *format* operand.

104107 5. The implementation shall not precede output from the `o` conversion specifier with zeros
104108 not specified by the *format* operand.

104109 6. The `a`, `A`, `e`, `E`, `f`, `F`, `g`, and `G` conversion specifiers need not be supported.

104110 7. An additional conversion specifier character, `b`, shall be supported as follows. The
104111 argument shall be taken to be a string that can contain <backslash>-escape sequences.
104112 The following <backslash>-escape sequences shall be supported:

104113 ‡ĸeTescape sequences listed in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`,
104114 `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`), which shall be converted to the characters they
104115 represent

104116 ‡"`\0ddd"`, where *ddd* is a zero, one, two, or three-digit octal number that shall be
104117 converted to a byte with the numeric value specified by the octal number

104118 ‡'`\c'`, which shall not be written and shall cause *printf* to ignore any remaining
104119 characters in the string operand containing it, any remaining string operands, and
104120 any additional characters in the *format* operand

104121 The interpretation of a <backslash> followed by any other sequence of characters is
104122 unspecified.

104123 Bytes from the converted string shall be written until the end of the string or the number
104124 of bytes indicated by the precision specification is reached. If the precision is omitted, it
104125 shall be taken to be infinite, so all bytes up to the end of the converted string shall be
104126 written.

104127 8. For each conversion specification that consumes an argument, the next *argument* operand
104128 shall be evaluated and converted to the appropriate type for the conversion as specified
104129 below.

104130 9. The *format* operand shall be reused as often as necessary to satisfy the *argument* operands.
104131 Any extra `b`, `c`, or `s` conversion specifiers shall be evaluated as if a null string argument
104132 were supplied; other extra conversion specifications shall be evaluated as if a zero
104133 argument were supplied. If the *format* operand contains no conversion specifications and
104134 *argument* operands are present, the results are unspecified.

10. If a character sequence in the *format* operand begins with a '%' character, but does not form a valid conversion specification, the behavior is unspecified.

11. The argument to the c conversion specifier can be a string containing zero or more bytes. If it contains one or more bytes, the first byte shall be written and any additional bytes shall be ignored. If the argument is an empty string, it is unspecified whether nothing is written or a null byte is written.

The *argument* operands shall be treated as strings if the corresponding conversion specifier is b, c, or s, and shall be evaluated as if by the *strtod*() function if the corresponding conversion specifier is a, A, e, E, f, F, g, or G. Otherwise, they shall be evaluated as unsuffixed C integer constants, as described by the ISO C standard, with the following extensions:

A leading <plus-sign> or <hyphen-minus> shall be allowed.

If the leading character is a single-quote or double-quote, the value shall be the numeric value in the underlying codeset of the character following the single-quote or double-quote.

Suffixed integer constants may be allowed.

If an *argument* operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message shall be written to standard error and the utility shall not exit with a zero exit status, but shall continue processing any remaining operands and shall write the value accumulated at the time the error was detected to standard output.

It shall not be considered an error if an *argument* operand is not completely used for a b, c, or s conversion.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The floating-point formatting conversion specifications of *printf*() are not required because all arithmetic in the shell is integer arithmetic. The *awk* utility performs floating-point calculations and provides its own **printf** function. The *bc* utility can perform arbitrary-precision floating-point arithmetic, but does not provide extensive formatting capabilities. (This *printf* utility cannot really be used to format *bc* output; it does not support arbitrary precision.) Implementations are encouraged to support the floating-point conversions as an extension.

Note that this *printf* utility, like the *printf*() function defined in the System Interfaces volume of POSIX.1-2017 on which it is based, makes no special provision for dealing with multi-byte characters when using the %c conversion specification or when a precision is specified in a %b or %s conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

No provision is made in this volume of POSIX.1-2017 which allows field widths and precisions to be specified as '*' since the '*' can be replaced directly in the *format* operand using shell variable substitution. Implementations can also provide this feature as an extension if they so choose.

Hexadecimal character constants as defined in the ISO C standard are not recognized in the *format* operand because there is no consistent way to detect the end of the constant. Octal character constants are limited to, at most, three octal digits, but hexadecimal character constants are only terminated by a non-hex-digit character. In the ISO C standard, the `"##"` concatenation operator can be used to terminate a constant and follow it with a hexadecimal character to be written. In the shell, concatenation occurs before the *printf* utility has a chance to parse the end of the hexadecimal constant.

The `%b` conversion specification is not part of the ISO C standard; it has been added here as a portable way to process <backslash>-escapes expanded in string operands as provided by the *echo* utility. See also the APPLICATION USAGE section of *echo* (on page 2674) for ways to use *printf* as a replacement for all of the traditional versions of the *echo* utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the *printf* utility is required to report an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion shall be reported as errors.

EXAMPLES

To alert the user and then print and read a series of prompts:

```
printf "\aPlease fill in the following: \nName: "
read name
printf "Phone number: "
read phone
```

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single <tab>. The percentage is written to one decimal place of accuracy:

```
while read right wrong ; do
    percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%s%%)\n" \
        $right $wrong $percent
done < database_file
```

The command:

```
printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
    1  21
  3214321
54321   0
```

Note that the *format* operand is used three times to print all of the given strings and that a `'0'` was supplied by *printf* to satisfy the last `%4d` conversion specification.

The *printf* utility is required to notify the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the *format* operand:

Argument	Standard Output	Diagnostic Output
`5a`	`5`	**`printf: "5a" not completely converted`**
`9999999999`	`2147483647`	**`printf: "9999999999" arithmetic overflow`**
`−9999999999`	`−2147483648`	**`printf: "−9999999999" arithmetic overflow`**
`ABC`	`0`	**`printf: "ABC" expected numeric value`**

The diagnostic message format is not specified, but these examples convey the type of information that should be reported. Note that the value shown on standard output is what would be expected as the return value from the *strtol*() function as defined in the System Interfaces volume of POSIX.1-2017. A similar correspondence exists between `%u` and *strtoul*() and `%e`, `%f`, and `%g` (if the implementation supports floating-point conversions) and *strtod*().

In a locale using the ISO/IEC 646: 1991 standard as the underlying codeset, the command:

```
printf "%d\n" 3 +3 −3 \'3 \"+3 "'−3"
```

produces:

3 Numeric value of constant 3

3 Numeric value of constant 3

–3 Numeric value of constant –3

51 Numeric value of the character `'3'` in the ISO/IEC 646: 1991 standard codeset

43 Numeric value of the character `'+'` in the ISO/IEC 646: 1991 standard codeset

45 Numeric value of the character `'−'` in the ISO/IEC 646: 1991 standard codeset

Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the **wchar_t** representation of the character as described in the System Interfaces volume of POSIX.1-2017.

RATIONALE

The *printf* utility was added to provide functionality that has historically been provided by *echo*. However, due to irreconcilable differences in the various versions of *echo* extant, the version has few special features, leaving those to this new *printf* utility, which is based on one in the Ninth Edition system.

The EXTENDED DESCRIPTION section almost exactly matches the *printf*() function in the ISO C standard, although it is described in terms of the file format notation in XBD Chapter 5 (on page 121).

Earlier versions of this standard specified that arguments for all conversions other than `b`, `c`, and `s` were evaluated in the same way (as C constants, but with stated exceptions). For implementations supporting the floating-point conversions it was not clear whether integer conversions need only accept integer constants and floating-point conversions need only accept floating-point constants, or whether both types of conversions should accept both types of constants. Also by not distinguishing between them, the requirement relating to a leading single-quote or double-quote applied to floating-point conversions even though this provided no useful functionality to applications that was not already available through the integer conversions. The current standard clarifies the situation by specifying that the arguments for floating-point conversions are evaluated as if by *strtod*(), and the arguments for integer conversions are evaluated as C integer constants, with the special treatment of leading single-quote and double-quote applying only to integer conversions.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 7

Austin Group Interpretations 1003.1-2001 #175 and #177 are applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0156 [727], XCU/TC2-2008/0157 [727,932], XCU/TC2-2008/0158 [584], and XCU/TC2-2008/0159 [727] are applied.

NAME

prs ‡'print an SCCS file(**DEVELOPMENT**)

SYNOPSIS

XSI
```
prs [-a] [-d dataspec] [-r[SID]] file...
prs [-e|-l] -c cutoff [-d dataspec] file...
prs [-e|-l] -r[SID] [-d dataspec] file...
```

DESCRIPTION

The *prs* utility shall write to standard output parts or all of an SCCS file in a user-supplied format.

OPTIONS

The *prs* utility shall conform to XBD Section 12.2 (on page 216), except that the **-r** option has an optional option-argument. This optional option-argument cannot be presented as a separate argument. The following options shall be supported:

-d *dataspec* Specify the output data specification. The *dataspec* shall be a string consisting of SCCS file *data keywords* (see Data Keywords, on page 3119) interspersed with optional user-supplied text.

-r[*SID*] Specify the SCCS identification string (SID) of a delta for which information is desired. If no *SID* option-argument is specified, the SID of the most recently created delta shall be assumed.

-e Request information for all deltas created earlier than and including the delta designated via the **-r** option or the date-time given by the **-c** option.

-l Request information for all deltas created later than and including the delta designated via the **-r** option or the date-time given by the **-c** option.

-c *cutoff* Indicate the *cutoff* date-time, in the form:

YY[*MM*[*DD*[*HH*[*MM*[*SS*]]]]]

For the *YY* component, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive.

Note: It is expected that in a future version of this standard the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)

No changes (deltas) to the SCCS file that were created after the specified *cutoff* date-time shall be included in the output. Units omitted from the date-time default to their maximum possible values; for example, **-c 7502** is equivalent to **-c 750228235959**.

-a Request writing of information for both removed ‡that is,*delta type=R* (see *rmdel*) ‡and existing ‡that is,*delta type=D*, ‡deltas. If the **-a** option is not specified, information for existing deltas only shall be provided.

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *prs* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

Any SCCS files displayed are files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *prs*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a text file whose format is dependent on the data keywords specified with the **−d** option.

Data Keywords

Data keywords specify which parts of an SCCS file shall be retrieved and output. All parts of an SCCS file have an associated data keyword. A data keyword may appear in a *dataspec* multiple times.

The information written by *prs* shall consist of:

1. The user-supplied text
2. Appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order of appearance in the *dataspec*

The format of a data keyword value shall either be simple (`'S'`), in which keyword substitution is direct, or multi-line (`'M'`).

User-supplied text shall be any text other than recognized data keywords. A <tab> shall be specified by `'\t'` and <newline> by `'\n'`. When the **−r** option is not specified, the default *dataspec* shall be:

```
:PN::\n\n
```

and the following *dataspec* shall be used for each selected delta:

```
:Dt:\t:DL:\nMRs:\n:MR:COMMENTS:\n:C:
```

*** The line statistics are capped at 99 999. For example, if 100 000 lines were unchanged in a certain revision, **:Lu:** shall produce the value 99 999.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. The following example:

   ```
   prs –d "User Names for :F: are:\n:UN:" s.file
   ```

   might write to standard output:

   ```
   User Names for s.file are:
   xyz
   131
   abc
   ```

2. The following example:

   ```
   prs –d "Delta for pgm :M:: :I: – :D: By :P:" –r s.file
   ```

   might write to standard output:

   ```
   Delta for pgm main.c: 3.7 – 77/12/01 By cas
   ```

3. As a special case:

   ```
   prs s.file
   ```

   might write to standard output:

   ```
   s.file:
   <blank line>
   D 1.1 77/12/01 00:00:00 cas 1 000000/00000/00000
   MRs:
   bl78-12345
   bl79-54321
   COMMENTS:
   this is the comment line for s.file initial delta
   <blank line>
   ```

   for each delta table entry of the **D** type. The only option allowed to be used with this special case is the **−a** option.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The phrase ``in which keyword substitution is followed by a <newline>'' is deleted from the end of the second paragraph of Data Keywords (on page 3119).

The interpretation of the *YY* component of the **−c** *cutoff* argument is noted.

Issue 6

The normative text is reworded to emphasize the term ``shall'' for implementation requirements.

The Open Group Base Resolution bwg2001-007 is applied, updating the table in STDOUT with a note that line statistics are capped at 99 999 for the **:Li:**, **:Ld:**, **:Lu:**, and **:DL:** keywords.

The Open Group Interpretation PIN4C.00009 is applied.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ps — report process status

SYNOPSIS

XSI
```
ps [-aA] [-defl] [-g grouplist] [-G grouplist]
    [-n namelist] [-o format]... [-p proclist] [-t termlist]
    [-u userlist] [-U userlist]
```

DESCRIPTION

The *ps* utility shall write information about processes, subject to having appropriate privileges to obtain information about those processes.

By default, *ps* shall select all processes with the same effective user ID as the current user and the same controlling terminal as the invoker.

OPTIONS

The *ps* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−a Write information for all processes associated with terminals. Implementations may omit session leaders from this list.

−A Write information for all processes.

XSI **−d** Write information for all processes, except session leaders.

XSI **−e** Write information for all processes. (Equivalent to **−A**.)

XSI **−f** Generate a **full** listing. (See the STDOUT section for the contents of a **full** listing.)

XSI **−g** *grouplist* Write information for processes whose session leaders are given in *grouplist*. The application shall ensure that the *grouplist* is a single argument in the form of a <blank> or <comma>-separated list.

−G *grouplist* Write information for processes whose real group ID numbers are given in *grouplist*. The application shall ensure that the *grouplist* is a single argument in the form of a <blank> or <comma>-separated list.

XSI **−l** Generate a **long** listing. (See STDOUT for the contents of a **long** listing.)

XSI **−n** *namelist* Specify the name of an alternative system *namelist* file in place of the default. The name of the default file and the format of a *namelist* file are unspecified.

−o *format* Write information according to the format specification given in *format*. This is fully described in the STDOUT section. Multiple **−o** options can be specified; the format specification shall be interpreted as the <space>-separated concatenation of all the *format* option-arguments.

−p *proclist* Write information for processes whose process ID numbers are given in *proclist*. The application shall ensure that the *proclist* is a single argument in the form of a <blank> or <comma>-separated list.

−t *termlist* Write information for processes associated with terminals given in *termlist*. The application shall ensure that the *termlist* is a single argument in the form of a <blank> or <comma>-separated list. Terminal identifiers shall be given in an
XSI implementation-defined format. On XSI-conformant systems, they shall be given in one of two forms: the device's filename (for example, **tty04**) or, if the device's filename starts with **tty**, just the identifier following the characters **tty** (for example, "04").

104526 XSI **–u** *userlist* Write information for processes whose user ID numbers or login names are given
104527 in *userlist*. The application shall ensure that the *userlist* is a single argument in the
104528 form of a <blank> or <comma>-separated list. In the listing, the numerical user ID
104529 shall be written unless the **–f** option is used, in which case the login name shall be
104530 written.

104531 **–U** *userlist* Write information for processes whose real user ID numbers or login names are
104532 given in *userlist*. The application shall ensure that the *userlist* is a single argument
104533 in the form of a <blank> or <comma>-separated list.

104534 XSI With the exception of **–f**, **–l**, **–n** *namelist*, and **–o** *format*, all of the options shown are used to
104535 select processes. If any are specified, the default list shall be ignored and *ps* shall select the
104536 processes represented by the inclusive OR of all the selection-criteria options.

104537 **OPERANDS**

104538 None.

104539 **STDIN**

104540 Not used.

104541 **INPUT FILES**

104542 None.

104543 **ENVIRONMENT VARIABLES**

104544 The following environment variables shall affect the execution of *ps*:

104545 *COLUMNS* Override the system-selected horizontal display line size, used to determine the
104546 number of text columns to display. See XBD Chapter 8 (on page 173) for valid
104547 values and results when it is unset or null.

104548 *LANG* Provide a default value for the internationalization variables that are unset or null.
104549 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
104550 used to determine the values of locale categories.)

104551 *LC_ALL* If set to a non-empty string value, override the values of all the other
104552 internationalization variables.

104553 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
104554 characters (for example, single-byte as opposed to multi-byte characters in
104555 arguments).

104556 *LC_MESSAGES*
104557 Determine the locale that should be used to affect the format and contents of
104558 diagnostic messages written to standard error and informative messages written to
104559 standard output.

104560 *LC_TIME* Determine the format and contents of the date and time strings displayed.

104561 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

104562 *TZ* Determine the timezone used to calculate date and time strings displayed. If *TZ* is
104563 unset or null, an unspecified default timezone shall be used.

104564 **ASYNCHRONOUS EVENTS**

104565 Default.

104566 **STDOUT**

104567 When the **−o** option is not specified, the standard output format is unspecified.

104568 XSI On XSI-conformant systems, the output format shall be as follows. The column headings and
104569 descriptions of the columns in a *ps* listing are given below. The precise meanings of these fields
104570 are implementation-defined. The letters `'f'` and `'l'` (below) indicate the option (**full** or **long**)
104571 that shall cause the corresponding heading to appear; **all** means that the heading always
104572 appears. Note that these two options determine only what information is provided for a process;
104573 they do not determine which processes are listed.

104574	**F**	(l) Flags (octal and additive) associated with the process.
104575	**S**	(l) The state of the process.
104576	**UID**	(f,l) The user ID number of the process owner; the login name is printed
104577		under the **−f** option.
104578	**PID**	(all) The process ID of the process; it is possible to kill a process if this
104579		datum is known.
104580	**PPID**	(f,l) The process ID of the parent process.
104581	**C**	(f,l) Processor utilization for scheduling.
104582	**PRI**	(l) The priority of the process; higher numbers mean lower priority.
104583	**NI**	(l) Nice value; used in priority computation.
104584	**ADDR**	(l) The address of the process.
104585	**SZ**	(l) The size in blocks of the core image of the process.
104586	**WCHAN**	(l) The event for which the process is waiting or sleeping; if blank, the
104587		process is running.
104588	**STIME**	(f) Starting time of the process.
104589	**TTY**	(all) The controlling terminal for the process.
104590	**TIME**	(all) The cumulative execution time for the process.
104591	**CMD**	(all) The command name; the full command name and its arguments are
104592		written under the **−f** option.

104593 A process that has exited and has a parent, but has not yet been waited for by the parent, shall be
104594 marked **defunct**.

104595 Under the option **−f**, *ps* tries to determine the command name and arguments given when the
104596 process was created by examining memory or the swap area. Failing this, the command name, as
104597 it would appear without the option **−f**, is written in square brackets.

104598 The **−o** option allows the output format to be specified under user control.

104599 The application shall ensure that the format specification is a list of names presented as a single
104600 argument, <blank> or <comma>-separated. Each variable has a default header. The default
104601 header can be overridden by appending an <equals-sign> and the new text of the header. The
104602 rest of the characters in the argument shall be used as the header text. The fields specified shall
104603 be written in the order specified on the command line, and should be arranged in columns in the
104604 output. The field widths shall be selected by the system to be at least as wide as the header text
104605 (default or overridden value). If the header text is null, such as **−o** *user=*, the field width shall be
104606 at least as wide as the default header text. If all header text fields are null, no header line shall
104607 be written.

104608 The following names are recognized in the POSIX locale:

104609 **ruser** The real user ID of the process. This shall be the textual user ID, if it can be obtained
104610 and the field width permits, or a decimal representation otherwise.

user The effective user ID of the process. This shall be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

rgroup The real group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

group The effective group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

pid The decimal value of the process ID.

ppid The decimal value of the parent process ID.

pgid The decimal value of the process group ID.

pcpu The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of ``recently'' in this context is unspecified. The CPU time available is determined in an unspecified manner.

vsz The size of the process in (virtual) memory in 1 024 byte units as a decimal integer.

nice The decimal value of the nice value of the process; see *nice*.

etime In the POSIX locale, the elapsed time since the process was started, in the form:

[[*dd***-]***hh***:]***mm***:***ss*

where *dd* shall represent the number of days, *hh* the number of hours, *mm* the number of minutes, and *ss* the number of seconds. The *dd* field shall be a decimal integer. The *hh*, *mm*, and *ss* fields shall be two-digit decimal integers padded on the left with zeros.

time In the POSIX locale, the cumulative CPU time of the process in the form:

[*dd***-]***hh***:***mm***:***ss*

The *dd*, *hh*, *mm*, and *ss* fields shall be as described in the **etime** specifier.

tty The name of the controlling terminal of the process (if any) in the same format used by the *who* utility.

comm The name of the command being executed (*argv*[0] value) as a string.

args The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-defined whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of *ps*.

Any field need not be meaningful in all implementations. In such a case a <hyphen-minus> (**'-'**) should be output in place of the field value.

Only **comm** and **args** shall be allowed to contain <blank> characters; all others shall not. Any implementation-defined variables shall be specified in the system documentation along with the default header and indicating whether the field may contain <blank> characters.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

Table 4-18 Variable Names and Default Headers in *ps*

Format Specifier	Default Header	Format Specifier	Default Header
args	**COMMAND**	**ppid**	**PPID**
comm	**COMMAND**	**rgroup**	**RGROUP**
etime	**ELAPSED**	**ruser**	**RUSER**
group	**GROUP**	**time**	**TIME**
nice	**NI**	**tty**	**TT**
pcpu	**%CPU**	**user**	**USER**
pgid	**PGID**	**vsz**	**VSZ**
pid	**PID**		

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Things can change while *ps* is running; the snapshot it gives is only true for an instant, and might not be accurate by the time it is displayed.

The **args** format specifier is allowed to produce a truncated version of the command arguments. In some implementations, this information is no longer available when the *ps* utility is executed.

If the field width is too narrow to display a textual ID, the system may use a numeric version. Normally, the system would be expected to choose large enough field widths, but if a large number of fields were selected to write, it might squeeze fields to their minimum sizes to fit on one line. One way to ensure adequate width for the textual IDs is to override the default header for a field to make it larger than most or all user or group names.

There is no special quoting mechanism for header text. The header text is the rest of the argument. If multiple header changes are needed, multiple **–o** options can be used, such as:

```
ps –o "user=User Name" –o pid=Process\ ID
```

On some implementations, especially multi-level secure systems, *ps* may be severely restricted and produce information only about child processes owned by the user.

EXAMPLES

The command:

```
ps –o user,pid,ppid=MOM –o args
```

writes at least the following in the POSIX locale:

```
  USER   PID   MOM   COMMAND
```

```
helene    34    12   ps −o uid,pid,ppid=MOM −o args
```

The contents of the **COMMAND** field need not be the same in all implementations, due to possible truncation.

RATIONALE

There is very little commonality between BSD and System V implementations of *ps*. Many options conflict or have subtly different usages. The standard developers attempted to select a set of options for the base standard that were useful on a wide range of systems and selected options that either can be implemented on both BSD and System V-based systems without breaking the current implementations or where the options are sufficiently similar that any changes would not be unduly problematic for users or implementors.

It is recognized that on some implementations, especially multi-level secure systems, *ps* may be nearly useless. The default output has therefore been chosen such that it does not break historical implementations and also is likely to provide at least some useful information on most systems.

The major change is the addition of the format specification capability. The motivation for this invention is to provide a mechanism for users to access a wider range of system information, if the system permits it, in a portable manner. The fields chosen to appear in this volume of POSIX.1-2017 were arrived at after considering what concepts were likely to be both reasonably useful to the ``average'' user and had a reasonable chance of being implemented on a wide range of systems. Again it is recognized that not all systems are able to provide all the information and, conversely, some may wish to provide more. It is hoped that the approach adopted will be sufficiently flexible and extensible to accommodate most systems. Implementations may be expected to introduce new format specifiers.

The default output should consist of a short listing containing the process ID, terminal name, cumulative execution time, and command name of each process.

The preference of the standard developers would have been to make the format specification an operand of the *ps* command. Unfortunately, BSD usage precluded this.

At one time a format was included to display the environment array of the process. This was deleted because there is no portable way to display it.

The **−A** option is equivalent to the BSD **−g** and the SVID **−e**. Because the two systems differed, a mnemonic compromise was selected.

The **−a** option is described with some optional behavior because the SVID omits session leaders, but BSD does not.

In an early proposal, format specifiers appeared for priority and start time. The former was not defined adequately in this volume of POSIX.1-2017 and was removed in deference to the defined nice value; the latter because elapsed time was considered to be more useful.

In a new BSD version of *ps*, a **−O** option can be used to write all of the default information, followed by additional format specifiers. This was not adopted because the default output is implementation-defined. Nevertheless, this is a useful option that should be reserved for that purpose. In the **−o** option for the POSIX Shell and Utilities *ps*, the format is the concatenation of each **−o**. Therefore, the user can have an alias or function that defines the beginning of their desired format and add more fields to the end of the output in certain cases where that would be useful.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use the same format.

The **pcpu** field indicates that the CPU time available is determined in an unspecified manner. This is because it is difficult to express an algorithm that is useful across all possible machine architectures. Historical counterparts to this value have attempted to show percentage of use in the recent past, such as the preceding minute. Frequently, these values for all processes did not add up to 100%. Implementations are encouraged to provide data in this field to users that will help them identify processes currently affecting the performance of the system.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-148 is applied, updating the OPTIONS section.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0160 [584] is applied.

NAME

pwd — return working directory name

SYNOPSIS

```
pwd [-L|-P]
```

DESCRIPTION

The *pwd* utility shall write to standard output an absolute pathname of the current working directory, which does not contain the filenames dot or dot-dot.

OPTIONS

The *pwd* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

−L If the *PWD* environment variable contains an absolute pathname of the current directory and the pathname does not contain any components that are dot or dot-dot, *pwd* shall write this pathname to standard output, except that if the *PWD* environment variable is longer than {PATH_MAX} bytes including the terminating null, it is unspecified whether *pwd* writes this pathname to standard output or behaves as if the **−P** option had been specified. Otherwise, the **−L** option shall behave as the **−P** option.

−P The pathname written to standard output shall not contain any components that refer to files of type symbolic link. If there are multiple pathnames that the *pwd* utility could write to standard output, one beginning with a single <slash> character and one or more beginning with two <slash> characters, then it shall write the pathname beginning with a single <slash> character. The pathname shall not contain any unnecessary <slash> characters after the leading one or two <slash> characters.

If both **−L** and **−P** are specified, the last one shall apply. If neither **−L** nor **−P** is specified, the *pwd* utility shall behave as if **−L** had been specified.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pwd*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

104801 *PWD* An absolute pathname of the current working directory. If an application sets or
104802 unsets the value of *PWD*, the behavior of *pwd* is unspecified.

104803 **ASYNCHRONOUS EVENTS**
104804 Default.

104805 **STDOUT**
104806 The *pwd* utility output is an absolute pathname of the current working directory:

104807 `"%s\n", <directory pathname>`

104808 **STDERR**
104809 The standard error shall be used only for diagnostic messages.

104810 **OUTPUT FILES**
104811 None.

104812 **EXTENDED DESCRIPTION**
104813 None.

104814 **EXIT STATUS**
104815 The following exit values shall be returned:

104816 0 Successful completion.

104817 >0 An error occurred.

104818 **CONSEQUENCES OF ERRORS**
104819 If an error is detected, output shall not be written to standard output, a diagnostic message shall
104820 be written to standard error, and the exit status is not zero.

104821 **APPLICATION USAGE**
104822 If the pathname obtained from *pwd* is longer than {PATH_MAX} bytes, it could produce an error
104823 if passed to *cd*. Therefore, in order to return to that directory it may be necessary to break the
104824 pathname into sections shorter than {PATH_MAX} and call *cd* on each section in turn (the first
104825 section being an absolute pathname and subsequent sections being relative pathnames).

104826 **EXAMPLES**
104827 None.

104828 **RATIONALE**
104829 Some implementations have historically provided *pwd* as a shell special built-in command.

104830 In most utilities, if an error occurs, partial output may be written to standard output. This does
104831 not happen in historical implementations of *pwd*. Because *pwd* is frequently used in historical
104832 shell scripts without checking the exit status, it is important that the historical behavior is
104833 required here; therefore, the CONSEQUENCES OF ERRORS section specifically disallows any
104834 partial output being written to standard output.

104835 An earlier version of this standard stated that the *PWD* environment variable was affected when
104836 the **−P** option was in effect. This was incorrect; conforming implementations do not do this.

104837 **FUTURE DIRECTIONS**
104838 None.

104839 **SEE ALSO**
104840 *cd*

104841 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The −**P** and −**L** options are added to describe actions relating to symbolic links as specified in the IEEE P1003.2b draft standard.

Issue 7

Austin Group Interpretation 1003.1-2001 #097 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Changes to the *pwd* utility and *PWD* environment variable have been made to match the changes to the *getcwd*( ) function made for Austin Group Interpretation 1003.1-2001 #140.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0161 [471] is applied.

NAME

qalter ‡'alter batch job

SYNOPSIS

OB BE
```
qalter [-a date_time] [-A account_string] [-c interval] [-e path_name]
    [-h hold_list] [-j join_list] [-k keep_list] [-l resource_list]
    [-m mail_options] [-M mail_list] [-N name] [-o path_name]
    [-p priority] [-r y|n] [-S path_name_list] [-u user_list]
    job_identifier...
```

DESCRIPTION

The attributes of a batch job are altered by a request to the batch server that manages the batch job. The *qalter* utility is a user-accessible batch client that requests the alteration of the attributes of one or more batch jobs.

The *qalter* utility shall alter the attributes of those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qalter* utility shall alter the attributes of batch jobs in the order in which the batch *job_identifier*s are presented to the utility.

If the *qalter* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

For each batch *job_identifier* for which the *qalter* utility succeeds, each attribute of the identified batch job shall be altered as indicated by all the options presented to the utility.

For each identified batch job for which the *qalter* utility fails, the utility shall not alter any attribute of the batch job.

For each batch job that the *qalter* utility processes, the utility shall not modify any attribute other than those required by the options and option-arguments presented to the utility.

The *qalter* utility shall alter batch jobs by sending a *Modify Job Request* to the batch server that manages each batch job. At the time the *qalter* utility exits, it shall have modified the batch job corresponding to each successfully processed batch *job_identifier*. An attempt to alter the attributes of a batch job in the RUNNING state is implementation-defined.

OPTIONS

The *qalter* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

-a *date_time* Redefine the time at which the batch job becomes eligible for execution.

The *date_time* argument shall be in the same form and represent the same time as for the *touch* utility. The time so represented shall be set into the *Execution_Time* attribute of the batch job. If the time specified is earlier than the current time, the **-a** option shall have no effect.

-A *account_string*
Redefine the account to which the resource consumption of the batch job should be charged.

The syntax of the *account_string* option-argument is unspecified.

The *qalter* utility shall set the *Account_Name* attribute of the batch job to the value of the *account_string* option-argument.

104896 **−c** *interval* Redefine whether the batch job should be checkpointed, and if so, how often.

104897 The *qalter* utility shall accept a value for the interval option-argument that is one of
104898 the following:

104899 `n` No checkpointing is to be performed on the batch job
104900 (NO_CHECKPOINT).

104901 `s` Checkpointing is to be performed only when the batch server is shut
104902 down (CHECKPOINT_AT_SHUTDOWN).

104903 `c` Automatic periodic checkpointing is to be performed at the
104904 *Minimum_Cpu_Interval* attribute of the batch queue, in units of CPU
104905 minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).

104906 `c=`*minutes* Automatic periodic checkpointing is to be performed every *minutes*
104907 of CPU time, or every *Minimum_Cpu_Interval* minutes, whichever is
104908 greater. The *minutes* argument shall conform to the syntax for
104909 unsigned integers and shall be greater than zero.

104910 An implementation may define other checkpoint intervals. The conformance
104911 document for an implementation shall describe any alternative checkpoint
104912 intervals, how they are specified, their internal behavior, and how they affect the
104913 behavior of the utility.

104914 The *qalter* utility shall set the *Checkpoint* attribute of the batch job to the value of the
104915 *interval* option-argument.

104916 **−e** *path_name*
104917 Redefine the path to be used for the standard error stream of the batch job.

104918 The *qalter* utility shall accept a *path_name* option-argument that conforms to the
104919 syntax of the *path_name* element defined in the System Interfaces volume of
104920 POSIX.1-2017, which can be preceded by a host name element of the form
104921 *hostname*:.

104922 If the *path_name* option-argument constitutes an absolute pathname, the *qalter*
104923 utility shall set the *Error_Path* attribute of the batch job to the value of the
104924 *path_name* option-argument, including the host name element, if present.

104925 If the *path_name* option-argument constitutes a relative pathname and no host
104926 name element is specified, the *qalter* utility shall set the *Error_Path* attribute of the
104927 batch job to the value of the absolute pathname derived by expanding the
104928 *path_name* option-argument relative to the current directory of the process that
104929 executes the *qalter* utility.

104930 If the *path_name* option-argument constitutes a relative pathname and a host name
104931 element is specified, the *qalter* utility shall set the *Error_Path* attribute of the batch
104932 job to the value of the option-argument without expansion.

104933 If the *path_name* option-argument does not include a host name element, the *qalter*
104934 utility shall prefix the pathname in the *Error_Path* attribute with *hostname*:, where
104935 *hostname* is the name of the host upon which the *qalter* utility is being executed.

104936 **−h** *hold_list* Redefine the types of holds, if any, on the batch job. The *qalter* **−h** option shall
104937 accept a value for the *hold_list* option-argument that is a string of alphanumeric
104938 characters in the portable character set.

104939 The *qalter* utility shall accept a value for the *hold_list* option-argument that is a

104940 string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character
104941 `'n'`. For each unique character in the *hold_list* option-argument, the *qalter* utility
104942 shall add a value to the *Hold_Types* attribute of the batch job as follows, each
104943 representing a different hold type:

104944 `u` USER

104945 `s` SYSTEM

104946 `o` OPERATOR

104947 If any of these characters are duplicated in the *hold_list* option-argument, the
104948 duplicates shall be ignored. An existing *Hold_Types* attribute can be cleared by the
104949 hold type:

104950 `n` NO_HOLD

104951 The *qalter* utility shall consider it an error if any hold type other than `'n'` is
104952 combined with hold type `'n'`. Strictly conforming applications shall not repeat
104953 any of the characters `'u'`, `'s'`, `'o'`, or `'n'` within the *hold_list* option-argument.
104954 The *qalter* utility shall permit the repetition of characters, but shall not assign
104955 additional meaning to the repeated characters. An implementation may define
104956 other hold types. The conformance document for an implementation shall describe
104957 any additional hold types, how they are specified, their internal behavior, and how
104958 they affect the behavior of the utility.

104959 **−j** *join_list* Redefine which streams of the batch job are to be merged. The *qalter* **−j** option shall
104960 accept a value for the *join_list* option-argument that is a string of alphanumeric
104961 characters in the portable character set.

104962 The *qalter* utility shall accept a *join_list* option-argument that consists of one or
104963 more of the characters `'e'` and `'o'`, or the single character `'n'`.

104964 All of the other batch job output streams specified shall be merged into the output
104965 stream represented by the character listed first in the *join_list* option-argument.

104966 For each unique character in the *join_list* option-argument, the *qalter* utility shall
104967 add a value to the *Join_Path* attribute of the batch job as follows, each representing
104968 a different batch job stream to join:

104969 `e` The standard error of the batch job (JOIN_STD_ERROR).

104970 `o` The standard output of the batch job (JOIN_STD_OUTPUT).

104971 An existing *Join_Path* attribute can be cleared by the join type:

104972 `n` NO_JOIN

104973 If `'n'` is specified, then no files are joined. The *qalter* utility shall consider it an
104974 error if any join type other than `'n'` is combined with join type `'n'`.

104975 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
104976 `'n'` within the *join_list* option-argument. The *qalter* utility shall permit the
104977 repetition of characters, but shall not assign additional meaning to the repeated
104978 characters.

104979 An implementation may define other join types. The conformance document for an
104980 implementation shall describe any additional batch job streams, how they are
104981 specified, their internal behavior, and how they affect the behavior of the utility.

104982 **–k** *keep_list* Redefine which output of the batch job to retain on the execution host.

104983 The *qalter* **–k** option shall accept a value for the *keep_list* option-argument that is a
104984 string of alphanumeric characters in the portable character set.

104985 The *qalter* utility shall accept a *keep_list* option-argument that consists of one or
104986 more of the characters `'e'` and `'o'`, or the single character `'n'`.

104987 For each unique character in the *keep_list* option-argument, the *qalter* utility shall
104988 add a value to the *Keep_Files* attribute of the batch job as follows, each representing
104989 a different batch job stream to keep:

104990 `e` The standard error of the batch job (KEEP_STD_ERROR).

104991 `o` The standard output of the batch job (KEEP_STD_OUTPUT).

104992 If both `'e'` and `'o'` are specified, then both files are retained. An existing
104993 *Keep_Files* attribute can be cleared by the keep type:

104994 `n` NO_KEEP

104995 If `'n'` is specified, then no files are retained. The *qalter* utility shall consider it an
104996 error if any keep type other than `'n'` is combined with keep type `'n'`.

104997 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
104998 `'n'` within the *keep_list* option-argument. The *qalter* utility shall permit the
104999 repetition of characters, but shall not assign additional meaning to the repeated
105000 characters. An implementation may define other keep types. The conformance
105001 document for an implementation shall describe any additional keep types, how
105002 they are specified, their internal behavior, and how they affect the behavior of the
105003 utility.

105004 **–l** *resource_list*

105005 Redefine the resources that are allowed or required by the batch job.

105006 The *qalter* utility shall accept a *resource_list* option-argument that conforms to the
105007 following syntax:

105008 `resource=value[,,resource=value,,...]`

105009 The *qalter* utility shall set one entry in the value of the *Resource_List* attribute of the
105010 batch job for each resource listed in the *resource_list* option-argument.

105011 Because the list of supported resource names might vary by batch server, the *qalter*
105012 utility shall rely on the batch server to validate the resource names and associated
105013 values. See Section 3.3.3 (on page 2451) for a means of removing *keyword=value*
105014 (and *value@keyword*) pairs and other general rules for list-oriented batch job
105015 attributes.

105016 **–m** *mail_options*

105017 Redefine the points in the execution of the batch job at which the batch server is to
105018 send mail about a change in the state of the batch job.

105019 The *qalter* **–m** option shall accept a value for the *mail_options* option-argument that
105020 is a string of alphanumeric characters in the portable character set.

105021 The *qalter* utility shall accept a value for the *mail_options* option-argument that is a
105022 string of one or more of the characters `'e'`, `'b'`, and `'a'`, or the single character
105023 `'n'`. For each unique character in the *mail_options* option-argument, the *qalter*
105024 utility shall add a value to the *Mail_Users* attribute of the batch job as follows, each

105025 representing a different time during the life of a batch job at which to send mail:

105026 `e` MAIL_AT_EXIT

105027 `b` MAIL_AT_BEGINNING

105028 `a` MAIL_AT_ABORT

105029 If any of these characters are duplicated in the *mail_options* option-argument, the
105030 duplicates shall be ignored.

105031 An existing *Mail_Points* attribute can be cleared by the mail type:

105032 `n` NO_MAIL

105033 If `'n'` is specified, then mail is not sent. The *qalter* utility shall consider it an error
105034 if any mail type other than `'n'` is combined with mail type `'n'`. Strictly
105035 conforming applications shall not repeat any of the characters `'e'`, `'b'`, `'a'`, or
105036 `'n'` within the *mail_options* option-argument. The *qalter* utility shall permit the
105037 repetition of characters but shall not assign additional meaning to the repeated
105038 characters.

105039 An implementation may define other mail types. The conformance document for
105040 an implementation shall describe any additional mail types, how they are
105041 specified, their internal behavior, and how they affect the behavior of the utility.

105042 **−M** *mail_list* Redefine the list of users to which the batch server that executes the batch job is to
105043 send mail, if the batch server sends mail about the batch job.

105044 The syntax of the *mail_list* option-argument is unspecified. If the implementation
105045 of the *qalter* utility uses a name service to locate users, the utility shall accept the
105046 syntax used by the name service.

105047 If the implementation of the *qalter* utility does not use a name service to locate
105048 users, the implementation shall accept the following syntax for user names:

105049 `mail_address[,,mail_address,,...]`

105050 The interpretation of *mail_address* is implementation-defined.

105051 The *qalter* utility shall set the *Mail_Users* attribute of the batch job to the value of
105052 the *mail_list* option-argument.

105053 **−N** *name* Redefine the name of the batch job.

105054 The *qalter* **−N** option shall accept a value for the *name* option-argument that is a
105055 string of up to 15 alphanumeric characters in the portable character set where the
105056 first character is alphabetic.

105057 The syntax of the *name* option-argument is unspecified.

105058 The *qalter* utility shall set the *Job_Name* attribute of the batch job to the value of the
105059 *name* option-argument.

105060 **−o** *path_name*
105061 Redefine the path for the standard output of the batch job.

105062 The *qalter* utility shall accept a *path_name* option-argument that conforms to the
105063 syntax of the *path_name* element defined in the System Interfaces volume of
105064 POSIX.1-2017, which can be preceded by a host name element of the form
105065 *hostname*:.

105066 If the *path_name* option-argument constitutes an absolute pathname, the *qalter*
105067 utility shall set the *Output_Path* attribute of the batch job to the value of the
105068 *path_name* option-argument.

105069 If the *path_name* option-argument constitutes a relative pathname and no host
105070 name element is specified, the *qalter* utility shall set the *Output_Path* attribute of the
105071 batch job to the absolute pathname derived by expanding the *path_name* option-
105072 argument relative to the current directory of the process that executes the *qalter*
105073 utility.

105074 If the *path_name* option-argument constitutes a relative pathname and a host name
105075 element is specified, the *qalter* utility shall set the *Output_Path* attribute of the batch
105076 job to the value of the *path_name* option-argument without any expansion of the
105077 pathname.

105078 If the *path_name* option-argument does not include a host name element, the *qalter*
105079 utility shall prefix the pathname in the *Output_Path* attribute with *hostname*:, where
105080 *hostname* is the name of the host upon which the *qalter* utility is being executed.

105081 **–p** *priority* Redefine the priority of the batch job.

105082 The *qalter* utility shall accept a value for the priority option-argument that
105083 conforms to the syntax for signed decimal integers, and which is not less than
105084 –1 024 and not greater than 1 023.

105085 The *qalter* utility shall set the *Priority* attribute of the batch job to the value of the
105086 *priority* option-argument.

105087 **–r** `y|n` Redefine whether the batch job is rerunnable.

105088 If the value of the option-argument is `'y'`, the *qalter* utility shall set the *Rerunable*
105089 attribute of the batch job to TRUE.

105090 If the value of the option-argument is `'n'`, the *qalter* utility shall set the *Rerunable*
105091 attribute of the batch job to FALSE.

105092 The *qalter* utility shall consider it an error if any character other than `'y'` or `'n'` is
105093 specified in the option-argument.

105094 **–S** *path_name_list*
105095 Redefine the shell that interprets the script at the destination system.

105096 The *qalter* utility shall accept a *path_name_list* option-argument that conforms to the
105097 following syntax:

105098 `pathname[@host][,pathname[@host],...]`

105099 The *qalter* utility shall accept only one pathname that is missing a corresponding
105100 host name. The *qalter* utility shall allow only one pathname per named host.

105101 The *qalter* utility shall add a value to the *Shell_Path_List* attribute of the batch job
105102 for each entry in the *path_name_list* option-argument. See Section 3.3.3 (on page
105103 2451) for a means of removing *keyword=value* (and *value@keyword*) pairs and other
105104 general rules for list-oriented batch job attributes.

105105 **–u** *user_list* Redefine the user name under which the batch job is to run at the destination
105106 system.

105107 The *qalter* utility shall accept a *user_list* option-argument that conforms to the
105108 following syntax:

105109 `username[@host][,,username[@host],,...]`

105110 The *qalter* utility shall accept only one user name that is missing a corresponding
105111 host name. The *qalter* utility shall accept only one user name per named host.

105112 The *qalter* utility shall add a value to the *User_List* attribute of the batch job for each
105113 entry in the *user_list* option-argument. See Section 3.3.3 (on page 2451) for a means
105114 of removing *keyword=value* (and *value@keyword*) pairs and other general rules for
105115 list-oriented batch job attributes.

105116 **OPERANDS**

105117 The *qalter* utility shall accept one or more operands that conform to the syntax for a batch
105118 *job_identifier* (see Section 3.3.1, on page 2449).

105119 **STDIN**

105120 Not used.

105121 **INPUT FILES**

105122 None.

105123 **ENVIRONMENT VARIABLES**

105124 The following environment variables shall affect the execution of *qalter*:

105125 *LANG* Provide a default value for the internationalization variables that are unset or null.
105126 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
105127 used to determine the values of locale categories.)

105128 *LC_ALL* If set to a non-empty string value, override the values of all the other
105129 internationalization variables.

105130 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
105131 characters (for example, single-byte as opposed to multi-byte characters in
105132 arguments).

105133 *LC_MESSAGES*
105134 Determine the locale that should be used to affect the format and contents of
105135 diagnostic messages written to standard error.

105136 *LOGNAME* Determine the login name of the user.

105137 *TZ* Determine the timezone used to interpret the *date-time* option-argument. If *TZ* is
105138 unset or null, an unspecified default timezone shall be used.

105139 **ASYNCHRONOUS EVENTS**

105140 Default.

105141 **STDOUT**

105142 None.

105143 **STDERR**

105144 The standard error shall be used only for diagnostic messages.

105145 **OUTPUT FILES**

105146 None.

105147 **EXTENDED DESCRIPTION**

105148 None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qalter* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qalter* utility attempts to locate the batch job on other batch servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qalter* utility allows users to change the attributes of a batch job.

As a means of altering a queued job, the *qalter* utility is superior to deleting and requeuing the batch job insofar as an altered job retains its place in the queue with some traditional selection algorithms. In addition, the *qalter* utility is both shorter and simpler than a sequence of *qdel* and *qsub* utilities.

The result of an attempt on the part of a user to alter a batch job in a RUNNING state is implementation-defined because a batch job in the RUNNING state will already have opened its output files and otherwise performed any actions indicated by the options in effect at the time the batch job began execution.

The options processed by the *qalter* utility are identical to those of the *qsub* utility, with a few exceptions: **−V**, **−v**, and **−q**. The **−V** and **−v** are inappropriate for the *qalter* utility, since they capture potentially transient environment information from the submitting process. The **−q** option would specify a new queue, which would largely negate the previously stated advantage of using *qalter*; furthermore, the *qmove* utility provides a superior means of moving jobs.

Each of the following paragraphs provides the rationale for a *qalter* option.

Additional rationale concerning these options can be found in the rationale for the *qsub* utility.

The **−a** option allows users to alter the date and time at which a batch job becomes eligible to run.

The **−A** option allows users to change the account that will be charged for the resources consumed by the batch job. Support for the **−A** option is mandatory for conforming implementations of *qalter*, even though support of accounting is optional for servers. Whether or not to support accounting is left to the implementor of the server, but mandatory support of the **−A** option assures users of a consistent interface and allows them to control accounting on servers that support accounting.

The **−c** option allows users to alter the checkpointing interval of a batch job. A checkpointing system, which is not defined by POSIX.1-2017, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of POSIX.1-2017 provides the checkpointing interval option. Support for checkpointing is optional for servers.

105194 The **–e** option allows users to alter the name and location of the standard error stream written by
105195 a batch job. However, the path of the standard error stream is meaningless if the value of the
105196 *Join_Path* attribute of the batch job is TRUE.

105197 The **–h** option allows users to set the hold type in the *Hold_Types* attribute of a batch job. The
105198 *qhold* and *qrls* utilities add or remove hold types to the *Hold_Types* attribute, respectively. The **–h**
105199 option has been modified to allow for implementation-defined hold types.

105200 The **–j** option allows users to alter the decision to join (merge) the standard error stream of the
105201 batch job with the standard output stream of the batch job.

105202 The **–l** option allows users to change the resource limits imposed on a batch job.

105203 The **–m** option allows users to modify the list of points in the life of a batch job at which the
105204 designated users will receive mail notification.

105205 The **–M** option allows users to alter the list of users who will receive notification about events in
105206 the life of a batch job.

105207 The **–N** option allows users to change the name of a batch job.

105208 The **–o** option allows users to alter the name and path to which the standard output stream of
105209 the batch job will be written.

105210 The **–P** option allows users to modify the priority of a batch job. Support for priority is optional
105211 for batch servers.

105212 The **–r** option allows users to alter the rerunability status of a batch job.

105213 The **–S** option allows users to change the name and location of the shell image that will be
105214 invoked to interpret the script of the batch job. This option has been modified to allow a list of
105215 shell name and locations associated with different hosts.

105216 The **–u** option allows users to change the user identifier under which the batch job will execute.

105217 The *job_identifier* operand syntax is provided so that the user can differentiate between the
105218 originating and destination (or executing) batch server. These may or may not be the same. The
105219 *.server_name* portion identifies the originating batch server, while the *@server* portion identifies
105220 the destination batch server.

105221 Historically, the *qalter* utility has been a component of the Network Queuing System (NQS), the
105222 existing practice from which this utility has been derived.

105223 **FUTURE DIRECTIONS**

105224 The *qalter* utility may be removed in a future version.

105230 **Issue 6**

105231 The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

105232 IEEE PASC Interpretation 1003.2 #182 is applied, clarifying the description of the **–a** option.

105233 **Issue 7**

105234 The *qalter* utility is marked obsolescent.

105235 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

105236 **NAME**

105237 qdel ‡’delete batch jobs

105238 **SYNOPSIS**

105239 OB BE
```
qdel job_identifier...
```

105240 **DESCRIPTION**

105241 A batch job is deleted by sending a request to the batch server that manages the batch job. A
105242 batch job that has been deleted is no longer subject to management by batch services.

105243 The *qdel* utility is a user-accessible client of batch services that requests the deletion of one or
105244 more batch jobs.

105245 The *qdel* utility shall request a batch server to delete those batch jobs for which a batch
105246 *job_identifier* is presented to the utility.

105247 The *qdel* utility shall delete batch jobs in the order in which their batch *job_identifier*s are
105248 presented to the utility.

105249 If the *qdel* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to
105250 process the remaining batch *job_identifier*s, if any.

105251 The *qdel* utility shall delete each batch job by sending a *Delete Job Request* to the batch server that
105252 manages the batch job.

105253 The *qdel* utility shall not exit until the batch job corresponding to each successfully processed
105254 batch *job_identifier* has been deleted.

105255 **OPTIONS**

105256 None.

105257 **OPERANDS**

105258 The *qdel* utility shall accept one or more operands that conform to the syntax for a batch
105259 *job_identifier* (see Section 3.3.1, on page 2449).

105260 **STDIN**

105261 Not used.

105262 **INPUT FILES**

105263 None.

105264 **ENVIRONMENT VARIABLES**

105265 The following environment variables shall affect the execution of *qdel*:

105266 *LANG* Provide a default value for the internationalization variables that are unset or null.
105267 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
105268 used to determine the values of locale categories.)

105269 *LC_ALL* If set to a non-empty string value, override the values of all the other
105270 internationalization variables.

105271 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
105272 characters (for example, single-byte as opposed to multi-byte characters in
105273 arguments).

105274 *LC_MESSAGES*
105275 Determine the locale that should be used to affect the format and contents of
105276 diagnostic messages written to standard error.

105277 *LOGNAME* Determine the login name of the user.

105278 **ASYNCHRONOUS EVENTS**
105279 Default.

105280 **STDOUT**
105281 An implementation of the *qdel* utility may write informative messages to standard output.

105282 **STDERR**
105283 The standard error shall be used only for diagnostic messages.

105284 **OUTPUT FILES**
105285 None.

105286 **EXTENDED DESCRIPTION**
105287 None.

105288 **EXIT STATUS**
105289 The following exit values shall be returned:

105290 0 Successful completion.

105291 >0 An error occurred.

105292 **CONSEQUENCES OF ERRORS**
105293 In addition to the default behavior, the *qdel* utility shall not be required to write a diagnostic
105294 message to standard error when the error reply received from a batch server indicates that the
105295 batch *job_identifier* does not exist on the server. Whether or not the *qdel* utility waits to output the
105296 diagnostic message while attempting to locate the job on other servers is implementation-
105297 defined.

105298 **APPLICATION USAGE**
105299 None.

105300 **EXAMPLES**
105301 None.

105302 **RATIONALE**
105303 The *qdel* utility allows users and administrators to delete jobs.

105304 The *qdel* utility provides functionality that is not otherwise available. For example, the *kill* utility
105305 of the operating system does not suffice. First, to use the *kill* utility, the user might have to log in
105306 on a remote node, because the *kill* utility does not operate across the network. Second, unlike
105307 *qdel*, *kill* cannot remove jobs from queues. Lastly, the arguments of the *qdel* utility are job
105308 identifiers rather than process identifiers, and so this utility can be passed the output of the
105309 *qselect* utility, thus providing users with a means of deleting a list of jobs.

105310 Because a set of jobs can be selected using the *qselect* utility, the *qdel* utility has not been
105311 complicated with options that provide for selection of jobs. Instead, the batch jobs to be deleted
105312 are identified individually by their job identifiers.

105313 Historically, the *qdel* utility has been a component of NQS, the existing practice on which it is
105314 based. However, the *qdel* utility defined in this volume of POSIX.1-2017 does not provide an
105315 option for specifying a signal number to send to the batch job prior to the killing of the process;
105316 that capability has been subsumed by the *qsig* utility.

105317 A discussion was held about the delays of networking and the possibility that the batch server
105318 may never respond, due to a down router, down batch server, or other network mishap. The
105319 DESCRIPTION records this under the words ``fails to process any job identifier''. In the broad
105320 sense, the network problem is also an error, which causes the failure to process the batch job

105321 identifier.

105322 **FUTURE DIRECTIONS**

105323 The *qdel* utility may be removed in a future version.

105324 **SEE ALSO**

105325 Chapter 3 (on page 2427), *kill*, *qselect*, *qsig*

105327 **CHANGE HISTORY**

105328 Derived from IEEE Std 1003.2d-1994.

105329 **Issue 6**

105330 The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

105331 **Issue 7**

105332 The *qdel* utility is marked obsolescent.

105333 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qhold ‡'hold batch jobs

SYNOPSIS

OB BE
```
qhold [–h hold_list] job_identifier...
```

DESCRIPTION

A hold is placed on a batch job by a request to the batch server that manages the batch job. A batch job that has one or more holds is not eligible for execution. The *qhold* utility is a user-accessible client of batch services that requests one or more types of hold to be placed on one or more batch jobs.

The *qhold* utility shall place holds on those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qhold* utility shall place holds on batch jobs in the order in which their batch *job_identifier*s are presented to the utility. If the *qhold* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qhold* utility shall place holds on each batch job by sending a *Hold Job Request* to the batch server that manages the batch job.

The *qhold* utility shall not exit until holds have been placed on the batch job corresponding to each successfully processed batch *job_identifier*.

OPTIONS

The *qhold* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported by the implementation:

–h *hold_list* Define the types of holds to be placed on the batch job.

The *qhold* **–h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see XBD Section 6.1, on page 125).

The *qhold* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

For each unique character in the *hold_list* option-argument, the *qhold* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

`u` USER

`s` SYSTEM

`o` OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

An existing *Hold_Types* attribute can be cleared by the following hold type:

`n` NO_HOLD

The *qhold* utility shall consider it an error if any hold type other than `'n'` is combined with hold type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`,

105375 '○', or 'n' within the *hold_list* option-argument. The *qhold* utility shall permit the
105376 repetition of characters, but shall not assign additional meaning to the repeated
105377 characters.

105378 An implementation may define other hold types. The conformance document for
105379 an implementation shall describe any additional hold types, how they are
105380 specified, their internal behavior, and how they affect the behavior of the utility.

105381 If the **–h** option is not presented to the *qhold* utility, the implementation shall set
105382 the *Hold_Types* attribute to USER.

105383 **OPERANDS**

105384 The *qhold* utility shall accept one or more operands that conform to the syntax for a batch
105385 *job_identifier* (see Section 3.3.1, on page 2449).

105386 **STDIN**

105387 Not used.

105388 **INPUT FILES**

105389 None.

105390 **ENVIRONMENT VARIABLES**

105391 The following environment variables shall affect the execution of *qhold*:

105392 *LANG* Provide a default value for the internationalization variables that are unset or null.
105393 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
105394 used to determine the values of locale categories.)

105395 *LC_ALL* If set to a non-empty string value, override the values of all the other
105396 internationalization variables.

105397 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
105398 characters (for example, single-byte as opposed to multi-byte characters in
105399 arguments).

105400 *LC_MESSAGES*
105401 Determine the locale that should be used to affect the format and contents of
105402 diagnostic messages written to standard error.

105403 *LOGNAME* Determine the login name of the user.

105404 **ASYNCHRONOUS EVENTS**

105405 Default.

105406 **STDOUT**

105407 None.

105408 **STDERR**

105409 The standard error shall be used only for diagnostic messages.

105410 **OUTPUT FILES**

105411 None.

105412 **EXTENDED DESCRIPTION**

105413 None.

105414 **EXIT STATUS**

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qhold* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qhold* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qhold* utility allows users to place a hold on one or more jobs. A hold makes a batch job ineligible for execution.

The *qhold* utility has options that allow the user to specify the type of hold. Should the user wish to place a hold on a set of jobs that meet a selection criteria, such a list of jobs can be acquired using the *qselect* utility.

The **−h** option allows the user to specify the type of hold that is to be placed on the job. This option allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The USER and OPERATOR holds are distinct. The batch server that manages the batch job will verify that the user is authorized to set the specified hold for the batch job.

Mail is not required on hold because the administrator has the tools and libraries to build this option if he or she wishes.

Historically, the *qhold* utility has been a part of some existing batch systems, although it has not traditionally been a part of the NQS.

FUTURE DIRECTIONS

The *qhold* utility may be removed in a future version.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qmove ‡’move batch jobs

SYNOPSIS

OB BE

```
qmove destination job_identifier...
```

DESCRIPTION

To move a batch job is to remove the batch job from the batch queue in which it resides and instantiate the batch job in another batch queue. A batch job is moved by a request to the batch server that manages the batch job. The *qmove* utility is a user-accessible batch client that requests the movement of one or more batch jobs.

The *qmove* utility shall move those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qmove* utility shall move batch jobs in the order in which the corresponding batch *job_identifier*s are presented to the utility.

If the *qmove* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qmove* utility shall move batch jobs by sending a *Move Job Request* to the batch server that manages each batch job. The *qmove* utility shall not exit before the batch jobs corresponding to all successfully processed batch *job_identifier*s have been moved.

OPTIONS

None.

OPERANDS

The *qmove* utility shall accept one operand that conforms to the syntax for a destination (see Section 3.3.2, on page 2450).

The *qmove* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1, on page 2449).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qmove*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qmove* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qmove* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qmove* utility allows users to move jobs between queues.

The alternative to using the *qmove* utility—deleting the batch job and requeuing it—entails considerably more typing.

Since the means of selecting jobs based on attributes has been encapsulated in the *qselect* utility, the only option of the *qmove* utility concerns authorization. The **−u** option provides the user with the convenience of changing the user identifier under which the batch job will execute. Minimalism and consistency have taken precedence over convenience; the **−u** option has been deleted because the equivalent capability exists with the **−u** option of the *qalter* utility.

FUTURE DIRECTIONS

The *qmove* utility may be removed in a future version.

Chapter 3 (on page 2427), *qalter*, *qselect*

XBD Chapter 8 (on page 173)

105535 **CHANGE HISTORY**

105536 Derived from IEEE Std 1003.2d-1994.

105537 **Issue 6**

105538 The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

105539 **Issue 7**

105540 The *qmove* utility is marked obsolescent.

105541 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

105542 **NAME**

105543 qmsg ‡'send message to batch jobs

105544 **SYNOPSIS**

105545 OB BE
```
qmsg [-EO] message_string job_identifier...
```

105546 **DESCRIPTION**

105547 To send a message to a batch job is to request that a server write a message string into one or
105548 more output files of the batch job. A message is sent to a batch job by a request to the batch
105549 server that manages the batch job. The *qmsg* utility is a user-accessible batch client that requests
105550 the sending of messages to one or more batch jobs.

105551 The *qmsg* utility shall write messages into the files of batch jobs by sending a *Job Message Request*
105552 to the batch server that manages the batch job. The *qmsg* utility shall not directly write the
105553 message into the files of the batch job.

105554 The *qmsg* utility shall send a *Job Message Request* for those batch jobs, and only those batch jobs,
105555 for which a batch *job_identifier* is presented to the utility.

105556 The *qmsg* utility shall send *Job Message Request*s for batch jobs in the order in which their batch
105557 *job_identifier*s are presented to the utility.

105558 If the *qmsg* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to
105559 process the remaining batch *job_identifier*s, if any.

105560 The *qmsg* utility shall not exit before a *Job Message Request* has been sent to the server that
105561 manages the batch job that corresponds to each successfully processed batch *job_identifier*.

105562 **OPTIONS**

105563 The *qmsg* utility shall conform to XBD Section 12.2 (on page 216).

105564 The following options shall be supported by the implementation:

105565 **−E** Specify that the message is written to the standard error of each batch job.

105566 The *qmsg* utility shall write the message into the standard error of the batch job.

105567 **−O** Specify that the message is written to the standard output of each batch job.

105568 The *qmsg* utility shall write the message into the standard output of the batch job.

105569 If neither the **−O** nor the **−E** option is presented to the *qmsg* utility, the utility shall write the
105570 message into an implementation-defined file. The conformance document for the
105571 implementation shall describe the name and location of the implementation-defined file. If both
105572 the **−O** and the **−E** options are presented to the *qmsg* utility, then the utility shall write the
105573 messages to both standard output and standard error.

105574 **OPERANDS**

105575 The *qmsg* utility shall accept a minimum of two operands, *message_string* and one or more batch
105576 *job_identifier*s.

105577 The *message_string* operand shall be the string to be written to one or more output files of the
105578 batch job followed by a <newline>. If the string contains <blank> characters, then the
105579 application shall ensure that the string is quoted. The *message_string* shall be encoded in the
105580 portable character set (see XBD Section 6.1, on page 125).

105581 All remaining operands are batch *job_identifier*s that conform to the syntax for a batch
105582 *job_identifier* (see Section 3.3.1, on page 2449).

105583 **STDIN**

105584 Not used.

105585 **INPUT FILES**

105586 None.

105587 **ENVIRONMENT VARIABLES**

105588 The following environment variables shall affect the execution of *qmsg*:

105589 *LANG* Provide a default value for the internationalization variables that are unset or null.
105590 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
105591 used to determine the values of locale categories.)

105592 *LC_ALL* If set to a non-empty string value, override the values of all the other
105593 internationalization variables.

105594 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
105595 characters (for example, single-byte as opposed to multi-byte characters in
105596 arguments).

105597 *LC_MESSAGES*

105598 Determine the locale that should be used to affect the format and contents of
105599 diagnostic messages written to standard error.

105600 *LOGNAME* Determine the login name of the user.

105601 **ASYNCHRONOUS EVENTS**

105602 Default.

105603 **STDOUT**

105604 None.

105605 **STDERR**

105606 The standard error shall be used only for diagnostic messages.

105607 **OUTPUT FILES**

105608 None.

105609 **EXTENDED DESCRIPTION**

105610 None.

105611 **EXIT STATUS**

105612 The following exit values shall be returned:

105613 0 Successful completion.

105614 >0 An error occurred.

105615 **CONSEQUENCES OF ERRORS**

105616 In addition to the default behavior, the *qmsg* utility shall not be required to write a diagnostic
105617 message to standard error when the error reply received from a batch server indicates that the
105618 batch *job_identifier* does not exist on the server. Whether or not the *qmsg* utility waits to output
105619 the diagnostic message while attempting to locate the job on other servers is implementation-
105620 defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qmsg* utility allows users to write messages into the output files of running jobs. Users, including operators and administrators, have a number of occasions when they want to place messages in the output files of a batch job. For example, if a disk that is being used by a batch job is showing errors, the operator might note this in the standard error stream of the batch job.

The options of the *qmsg* utility provide users with the means of placing the message in the output stream of their choice. The default output stream for the message—if the user does not designate an output stream ‡is implementation-defined, since many implementations will provide, as an extension to this volume of POSIX.1-2017, a log file that shows the history of utility execution.

If users wish to send a message to a set of jobs that meet a selection criteria, the *qselect* utility can be used to acquire the appropriate list of job identifiers.

The **−E** option allows users to place the message in the standard error stream of the batch job.

The **−O** option allows users to place the message in the standard output stream of the batch job.

Historically, the *qmsg* utility is an existing practice in the offerings of one or more implementors of an NQS-derived batch system. The utility has been found to be useful enough that it deserves to be included in this volume of POSIX.1-2017.

FUTURE DIRECTIONS

The *qmsg* utility may be removed in a future version.

NAME

qrerun — rerun batch jobs

SYNOPSIS

OB BE

```
qrerun job_identifier...
```

DESCRIPTION

To rerun a batch job is to terminate the session leader of the batch job, delete any associated checkpoint files, and return the batch job to the batch queued state. A batch job is rerun by a request to the batch server that manages the batch job. The *qrerun* utility is a user-accessible batch client that requests the rerunning of one or more batch jobs.

The *qrerun* utility shall rerun those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qrerun* utility shall rerun batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qrerun* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qrerun* utility shall rerun batch jobs by sending a *Rerun Job Request* to the batch server that manages each batch job.

For each successfully processed batch *job_identifier*, the *qrerun* utility shall have rerun the corresponding batch job at the time the utility exits.

OPTIONS

None.

OPERANDS

The *qrerun* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1, on page 2449).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qrerun*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qrerun* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qrerun* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qrerun* utility allows users to cause jobs in the running state to exit and rerun.

The *qrerun* utility is a new utility, *vis-a-vis* existing practice, that has been defined in this volume of POSIX.1-2017 to correct user-perceived deficiencies in the existing practice.

FUTURE DIRECTIONS

The *qrerun* utility may be removed in a future version.

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

105733 **Issue 7**

105734 The *qrerun* utility is marked obsolescent.

105735 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qrls — release batch jobs

SYNOPSIS

OB BE

```
qrls [–h hold_list] job_identifier...
```

DESCRIPTION

A batch job might have one or more holds, which prevent the batch job from executing. A batch job from which all the holds have been removed becomes eligible for execution and is said to have been released. A batch job hold is removed by sending a request to the batch server that manages the batch job. The *qrls* utility is a user-accessible client of batch services that requests holds be removed from one or more batch jobs.

The *qrls* utility shall remove one or more holds from those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qrls* utility shall remove holds from batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qrls* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qrls* utility shall remove holds on each batch job by sending a *Release Job Request* to the batch server that manages the batch job.

The *qrls* utility shall not exit until the holds have been removed from the batch job corresponding to each successfully processed batch *job_identifier*.

OPTIONS

The *qrls* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported by the implementation:

–h *hold_list* Define the types of holds to be removed from the batch job.

The *qrls* **–h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see XBD Section 6.1, on page 125).

The *qrls* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

For each unique character in the *hold_list* option-argument, the *qrls* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

`u` USER

`s` SYSTEM

`o` OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

An existing *Hold_Types* attribute can be cleared by the following hold type:

`n` NO_HOLD

The *qrls* utility shall consider it an error if any hold type other than `'n'` is combined with hold type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`, `'o'`, or `'n'` within the *hold_list* option-argument. The *qrls* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the –**h** option is not presented to the *qrls* utility, the implementation shall remove the USER hold in the *Hold_Types* attribute.

OPERANDS

The *qrls* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1, on page 2449).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qrls*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

105817 **EXIT STATUS**

105818 The following exit values shall be returned:

105819 0 Successful completion.

105820 >0 An error occurred.

105821 **CONSEQUENCES OF ERRORS**

105822 In addition to the default behavior, the *qrls* utility shall not be required to write a diagnostic
105823 message to standard error when the error reply received from a batch server indicates that the
105824 batch *job_identifier* does not exist on the server. Whether or not the *qrls* utility waits to output the
105825 diagnostic message while attempting to locate the job on other servers is implementation-
105826 defined.

105827 **APPLICATION USAGE**

105828 None.

105829 **EXAMPLES**

105830 None.

105831 **RATIONALE**

105832 The *qrls* utility allows users, operators, and administrators to remove holds from jobs.

105833 The *qrls* utility does not support any job selection options or wildcard arguments. Users may
105834 acquire a list of jobs selected by attributes using the *qselect* utility. For example, a user could
105835 select all of their held jobs.

105836 The **–h** option allows the user to specify the type of hold that is to be removed. This option
105837 allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The batch
105838 server that manages the batch job will verify whether the user is authorized to remove the
105839 specified hold for the batch job. If more than one type of hold has been placed on the batch job, a
105840 user may wish to remove only some of them.

105841 Mail is not required on release because the administrator has the tools and libraries to build this
105842 option if required.

105843 The *qrls* utility is a new utility *vis-a-vis* existing practice; it has been defined in this volume of
105844 POSIX.1-2017 as the natural complement to the *qhold* utility.

105845 **FUTURE DIRECTIONS**

105846 The *qrls* utility may be removed in a future version.

105850 **CHANGE HISTORY**

105851 Derived from IEEE Std 1003.2d-1994.

105852 **Issue 6**

105853 The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

105854 **Issue 7**

105855 The *qrls* utility is marked obsolescent.

105856 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qselect ‡'select batch jobs

SYNOPSIS

OB BE
```
qselect [−a [op]date_time] [−A account_string] [−c [op]interval]
    [−h hold_list] [−l resource_list] [−N name] [−p [op]priority]
    [−q destination] [−r y|n] [−s states] [−u user_list]
```

DESCRIPTION

To select a set of batch jobs is to return the batch *job_identifier*s for each batch job that meets a list of selection criteria. A set of batch jobs is selected by a request to a batch server. The *qselect* utility is a user-accessible batch client that requests the selection of batch jobs.

Upon successful completion, the *qselect* utility shall have returned a list of zero or more batch *job_identifier*s that meet the criteria specified by the options and option-arguments presented to the utility.

The *qselect* utility shall select batch jobs by sending a *Select Jobs Request* to a batch server. The *qselect* utility shall not exit until the server replies to each request generated.

For each option presented to the *qselect* utility, the utility shall restrict the set of selected batch jobs as described in the OPTIONS section.

The *qselect* utility shall not restrict selection of batch jobs except by authorization and as required by the options presented to the utility.

When an option is specified with a mandatory or optional *op* component to the option-argument, then *op* shall specify a relation between the value of a certain batch job attribute and the *value* component of the option-argument. If an *op* is allowable on an option, then the description of the option letter indicates the *op* as either mandatory or optional. Acceptable strings for the *op* component, and the relation the string indicates, are shown in the following list:

`.eq.` The value represented by the attribute of the batch job is equal to the value represented by the option-argument.

`.ge.` The value represented by the attribute of the batch job is greater than or equal to the value represented by the option-argument.

`.gt.` The value represented by the attribute of the batch job is greater than the value represented by the option-argument.

`.lt.` The value represented by the attribute of the batch job is less than the value represented by the option-argument.

`.le.` The value represented by the attribute of the batch job is less than or equal to the value represented by the option-argument.

`.ne.` The value represented by the attribute of the batch job is not equal to the value represented by the option-argument.

OPTIONS

The *qselect* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

−a [*op***]***date_time*

Restrict selection to a specific time, or a range of times.

The *qselect* utility shall select only batch jobs for which the value of the

105900 *Execution_Time* attribute is related to the Epoch equivalent of the local time
105901 expressed by the value of the *date_time* component of the option-argument in the
105902 manner indicated by the value of the *op* component of the option-argument.

105903 The *qselect* utility shall accept a *date_time* component of the option-argument that
105904 conforms to the syntax of the *time* operand of the *touch* utility.

105905 If the *op* component of the option-argument is not presented to the *qselect* utility,
105906 the utility shall select batch jobs for which the *Execution_Time* attribute is equal to
105907 the *date_time* component of the option-argument.

105908 When comparing times, the *qselect* utility shall use the following definitions for the
105909 *op* component of the option-argument:

105910 `.eq.` The time represented by value of the *Execution_Time* attribute of the batch
105911 job is equal to the time represented by the *date_time* component of the
105912 option-argument.

105913 `.ge.` The time represented by value of the *Execution_Time* attribute of the batch
105914 job is after or equal to the time represented by the *date_time* component of
105915 the option-argument.

105916 `.gt.` The time represented by value of the *Execution_Time* attribute of the batch
105917 job is after the time represented by the *date_time* component of the option-
105918 argument.

105919 `.lt.` The time represented by value of the *Execution_Time* attribute of the batch
105920 job is before the time represented by the *date_time* component of the
105921 option-argument.

105922 `.le.` The time represented by value of the *Execution_Time* attribute of the batch
105923 job is before or equal to the time represented by the *date_time* component
105924 of the option-argument.

105925 `.ne.` The time represented by value of the *Execution_Time* attribute of the batch
105926 job is not equal to the time represented by the *date_time* component of the
105927 option-argument.

105928 The *qselect* utility shall accept the defined character strings for the *op* component of
105929 the option-argument.

105930 **−A** *account_string*

105931 Restrict selection to the batch jobs charging a specified account.

105932 The *qselect* utility shall select only batch jobs for which the value of the
105933 *Account_Name* attribute of the batch job matches the value of the *account_string*
105934 option-argument.

105935 The syntax of the *account_string* option-argument is unspecified.

105936 **−c [***op***]***interval*

105937 Restrict selection to batch jobs within a range of checkpoint intervals.

105938 The *qselect* utility shall select only batch jobs for which the value of the *Checkpoint*
105939 attribute relates to the value of the *interval* component of the option-argument in
105940 the manner indicated by the value of the *op* component of the option-argument.

105941 If the *op* component of the option-argument is omitted, the *qselect* utility shall select
105942 batch jobs for which the value of the *Checkpoint* attribute is equal to the value of the
105943 *interval* component of the option-argument.

105944 When comparing checkpoint intervals, the *qselect* utility shall use the following
105945 definitions for the *op* component of the option-argument:

105946 `.eq.` The value of the *Checkpoint* attribute of the batch job equals the value of
105947 the *interval* component of the option-argument.

105948 `.ge.` The value of the *Checkpoint* attribute of the batch job is greater than or
105949 equal to the value of the *interval* component option-argument.

105950 `.gt.` The value of the *Checkpoint* attribute of the batch job is greater than the
105951 value of the *interval* component option-argument.

105952 `.lt.` The value of the *Checkpoint* attribute of the batch job is less than the value
105953 of the *interval* component option-argument.

105954 `.le.` The value of the *Checkpoint* attribute of the batch job is less than or equal
105955 to the value of the *interval* component option-argument.

105956 `.ne.` The value of the *Checkpoint* attribute of the batch job does not equal the
105957 value of the *interval* component option-argument.

105958 The *qselect* utility shall accept the defined character strings for the *op* component of
105959 the option-argument.

105960 The ordering relationship for the values of the interval option-argument is defined
105961 to be:

105962 `` `n' .gt. `s' .gt. `c=`*minutes*`' .ge. `c' ``

105963 When comparing *Checkpoint* attributes with an interval having the value of the
105964 single character `'u'`, only equality or inequality are valid comparisons.

105965 **–h** *hold_list* Restrict selection to batch jobs that have a specific type of hold.

105966 The *qselect* utility shall select only batch jobs for which the value of the *Hold_Types*
105967 attribute matches the value of the *hold_list* option-argument.

105968 The *qselect* **–h** option shall accept a value for the *hold_list* option-argument that is a
105969 string of alphanumeric characters in the portable character set (see XBD Section
105970 6.1, on page 125).

105971 The *qselect* utility shall accept a value for the *hold_list* option-argument that is a
105972 string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character
105973 `'n'`.

105974 Each unique character in the *hold_list* option-argument of the *qselect* utility is
105975 defined as follows, each representing a different hold type:

105976 `u` USER

105977 `s` SYSTEM

105978 `o` OPERATOR

105979 If any of these characters are duplicated in the *hold_list* option-argument, the
105980 duplicates shall be ignored.

105981 The *qselect* utility shall consider it an error if any hold type other than `'n'` is
105982 combined with hold type `'n'`.

105983 Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`,
105984 `'o'`, or `'n'` within the *hold_list* option-argument. The *qselect* utility shall permit

105985 the repetition of characters, but shall not assign additional meaning to the repeated
105986 characters.

105987 An implementation may define other hold types. The conformance document for
105988 an implementation shall describe any additional hold types, how they are
105989 specified, their internal behavior, and how they affect the behavior of the utility.

105990 **–l** *resource_list*
105991 Restrict selection to batch jobs with specified resource limits and attributes.

105992 The *qselect* utility shall accept a *resource_list* option-argument with the following
105993 syntax:

105994 *resource_name op value* **[,,***resource_name op value***,, ...]**

105995 When comparing resource values, the *qselect* utility shall use the following
105996 definitions for the *op* component of the option-argument:

105997 `.eq.` The value of the resource of the same name in the *Resource_List* attribute
105998 of the batch job equals the value of the value component of the option-
105999 argument.

106000 `.ge.` The value of the resource of the same name in the *Resource_List* attribute
106001 of the batch job is greater than or equal to the value of the *value*
106002 component of the option-argument.

106003 `.gt.` The value of the resource of the same name in the *Resource_List* attribute
106004 of the batch job is greater than the value of the value component of the
106005 option-argument.

106006 `.lt.` The value of the resource of the same name in the *Resource_List* attribute
106007 of the batch job is less than the value of the value component of the
106008 option-argument.

106009 `.ne.` The value of the resource of the same name in the *Resource_List* attribute
106010 of the batch job does not equal the value of the value component of the
106011 option-argument.

106012 `.le.` The value of the resource of the same name in the *Resource_List* attribute
106013 of the batch job is less than or equal to the value of the *value* component of
106014 the option-argument.

106015 When comparing the limit of a *Resource_List* attribute with the *value* component of
106016 the option-argument, if the limit, the value, or both are non-numeric, only equality
106017 or inequality are valid comparisons.

106018 The *qselect* utility shall select only batch jobs for which the values of the
106019 *resource_name*s listed in the *resource_list* option-argument match the corresponding
106020 limits of the *Resource_List* attribute of the batch job.

106021 Limits of *resource_name*s present in the *Resource_List* attribute of the batch job that
106022 have no corresponding values in the *resource_list* option-argument shall not be
106023 considered when selecting batch jobs.

106024 **–N** *name* Restrict selection to batch jobs with a specified name.

106025 The *qselect* utility shall select only batch jobs for which the value of the *Job_Name*
106026 attribute matches the value of the *name* option-argument. The string specified in
106027 the *name* option-argument shall be passed, uninterpreted, to the server. This allows
106028 an implementation to match ``wildcard'' patterns against batch job names.

106029 An implementation shall describe in the conformance document the format it
106030 supports for matching against the *Job_Name* attribute.

106031 −**p** [*op*]*priority*
106032 Restrict selection to batch jobs of the specified priority or range of priorities.

106033 The *qselect* utility shall select only batch jobs for which the value of the *Priority*
106034 attribute of the batch job relates to the value of the *priority* component of the
106035 option-argument in the manner indicated by the value of the *op* component of the
106036 option-argument.

106037 If the *op* component of the option-argument is omitted, the *qselect* utility shall select
106038 batch jobs for which the value of the *Priority* attribute of the batch job is equal to
106039 the value of the *priority* component of the option-argument.

106040 When comparing priority values, the *qselect* utility shall use the following
106041 definitions for the *op* component of the option-argument:

106042 `.eq.` The value of the *Priority* attribute of the batch job equals the value of the
106043 *priority* component of the option-argument.

106044 `.ge.` The value of the *Priority* attribute of the batch job is greater than or equal
106045 to the value of the *priority* component option-argument.

106046 `.gt.` The value of the *Priority* attribute of the batch job is greater than the value
106047 of the *priority* component option-argument.

106048 `.lt.` The value of the *Priority* attribute of the batch job is less than the value of
106049 the *priority* component option-argument.

106050 `.lt.` The value of the *Priority* attribute of the batch job is less than or equal to
106051 the value of the *priority* component option-argument.

106052 `.ne.` The value of the *Priority* attribute of the batch job does not equal the value
106053 of the *priority* component option-argument.

106054 −**q** *destination*
106055 Restrict selection to the specified batch queue or server, or both.

106056 The *qselect* utility shall select only batch jobs that are located at the destination
106057 indicated by the value of the *destination* option-argument.

106058 The destination defines a batch queue, a server, or a batch queue at a server.

106059 The *qselect* utility shall accept an option-argument for the −**q** option that conforms
106060 to the syntax for a destination. If the −**q** option is not presented to the *qselect* utility,
106061 the utility shall select batch jobs from all batch queues at the default batch server.

106062 If the option-argument describes only a batch queue, the *qselect* utility shall select
106063 only batch jobs from the batch queue of the specified name at the default batch
106064 server. The means by which *qselect* determines the default server is
106065 implementation-defined.

106066 If the option-argument describes only a batch server, the *qselect* utility shall select
106067 batch jobs from all the batch queues at that batch server.

106068 If the option-argument describes both a batch queue and a batch server, the *qselect*
106069 utility shall select only batch jobs from the specified batch queue at the specified
106070 server.

106071 −**r** `y|n` Restrict selection to batch jobs with the specified rerunability status.

106072 The *qselect* utility shall select only batch jobs for which the value of the *Rerunable*
106073 attribute of the batch job matches the value of the option-argument.

106074 The *qselect* utility shall accept a value for the option-argument that consists of
106075 either the single character `'y'` or the single character `'n'`. The character `'y'`
106076 represents the value TRUE, and the character `'n'` represents the value FALSE.

106077 −**s** *states* Restrict selection to batch jobs in the specified states.

106078 The *qselect* utility shall accept an option-argument that consists of any combination
106079 of the characters `'e'`, `'q'`, `'r'`, `'w'`, `'h'`, and `'t'`.

106080 Conforming applications shall not repeat any character in the option-argument.
106081 The *qselect* utility shall permit the repetition of characters in the option-argument,
106082 but shall not assign additional meaning to repeated characters.

106083 The *qselect* utility shall interpret the characters in the *states* option-argument as
106084 follows:

106085 `e` Represents the EXITING state.

106086 `q` Represents the QUEUED state.

106087 `r` Represents the RUNNING state.

106088 `t` Represents the TRANSITING state.

106089 `h` Represents the HELD state.

106090 `w` Represents the WAITING state.

106091 For each character in the *states* option-argument, the *qselect* utility shall select batch
106092 jobs in the corresponding state.

106093 −**u** *user_list* Restrict selection to batch jobs owned by the specified user names.

106094 The *qselect* utility shall select only the batch jobs of those users specified in the
106095 *user_list* option-argument.

106096 The *qselect* utility shall accept a *user_list* option-argument that conforms to the
106097 following syntax:

106098 *username*`[@`*host*`][,,`*username*`[@`*host*`],, ...]`

106099 The *qselect* utility shall accept only one user name that is missing a corresponding
106100 host name. The *qselect* utility shall accept only one user name per named host.

106101 **OPERANDS**

106102 None.

106103 **STDIN**

106104 Not used.

106105 **INPUT FILES**

106106 None.

106107 **ENVIRONMENT VARIABLES**

106108 The following environment variables shall affect the execution of *qselect*:

106109 *LANG* Provide a default value for the internationalization variables that are unset or null.
106110 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
106111 used to determine the values of locale categories.)

106112 *LC_ALL* If set to a non-empty string value, override the values of all the other
106113 internationalization variables.

106114 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
106115 characters (for example, single-byte as opposed to multi-byte characters in
106116 arguments).

106117 *LC_MESSAGES*
106118 Determine the locale that should be used to affect the format and contents of
106119 diagnostic messages written to standard error.

106120 *LOGNAME* Determine the login name of the user.

106121 *TZ* Determine the timezone used to interpret the *date-time* option-argument. If *TZ* is
106122 unset or null, an unspecified default timezone shall be used.

106123 **ASYNCHRONOUS EVENTS**
106124 Default.

106125 **STDOUT**
106126 The *qselect* utility shall write zero or more batch *job_identifier*s to standard output.

106127 The *qselect* utility shall separate the batch *job_identifier*s written to standard output by white
106128 space.

106129 The *qselect* utility shall write batch *job_identifier*s in the following format:

106130 `sequence_number.server_name@server`

106131 **STDERR**
106132 The standard error shall be used only for diagnostic messages.

106133 **OUTPUT FILES**
106134 None.

106135 **EXTENDED DESCRIPTION**
106136 None.

106137 **EXIT STATUS**
106138 The following exit values shall be returned:

106139 0 Successful completion.

106140 >0 An error occurred.

106141 **CONSEQUENCES OF ERRORS**
106142 Default.

APPLICATION USAGE

None.

EXAMPLES

The following example shows how a user might use the *qselect* utility in conjunction with the *qdel* utility to delete all of his or her jobs in the queued state without affecting any jobs that are already running:

```
qdel $(qselect −s q)
```

or:

```
qselect −s q || xargs qdel
```

RATIONALE

The *qselect* utility allows users to acquire a list of job identifiers that match user-specified selection criteria. The list of identifiers returned by the *qselect* utility conforms to the syntax of the batch job identifier list processed by a utility such as *qmove*, *qdel*, and *qrls*. The *qselect* utility is thus a powerful tool for causing another batch system utility to act upon a set of jobs that match a list of selection criteria.

The options of the *qselect* utility let the user apply a number of useful filters for selecting jobs. Each option further restricts the selection of jobs. Many of the selection options allow the specification of a relational operator. The FORTRAN-like syntax of the operator—that is, `".lt."` ‡was chosen rather than the C-like" `<=` " meta-characters.

The **−a** option allows users to restrict the selected jobs to those that have been submitted (or altered) to wait until a particular time. The time period is determined by the argument of this option, which includes both a time and an operator ‡ít is thus possible to select jobs waiting until a specific time, jobs waiting until after a certain time, or those waiting for a time before the specified time.

The **−A** option allows users to restrict the selected jobs to those that have been submitted (or altered) to charge a particular account.

The **−c** option allows users to restrict the selected jobs to those whose checkpointing interval falls within the specified range.

The **−l** option allows users to select those jobs whose resource limits fall within the range indicated by the value of the option. For example, a user could select those jobs for which the CPU time limit is greater than two hours.

The **−N** option allows users to select jobs by job name. For instance, all the parts of a task that have been divided in parallel jobs might be given the same name, and thus manipulated as a group by means of this option.

The **−q** option allows users to select jobs in a specified queue.

The **−r** option allows users to select only those jobs with a specified rerun criteria. For instance, a user might select only those jobs that can be rerun for use with the *qrerun* utility.

The **−s** option allows users to select only those jobs that are in a certain state.

The **−u** option allows users to select jobs that have been submitted to execute under a particular account.

The selection criteria provided by the options of the *qselect* utility allow users to select jobs based on all the appropriate attributes that can be assigned to jobs by the *qsub* utility.

Historically, the *qselect* utility has not been a part of existing practice; it is an improvement that

has been introduced in this volume of POSIX.1-2017.

FUTURE DIRECTIONS

The *qselect* utility may be removed in a future version.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qsig ‡'signal batch jobs

SYNOPSIS

OB BE

```
qsig [−s signal] job_identifier...
```

DESCRIPTION

To signal a batch job is to send a signal to the session leader of the batch job. A batch job is signaled by sending a request to the batch server that manages the batch job. The *qsig* utility is a user-accessible batch client that requests the signaling of a batch job.

The *qsig* utility shall signal those batch jobs for which a batch *job_identifier* is presented to the utility. The *qsig* utility shall not signal any batch jobs whose batch *job_identifier*s are not presented to the utility.

The *qsig* utility shall signal batch jobs in the order in which the corresponding batch *job_identifier*s are presented to the utility. If the *qsig* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qsig* utility shall signal batch jobs by sending a *Signal Job Request* to the batch server that manages the batch job.

For each successfully processed batch *job_identifier*, the *qsig* utility shall have received a completion reply to each *Signal Job Request* sent to a batch server at the time the utility exits.

OPTIONS

The *qsig* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported by the implementation:

−s *signal* Define the signal to be sent to the batch job.

The *qsig* utility shall accept a *signal* option-argument that is either a symbolic signal name or an unsigned integer signal number (see the POSIX.1-1990 standard, Section 3.3.1.1). The *qsig* utility shall accept signal names for which the SIG prefix has been omitted.

If the *signal* option-argument is a signal name, the *qsig* utility shall send that name.

If the *signal* option-argument is a number, the *qsig* utility shall send the signal value represented by the number.

If the **−s** option is not presented to the *qsig* utility, the utility shall send the signal SIGTERM to each signaled batch job.

OPERANDS

The *qsig* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1, on page 2449).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qsig*:

106237 *LANG* Provide a default value for the internationalization variables that are unset or null.
106238 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
106239 used to determine the values of locale categories.)

106240 *LC_ALL* If set to a non-empty string value, override the values of all the other
106241 internationalization variables.

106242 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
106243 characters (for example, single-byte as opposed to multi-byte characters in
106244 arguments).

106245 *LC_MESSAGES*
106246 Determine the locale that should be used to affect the format and contents of
106247 diagnostic messages written to standard error.

106248 *LOGNAME* Determine the login name of the user.

106249 **ASYNCHRONOUS EVENTS**
106250 Default.

106251 **STDOUT**
106252 An implementation of the *qsig* utility may write informative messages to standard output.

106253 **STDERR**
106254 The standard error shall be used only for diagnostic messages.

106255 **OUTPUT FILES**
106256 None.

106257 **EXTENDED DESCRIPTION**
106258 None.

106259 **EXIT STATUS**
106260 The following exit values shall be returned:

106261 0 Successful completion.

106262 >0 An error occurred.

106263 **CONSEQUENCES OF ERRORS**
106264 In addition to the default behavior, the *qsig* utility shall not be required to write a diagnostic
106265 message to standard error when the error reply received from a batch server indicates that the
106266 batch *job_identifier* does not exist on the server. Whether or not the *qsig* utility waits to output the
106267 diagnostic message while attempting to locate the batch job on other servers is implementation-
106268 defined.

106269 **APPLICATION USAGE**
106270 None.

106271 **EXAMPLES**
106272 None.

106273 **RATIONALE**
106274 The *qsig* utility allows users to signal batch jobs.

106275 A user may be unable to signal a batch job with the *kill* utility of the operating system for a
106276 number of reasons. First, the process ID of the batch job may be unknown to the user. Second,
106277 the processes of the batch job may be on a remote node. However, by virtue of communication
106278 between batch nodes, the *qsig* utility can arrange for the signaling of a process.

106279 Because a batch job that is not running cannot be signaled, and because the signal may not

terminate the batch job, the *qsig* utility is not a substitute for the *qdel* utility.

The options of the *qsig* utility allow the user to specify the signal that is to be sent to the batch job.

The **−s** option allows users to specify a signal by name or by number, and thus override the default signal. The POSIX.1-1990 standard defines signals by both name and number.

The *qsig* utility is a new utility, *vis-a-vis* existing practice; it has been defined in this volume of POSIX.1-2017 in response to user-perceived shortcomings in existing practice.

FUTURE DIRECTIONS

The *qsig* utility may be removed in a future version.

Issue 7

The *qsig* utility is marked obsolescent.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qstat ‡'show status of batch jobs

SYNOPSIS

OB BE
```
qstat [−f] job_identifier...
qstat −Q [−f] destination...
qstat −B [−f] server_name...
```

DESCRIPTION

The status of a batch job, batch queue, or batch server is obtained by a request to the server. The *qstat* utility is a user-accessible batch client that requests the status of one or more batch jobs, batch queues, or servers, and writes the status information to standard output.

For each successfully processed batch *job_identifier*, the *qstat* utility shall display information about the corresponding batch job.

For each successfully processed destination, the *qstat* utility shall display information about the corresponding batch queue.

For each successfully processed server name, the *qstat* utility shall display information about the corresponding server.

The *qstat* utility shall acquire batch job status information by sending a *Job Status Request* to a batch server. The *qstat* utility shall acquire batch queue status information by sending a *Queue Status Request* to a batch server. The *qstat* utility shall acquire server status information by sending a *Server Status Request* to a batch server.

OPTIONS

The *qstat* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

−f Specify that a full display is produced.

The minimum contents of a full display are specified in the STDOUT section.

Additional contents and format of a full display are implementation-defined.

−Q Specify that the operand is a destination.

The *qstat* utility shall display information about each batch queue at each destination identified as an operand.

−B Specify that the operand is a server name.

The *qstat* utility shall display information about each server identified as an operand.

OPERANDS

If the **−Q** option is presented to the *qstat* utility, the utility shall accept one or more operands that conform to the syntax for a destination (see Section 3.3.2, on page 2450).

If the **−B** option is presented to the *qstat* utility, the utility shall accept one or more *server_name* operands.

If neither the **−B** nor the **−Q** option is presented to the *qstat* utility, the utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1, on page 2449).

106339 **STDIN**

106340 Not used.

106341 **INPUT FILES**

106342 None.

106343 **ENVIRONMENT VARIABLES**

106344 The following environment variables shall affect the execution of *qstat*:

106345 *HOME* Determine the pathname of the user's home directory.

106346 *LANG* Provide a default value for the internationalization variables that are unset or null.
106347 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
106348 used to determine the values of locale categories.)

106349 *LC_ALL* If set to a non-empty string value, override the values of all the other
106350 internationalization variables.

106351 *LC_COLLATE*
106352 Determine the locale for the behavior of ranges, equivalence classes, and multi-
106353 character collating elements within regular expressions.

106354 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
106355 characters (for example, single-byte as opposed to multi-byte characters in
106356 arguments).

106357 *LC_MESSAGES*
106358 Determine the locale that should be used to affect the format and contents of
106359 diagnostic messages written to standard error.

106360 *LC_NUMERIC*
106361 Determine the locale for selecting the radix character used when writing floating-
106362 point formatted output.

106363 **ASYNCHRONOUS EVENTS**

106364 Default.

106365 **STDOUT**

106366 If an operand presented to the *qstat* utility is a batch *job_identifier* and the **−f** option is not
106367 specified, the *qstat* utility shall display the following items on a single line, in the stated order,
106368 with white space between each item, for each successfully processed operand:

106369 The batch *job_identifier*

106370 The batch job name

106371 The *Job_Owner* attribute

106372 The CPU time used by the batch job

106373 The batch job state

106374 The batch job location

106375 If an operand presented to the *qstat* utility is a batch *job_identifier* and the **−f** option is specified,
106376 the *qstat* utility shall display the following items for each success fully processed operand:

106377 The batch *job_identifier*

106378 The batch job name

106379 The *Job_Owner* attribute

106380 The execution user ID

106381 The CPU time used by the batch job

106382 The batch job state

106383 The batch job location

106384 Additional implementation-defined information, if any, about the batch job or batch queue

106385 If an operand presented to the *qstat* utility is a destination, the −**Q** option is specified, and the −**f**
106386 option is not specified, the *qstat* utility shall display the following items on a single line, in the
106387 stated order, with white space between each item, for each successfully processed operand:

106388 The batch queue name

106389 The maximum number of batch jobs that shall be run in the batch queue concurrently

106390 The total number of batch jobs in the batch queue

106391 The status of the batch queue

106392 For each state, the number of batch jobs in that state in the batch queue and the name of
106393 the state

106394 The type of batch queue (execution or routing)

106395 If the operands presented to the *qstat* utility are destinations, the −**Q** option is specified, and the
106396 −**f** option is specified, the *qstat* utility shall display the following items for each successfully
106397 processed operand:

106398 The batch queue name

106399 The maximum number of batch jobs that shall be run in the batch queue concurrently

106400 The total number of batch jobs in the batch queue

106401 The status of the batch queue

106402 For each state, the number of batch jobs in that state in the batch queue and the name of
106403 the state

106404 The type of batch queue (execution or routing)

106405 Additional implementation-defined information, if any, about the batch queue

106406 If the operands presented to the *qstat* utility are batch server names, the −**B** option is specified,
106407 and the −**f** option is not specified, the *qstat* utility shall display the following items on a single
106408 line, in the stated order, with white space between each item, for each successfully processed
106409 operand:

106410 The batch server name

106411 The maximum number of batch jobs that shall be run in the batch queue concurrently

106412 The total number of batch jobs managed by the batch server

106413 The status of the batch server

106414 For each state, the number of batch jobs in that state and the name of the state

106415 If the operands presented to the *qstat* utility are server names, the −**B** option is specified, and the
106416 −**f** option is specified, the *qstat* utility shall display the following items for each successfully

106417 processed operand:

106418 The server name

106419 The maximum number of batch jobs that shall be run in the batch queue concurrently

106420 The total number of batch jobs managed by the server

106421 The status of the server

106422 For each state, the number of batch jobs in that state and the name of the state

106423 Additional implementation-defined information, if any, about the server

106424 **STDERR**

106425 The standard error shall be used only for diagnostic messages.

106426 **OUTPUT FILES**

106427 None.

106428 **EXTENDED DESCRIPTION**

106429 None.

106430 **EXIT STATUS**

106431 The following exit values shall be returned:

106432 0 Successful completion.

106433 >0 An error occurred.

106434 **CONSEQUENCES OF ERRORS**

106435 In addition to the default behavior, the *qstat* utility shall not be required to write a diagnostic
106436 message to standard error when the error reply received from a batch server indicates that the
106437 batch *job_identifier* does not exist on the server. Whether or not the *qstat* utility waits to output
106438 the diagnostic message while attempting to locate the batch job on other servers is
106439 implementation-defined.

106440 **APPLICATION USAGE**

106441 None.

106442 **EXAMPLES**

106443 None.

106444 **RATIONALE**

106445 The *qstat* utility allows users to display the status of jobs and list the batch jobs in queues.

106446 The operands of the *qstat* utility may be either job identifiers, queues (specified as destination
106447 identifiers), or batch server names. The **−Q** and **−B** options, or absence thereof, indicate the
106448 nature of the operands.

106449 The other options of the *qstat* utility allow the user to control the amount of information
106450 displayed and the format in which it is displayed. Should a user wish to display the status of a
106451 set of jobs that match a selection criteria, the *qselect* utility may be used to acquire such a list.

106452 The **−f** option allows users to request a ``full'' display in an implementation-defined format.

106453 Historically, the *qstat* utility has been a part of the NQS and its derivatives, the existing practice
106454 on which it is based.

FUTURE DIRECTIONS

The *qstat* utility may be removed in a future version.

The *qstat* utility is marked obsolescent.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

qsub ‡'submit a script

SYNOPSIS

OB BE
```
qsub [−a date_time] [−A account_string] [−c interval]
    [−C directive_prefix] [−e path_name] [−h] [−j join_list]
    [−k keep_list] [−m mail_options] [−M mail_list] [−N name]
    [−o path_name] [−p priority] [−q destination] [−r y|n]
    [−S path_name_list] [−u user_list] [−v variable_list] [−V]
    [−z] [script]
```

DESCRIPTION

To submit a script is to create a batch job that executes the script. A script is submitted by a request to a batch server. The *qsub* utility is a user-accessible batch client that submits a script.

Upon successful completion, the *qsub* utility shall have created a batch job that will execute the submitted script.

The *qsub* utility shall submit a script by sending a *Queue Job Request* to a batch server.

The *qsub* utility shall place the value of the following environment variables in the *Variable_List* attribute of the batch job: *HOME*, *LANG*, *LOGNAME*, *PATH*, *MAIL*, *SHELL*, and *TZ*. The name of the environment variable shall be the current name prefixed with the string PBS_O_.

Note: If the current value of the *HOME* variable in the environment space of the *qsub* utility is **/aa/bb/cc**, then *qsub* shall place *PBS_O_HOME*=**/aa/bb/cc** in the *Variable_List* attribute of the batch job.

In addition to the variables described above, the *qsub* utility shall add the following variables with the indicated values to the variable list:

PBS_O_WORKDIR The absolute path of the current working directory of the *qsub* utility process.

PBS_O_HOST The name of the host on which the *qsub* utility is running.

OPTIONS

The *qsub* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported by the implementation:

−**a** *date_time* Define the time at which a batch job becomes eligible for execution.

The *qsub* utility shall accept an option-argument that conforms to the syntax of the *time* operand of the *touch* utility.

106501 **Table 4-19** Environment Variable Values (Utilities)

Variable Name	Value at qsub Time
PBS_O_HOME	*HOME*
PBS_O_HOST	Client host name
PBS_O_LANG	*LANG*
PBS_O_LOGNAME	*LOGNAME*
PBS_O_PATH	*PATH*
PBS_O_MAIL	*MAIL*
PBS_O_SHELL	*SHELL*
PBS_O_TZ	*TZ*
PBS_O_WORKDIR	Current working directory

Note: The server that initiates execution of the batch job will add other variables to the batch job's environment; see Section 3.2.2.1 (on page 2433).

The *qsub* utility shall set the *Execution_Time* attribute of the batch job to the number of seconds since the Epoch that is equivalent to the local time expressed by the value of the *date_time* option-argument. The Epoch is defined in XBD Section 3.150 (on page 57).

If the **−a** option is not presented to the *qsub* utility, the utility shall set the *Execution_Time* attribute of the batch job to a time (number of seconds since the Epoch) that is earlier than the time at which the utility exits.

−A *account_string*

Define the account to which the resource consumption of the batch job should be charged.

The syntax of the *account_string* option-argument is unspecified.

The *qsub* utility shall set the *Account_Name* attribute of the batch job to the value of the *account_string* option-argument.

If the **−A** option is not presented to the *qsub* utility, the utility shall omit the *Account_Name* attribute from the attributes of the batch job.

−c *interval* Define whether the batch job should be checkpointed, and if so, how often.

The *qsub* utility shall accept a value for the interval option-argument that is one of the following:

`n` No checkpointing shall be performed on the batch job (NO_CHECKPOINT).

`s` Checkpointing shall be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).

`c` Automatic periodic checkpointing shall be performed at the *Minimum_Cpu_Interval* attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).

`c=`*minutes* Automatic periodic checkpointing shall be performed every *minutes* of CPU time, or every *Minimum_Cpu_Interval* minutes, whichever is greater. The *minutes* argument shall conform to the syntax for unsigned integers and shall be greater than zero.

The *qsub* utility shall set the *Checkpoint* attribute of the batch job to the value of the

106544 *interval* option-argument.

106545 If the **−c** option is not presented to the *qsub* utility, the utility shall set the *Checkpoint*
106546 attribute of the batch job to the single character `'u'`
106547 (CHECKPOINT_UNSPECIFIED).

106548 **−C** *directive_prefix*

106549 Define the prefix that declares a directive to the *qsub* utility within the script.

106550 The *directive_prefix* is not a batch job attribute; it affects the behavior of the *qsub*
106551 utility.

106552 If the **−C** option is presented to the *qsub* utility, and the value of the *directive_prefix*
106553 option-argument is the null string, the utility shall not scan the script file for
106554 directives. If the **−C** option is not presented to the *qsub* utility, then the value of the
106555 *PBS_DPREFIX* environment variable is used. If the environment variable is not
106556 defined, then #PBS encoded in the portable character set is the default.

106557 **−e** *path_name*

106558 Define the path to be used for the standard error stream of the batch job.

106559 The *qsub* utility shall accept a *path_name* option-argument which can be preceded
106560 by a host name element of the form *hostname*:.

106561 If the *path_name* option-argument constitutes an absolute pathname, the *qsub* utility
106562 shall set the *Error_Path* attribute of the batch job to the value of the *path_name*
106563 option-argument.

106564 If the *path_name* option-argument constitutes a relative pathname and no host
106565 name element is specified, the *qsub* utility shall set the *Error_Path* attribute of the
106566 batch job to the value of the absolute pathname derived by expanding the
106567 *path_name* option-argument relative to the current directory of the process
106568 executing *qsub*.

106569 If the *path_name* option-argument constitutes a relative pathname and a host name
106570 element is specified, the *qsub* utility shall set the *Error_Path* attribute of the batch
106571 job to the value of the *path_name* option-argument without expansion. The host
106572 name element shall be included.

106573 If the *path_name* option-argument does not include a host name element, the *qsub*
106574 utility shall prefix the pathname with *hostname*:, where *hostname* is the name of the
106575 host upon which the *qsub* utility is being executed.

106576 If the **−e** option is not presented to the *qsub* utility, the utility shall set the
106577 *Error_Path* attribute of the batch job to the host name and path of the current
106578 directory of the submitting process and the default filename.

106579 The default filename for standard error has the following format:

106580 `job_name.esequence_number`

106581 **−h** Specify that a USER hold is applied to the batch job.

106582 The *qsub* utility shall set the value of the *Hold_Types* attribute of the batch job to the
106583 value USER.

106584 If the **−h** option is not presented to the *qsub* utility, the utility shall set the
106585 *Hold_Types* attribute of the batch job to the value NO_HOLD.

106586 **–j** *join_list* Define which streams of the batch job are to be merged. The *qsub* **–j** option shall
106587 accept a value for the *join_list* option-argument that is a string of alphanumeric
106588 characters in the portable character set (see XBD Section 6.1, on page 125).

106589 The *qsub* utility shall accept a *join_list* option-argument that consists of one or more
106590 of the characters `'e'` and `'o'`, or the single character `'n'`.

106591 All of the other batch job output streams specified will be merged into the output
106592 stream represented by the character listed first in the *join_list* option-argument.

106593 For each unique character in the *join_list* option-argument, the *qsub* utility shall
106594 add a value to the *Join_Path* attribute of the batch job as follows, each representing
106595 a different batch job stream to join:

106596 `e` The standard error of the batch job (JOIN_STD_ERROR).

106597 `o` The standard output of the batch job (JOIN_STD_OUTPUT).

106598 An existing *Join_Path* attribute can be cleared by the following join type:

106599 `n` NO_JOIN

106600 If `'n'` is specified, then no files are joined. The *qsub* utility shall consider it an error
106601 if any join type other than `'n'` is combined with join type `'n'`.

106602 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
106603 `'n'` within the *join_list* option-argument. The *qsub* utility shall permit the
106604 repetition of characters, but shall not assign additional meaning to the repeated
106605 characters.

106606 An implementation may define other join types. The conformance document for an
106607 implementation shall describe any additional batch job streams, how they are
106608 specified, their internal behavior, and how they affect the behavior of the utility.

106609 If the **–j** option is not presented to the *qsub* utility, the utility shall set the value of
106610 the *Join_Path* attribute of the batch job to NO_JOIN.

106611 **–k** *keep_list* Define which output of the batch job to retain on the execution host.

106612 The *qsub* **–k** option shall accept a value for the *keep_list* option-argument that is a
106613 string of alphanumeric characters in the portable character set (see XBD Section
106614 6.1, on page 125).

106615 The *qsub* utility shall accept a *keep_list* option-argument that consists of one or
106616 more of the characters `'e'` and `'o'`, or the single character `'n'`.

106617 For each unique character in the *keep_list* option-argument, the *qsub* utility shall
106618 add a value to the *Keep_Files* attribute of the batch job as follows, each representing
106619 a different batch job stream to keep:

106620 `e` The standard error of the batch job (KEEP_STD_ERROR).

106621 `o` The standard output of the batch job (KEEP_STD_OUTPUT).

106622 If both `'e'` and `'o'` are specified, then both files are retained. An existing
106623 *Keep_Files* attribute can be cleared by the following keep type:

106624 `n` NO_KEEP

106625 If `'n'` is specified, then no files are retained. The *qsub* utility shall consider it an
106626 error if any keep type other than `'n'` is combined with keep type `'n'`.

106627 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
106628 `'n'` within the *keep_list* option-argument. The *qsub* utility shall permit the
106629 repetition of characters, but shall not assign additional meaning to the repeated
106630 characters.

106631 An implementation may define other keep types. The conformance document for
106632 an implementation shall describe any additional keep types, how they are
106633 specified, their internal behavior, and how they affect the behavior of the utility. If
106634 the **–k** option is not presented to the *qsub* utility, the utility shall set the *Keep_Files*
106635 attribute of the batch job to the value NO_KEEP.

106636 **–m** *mail_options*

106637 Define the points in the execution of the batch job at which the batch server that
106638 manages the batch job shall send mail about a change in the state of the batch job.

106639 The *qsub* **–m** option shall accept a value for the *mail_options* option-argument that
106640 is a string of alphanumeric characters in the portable character set (see XBD Section
106641 6.1, on page 125).

106642 The *qsub* utility shall accept a value for the *mail_options* option-argument that is a
106643 string of one or more of the characters `'e'`, `'b'`, and `'a'`, or the single character
106644 `'n'`.

106645 For each unique character in the *mail_options* option-argument, the *qsub* utility shall
106646 add a value to the *Mail_Users* attribute of the batch job as follows, each
106647 representing a different time during the life of a batch job at which to send mail:

106648 `e` MAIL_AT_EXIT

106649 `b` MAIL_AT_BEGINNING

106650 `a` MAIL_AT_ABORT

106651 If any of these characters are duplicated in the *mail_options* option-argument, the
106652 duplicates shall be ignored.

106653 An existing *Mail_Points* attribute can be cleared by the following mail type:

106654 `n` NO_MAIL

106655 If `'n'` is specified, then mail is not sent. The *qsub* utility shall consider it an error if
106656 any mail type other than `'n'` is combined with mail type `'n'`.

106657 Strictly conforming applications shall not repeat any of the characters `'e'`, `'b'`,
106658 `'a'`, or `'n'` within the *mail_options* option-argument.

106659 The *qsub* utility shall permit the repetition of characters, but shall not assign
106660 additional meaning to the repeated characters. An implementation may define
106661 other mail types. The conformance document for an implementation shall describe
106662 any additional mail types, how they are specified, their internal behavior, and how
106663 they affect the behavior of the utility.

106664 If the **–m** option is not presented to the *qsub* utility, the utility shall set the
106665 *Mail_Points* attribute to the value MAIL_AT_ABORT.

106666 **–M** *mail_list* Define the list of users to which a batch server that executes the batch job shall
106667 send mail, if the server sends mail about the batch job.

106668 The syntax of the *mail_list* option-argument is unspecified.

106669 If the implementation of the *qsub* utility uses a name service to locate users, the

106670 utility should accept the syntax used by the name service.

106671 106672 If the implementation of the *qsub* utility does not use a name service to locate users, the implementation should accept the following syntax for user names:

106673 *mail_address*`[,,`*mail_address*`,, ...]`

106674 The interpretation of *mail_address* is implementation-defined.

106675 106676 The *qsub* utility shall set the *Mail_Users* attribute of the batch job to the value of the *mail_list* option-argument.

106677 106678 106679 If the **−M** option is not presented to the *qsub* utility, the utility shall place only the user name and host name for the current process in the *Mail_Users* attribute of the batch job.

106680 **−N** *name* Define the name of the batch job.

106681 106682 106683 The *qsub* **−N** option shall accept a value for the *name* option-argument that is a string of up to 15 alphanumeric characters in the portable character set (see XBD Section 6.1, on page 125) where the first character is alphabetic.

106684 106685 The *qsub* utility shall set the value of the *Job_Name* attribute of the batch job to the value of the *name* option-argument.

106686 106687 106688 If the **−N** option is not presented to the *qsub* utility, the utility shall set the *Job_Name* attribute of the batch job to the name of the *script* argument from which the directory specification if any, has been removed.

106689 106690 106691 If the **−N** option is not presented to the *qsub* utility, and the script is read from standard input, the utility shall set the *Job_Name* attribute of the batch job to the value STDIN.

106692 **−o** *path_name*

106693 Define the path for the standard output of the batch job.

106694 106695 106696 106697 The *qsub* utility shall accept a *path_name* option-argument that conforms to the syntax of the *path_name* element defined in the System Interfaces volume of POSIX.1-2017, which can be preceded by a host name element of the form *hostname*:.

106698 106699 106700 If the *path_name* option-argument constitutes an absolute pathname, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion.

106701 106702 106703 106704 If the *path_name* option-argument constitutes a relative pathname and no host name element is specified, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the pathname derived by expanding the value of the *path_name* option-argument relative to the current directory of the process executing the *qsub*.

106705 106706 106707 If the *path_name* option-argument constitutes a relative pathname and a host name element is specified, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion.

106708 106709 106710 If the *path_name* option-argument does not specify a host name element, the *qsub* utility shall prefix the pathname with *hostname*:, where *hostname* is the name of the host upon which the *qsub* utility is executing.

106711 106712 If the **−o** option is not presented to the *qsub* utility, the utility shall set the *Output_Path* attribute of the batch job to the host name and path of the current

106713 directory of the submitting process and the default filename.

106714 The default filename for standard output has the following format:

106715 `job_name.osequence_number`

106716 −**p** *priority* Define the priority the batch job should have relative to other batch jobs owned by
106717 the batch server.

106718 The *qsub* utility shall set the *Priority* attribute of the batch job to the value of the
106719 *priority* option-argument.

106720 If the −**p** option is not presented to the *qsub* utility, the value of the *Priority* attribute
106721 is implementation-defined.

106722 The *qsub* utility shall accept a value for the *priority* option-argument that conforms
106723 to the syntax for signed decimal integers, and which is not less than −1 024 and not
106724 greater than 1 023.

106725 −**q** *destination*
106726 Define the destination of the batch job.

106727 The destination is not a batch job attribute; it determines the batch server, and
106728 possibly the batch queue, to which the *qsub* utility batch queues the batch job.

106729 The *qsub* utility shall submit the script to the batch server named by the *destination*
106730 option-argument or the server that owns the batch queue named in the *destination*
106731 option-argument.

106732 The *qsub* utility shall accept an option-argument for the −**q** option that conforms to
106733 the syntax for a destination (see Section 3.3.2, on page 2450).

106734 If the −**q** option is not presented to the *qsub* utility, the *qsub* utility shall submit the
106735 batch job to the default destination. The mechanism for determining the default
106736 destination is implementation-defined.

106737 −**r** *y* | *n* Define whether the batch job is rerunnable.

106738 If the value of the option-argument is *y*, the *qsub* utility shall set the *Rerunable*
106739 attribute of the batch job to TRUE.

106740 If the value of the option-argument is *n*, the *qsub* utility shall set the *Rerunable*
106741 attribute of the batch job to FALSE.

106742 If the −**r** option is not presented to the *qsub* utility, the utility shall set the *Rerunable*
106743 attribute of the batch job to TRUE.

106744 −**S** *path_name_list*
106745 Define the pathname to the shell under which the batch job is to execute.

106746 The *qsub* utility shall accept a *path_name_list* option-argument that conforms to the
106747 following syntax:

106748 `pathname[@host][,,pathname[@host],, ...]`

106749 The *qsub* utility shall allow only one pathname for a given host name. The *qsub*
106750 utility shall allow only one pathname that is missing a corresponding host name.

106751 The *qsub* utility shall add a value to the *Shell_Path_List* attribute of the batch job for
106752 each entry in the *path_name_list* option-argument.

106753 If the −**S** option is not presented to the *qsub* utility, the utility shall set the

106754 *Shell_Path_List* attribute of the batch job to the null string.

106755 The conformance document for an implementation shall describe the mechanism
106756 used to set the default shell and determine the current value of the default shell.
106757 An implementation shall provide a means for the installation to set the default
106758 shell to the login shell of the user under which the batch job is to execute. See
106759 Section 3.3.3 (on page 2451) for a means of removing *keyword=value* (and
106760 *value@keyword*) pairs and other general rules for list-oriented batch job attributes.

106761 **−u** *user_list* Define the user name under which the batch job is to execute.

106762 The *qsub* utility shall accept a *user_list* option-argument that conforms to the
106763 following syntax:

106764 `username[@host][,,username[@host],, ...]`

106765 The *qsub* utility shall accept only one user name that is missing a corresponding
106766 host name. The *qsub* utility shall accept only one user name per named host.

106767 The *qsub* utility shall add a value to the *User_List* attribute of the batch job for each
106768 entry in the *user_list* option-argument.

106769 If the **−u** option is not presented to the *qsub* utility, the utility shall set the *User_List*
106770 attribute of the batch job to the user name from which the utility is executing. See
106771 Section 3.3.3 (on page 2451) for a means of removing *keyword=value* (and
106772 *value@keyword*) pairs and other general rules for list-oriented batch job attributes.

106773 **−v** *variable_list*
106774 Add to the list of variables that are exported to the session leader of the batch job.

106775 A *variable_list* is a set of strings of either the form <*variable*> or <*variable=value*>,
106776 delimited by <comma> characters.

106777 If the **−v** option is presented to the *qsub* utility, the utility shall also add, to the
106778 environment *Variable_List* attribute of the batch job, every variable named in the
106779 environment *variable_list* option-argument and, optionally, values of specified
106780 variables.

106781 If a value is not provided on the command line, the *qsub* utility shall set the value
106782 of each variable in the environment *Variable_List* attribute of the batch job to the
106783 value of the corresponding environment variable for the process in which the
106784 utility is executing; see Table 4-19 (on page 3179).

106785 A conforming application shall not repeat a variable in the environment
106786 *variable_list* option-argument.

106787 The *qsub* utility shall not repeat a variable in the environment *Variable_List* attribute
106788 of the batch job. See Section 3.3.3 (on page 2451) for a means of removing
106789 *keyword=value* (and *value@keyword*) pairs and other general rules for list-oriented
106790 batch job attributes.

106791 **−V** Specify that all of the environment variables of the process are exported to the
106792 context of the batch job.

106793 The *qsub* utility shall place every environment variable in the process in which the
106794 utility is executing in the list and shall set the value of each variable in the attribute
106795 to the value of that variable in the process.

106796 **−z** Specify that the utility does not write the batch *job_identifier* of the created batch job
106797 to standard output.

106798 If the **−z** option is presented to the *qsub* utility, the utility shall not write the batch
106799 *job_identifier* of the created batch job to standard output.

106800 If the **−z** option is not presented to the *qsub* utility, the utility shall write the
106801 identifier of the created batch job to standard output.

106802 **OPERANDS**

106803 The *qsub* utility shall accept a *script* operand that indicates the path to the script of the batch job.

106804 If the *script* operand is not presented to the *qsub* utility, or if the operand is the single-character
106805 string `'−'`, the utility shall read the script from standard input.

106806 If the script represents a partial path, the *qsub* utility shall expand the path relative to the current
106807 directory of the process executing the utility.

106808 **STDIN**

106809 The *qsub* utility reads the script of the batch job from standard input if the script operand is
106810 omitted or is the single character `'−'`.

106811 **INPUT FILES**

106812 In addition to binding the file indicated by the *script* operand to the batch job, the *qsub* utility
106813 reads the script file and acts on directives in the script.

106814 **ENVIRONMENT VARIABLES**

106815 The following environment variables shall affect the execution of *qsub*:

106816 *LANG* Provide a default value for the internationalization variables that are unset or null.
106817 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
106818 used to determine the values of locale categories.)

106819 *LC_ALL* If set to a non-empty string value, override the values of all the other
106820 internationalization variables.

106821 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
106822 characters (for example, single-byte as opposed to multi-byte characters in
106823 arguments).

106824 *LC_MESSAGES*
106825 Determine the locale that should be used to affect the format and contents of
106826 diagnostic messages written to standard error.

106827 *LOGNAME* Determine the login name of the user.

106828 *PBS_DPREFIX*
106829 Determine the default prefix for directives within the script.

106830 *SHELL* Determine the pathname of the preferred command language interpreter of the
106831 user.

106832 *TZ* Determine the timezone used to interpret the *date-time* option-argument. If *TZ* is
106833 unset or null, an unspecified default timezone shall be used.

106834 **ASYNCHRONOUS EVENTS**

106835 Once created, a batch job exists until it exits, aborts, or is deleted.

106836 After a batch job is created by the *qsub* utility, batch servers might route, execute, modify, or
106837 delete the batch job.

106838 **STDOUT**

106839 The *qsub* utility writes the batch *job_identifier* assigned to the batch job to standard output, unless
106840 the −**z** option is specified.

106841 **STDERR**

106842 The standard error shall be used only for diagnostic messages.

106843 **OUTPUT FILES**

106844 None.

106845 **EXTENDED DESCRIPTION**

106846 **Script Preservation**

106847 The *qsub* utility shall make the script available to the server executing the batch job in such a
106848 way that the server executes the script as it exists at the time of submission.

106849 The *qsub* utility can send a copy of the script to the server with the *Queue Job Request* or store a
106850 temporary copy of the script in a location specified to the server.

106851 **Option Specification**

106852 A script can contain directives to the *qsub* utility.

106853 The *qsub* utility shall scan the lines of the script for directives, skipping blank lines, until the first
106854 line that begins with a string other than the directive string; if directives occur on subsequent
106855 lines, the utility shall ignore those directives.

106856 Lines are separated by a <newline>. If the first line of the script begins with `"#!"` or a <colon>
106857 (`':'`), then it is skipped. The *qsub* utility shall process a line in the script as a directive if and
106858 only if the string of characters from the first non-white-space character on the line until the first
106859 <space> or <tab> on the line match the directive prefix. If a line in the script contains a directive
106860 and the final characters of the line are <backslash> and <newline>, then the next line shall be
106861 interpreted as a continuation of that directive.

106862 The *qsub* utility shall process the options and option-arguments contained on the directive prefix
106863 line using the same syntax as if the options were input on the *qsub* utility.

106864 The *qsub* utility shall continue to process a directive prefix line until after a <newline> is
106865 encountered. An implementation may ignore lines which, according to the syntax of the shell
106866 that will interpret the script, are comments. An implementation shall describe in the
106867 conformance document the format of any shell comments that it will recognize.

106868 If an option is present in both a directive and the arguments to the *qsub* utility, the utility shall
106869 ignore the option and the corresponding option-argument, if any, in the directive.

106870 If an option that is present in the directive is not present in the arguments to the *qsub* utility, the
106871 utility shall process the option and the option-argument, if any.

106872 In order of preference, the *qsub* utility shall select the directive prefix from one of the following
106873 sources:

106874 If the −**C** option is presented to the utility, the value of the *directive_prefix* option-argument

106875 If the environment variable *PBS_DPREFIX* is defined, the value of that variable

106876 The four-character string `"#PBS"` encoded in the portable character set

106877 If the −**C** option is present in the script file it shall be ignored.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qsub* utility allows users to create a batch job that will process the script specified as the operand of the utility.

The options of the *qsub* utility allow users to control many aspects of the queuing and execution of a batch job.

The **−a** option allows users to designate the time after which the batch job will become eligible to run. By specifying an execution time, users can take advantage of resources at off-peak hours, synchronize jobs with chronologically predictable events, and perhaps take advantage of off-peak pricing of computing time. For these reasons and others, a timing option is existing practice on the part of almost every batch system, including NQS.

The **−A** option allows users to specify the account that will be charged for the batch job. Support for account is not mandatory for conforming batch servers.

The **−C** option allows users to prescribe the prefix for directives within the script file. The default prefix `"#PBS"` may be inappropriate if the script will be interpreted with an alternate shell, as specified by the **−S** option.

The **−c** option allows users to establish the checkpointing interval for their jobs. A checkpointing system, which is not defined by this volume of POSIX.1-2017, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of POSIX.1-2017 provides the checkpointing interval option. Support for checkpointing is optional for batch servers.

The **−e** option allows users to redirect the standard error streams of their jobs to a non-default path. For example, if the submitted script generally produces a great deal of useless error output, a user might redirect the standard error output to the null device. Or, if the file system holding the default location (the home directory of the user) has too little free space, the user might redirect the standard error stream to a file in another file system.

The **−h** option allows users to create a batch job that is held until explicitly released. The ability to create a held job is useful when some external event must complete before the batch job can execute. For example, the user might submit a held job and release it when the system load has dropped.

The **−j** option allows users to merge the standard error of a batch job into its standard output stream, which has the advantage of showing the sequential relationship between output and error messages.

The **−m** option allows users to designate those points in the execution of a batch job at which mail will be sent to the submitting user, or to the account(s) indicated by the **−M** option. By requesting mail notification at points of interest in the life of a job, the submitting user, or other designated users, can track the progress of a batch job.

The **−N** option allows users to associate a name with the batch job. The job name in no way affects the processing of the batch job, but rather serves as a mnemonic handle for users. For example, the batch job name can help the user distinguish between multiple jobs listed by the *qstat* utility.

The **−o** option allows users to redirect the standard output stream. A user might, for example, wish to redirect to the null device the standard output stream of a job that produces copious yet superfluous output.

The **−P** option allows users to designate the relative priority of a batch job for selection from a queue.

The **−q** option allows users to specify an initial queue for the batch job. If the user specifies a routing queue, the batch server routes the batch job to another queue for execution or further routing. If the user specifies a non-routing queue, the batch server of the queue eventually executes the batch job.

The **−r** option allows users to control whether the submitted job will be rerun if the controlling batch node fails during execution of the batch job. The **−r** option likewise allows users to indicate whether or not the batch job is eligible to be rerun by the *qrerun* utility. Some jobs cannot be correctly rerun because of changes they make in the state of databases or other aspects of their environment. This volume of POSIX.1-2017 specifies that the default, if the **−r** option is not presented to the utility, will be that the batch job cannot be rerun, since the result of rerunning a non-rerunnable job might be catastrophic.

The **−S** option allows users to specify the program (usually a shell) that will be invoked to process the script of the batch job. This option has been modified to allow a list of shell names and locations associated with different hosts.

The **−u** option is useful when the submitting user is authorized to use more than one account on a given host, in which case the **−u** option allows the user to select from among those accounts. The option-argument is a list of user-host pairs, so that the submitting user can provide different user identifiers for different nodes in the event the batch job is routed. The **−u** option provides a lot of flexibility to accommodate sites with complex account structures. Users that have the same user identifier on all the hosts they are authorized to use will not need to use the **−u** option.

The **−V** option allows users to export all their current environment variables, as of the time the batch job is submitted, to the context of the processes of the batch job.

The **−v** option allows users to export specific environment variables from their current process to the processes of the batch job.

The **−z** option allows users to suppress the writing of the batch job identifier to standard output. The **−z** option is an existing NQS practice that has been standardized.

Historically, the *qsub* utility has served the batch job-submission function in the NQS system, the existing practice on which it is based. Some changes and additions have been made to the *qsub* utility in this volume of POSIX.1-2017, *vis-a-vis* NQS, as a result of the growing pool of experience with distributed batch systems.

The set of features of the *qsub* utility as defined in this volume of POSIX.1-2017 appears to incorporate all the common existing practice on potentially conforming platforms.

FUTURE DIRECTIONS

The *qsub* utility may be removed in a future version.

XBD Section 3.150 (on page 57), Section 6.1 (on page 125), Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The **–l** option has been removed as there is no portable description of the resources that are allowed or required by the batch job.

Issue 7

The *qsub* utility is marked obsolescent.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

read — read from standard input into shell variables

SYNOPSIS

```
read [−r] var...
```

DESCRIPTION

The *read* utility shall read a single logical line from standard input into one or more shell variables.

By default, unless the **−r** option is specified, <backslash> shall act as an escape character. An unescaped <backslash> shall preserve the literal value of the following character, with the exception of a <newline>. If a <newline> follows the <backslash>, the *read* utility shall interpret this as line continuation. The <backslash> and <newline> shall be removed before splitting the input into fields. All other unescaped <backslash> characters shall be removed after splitting the input into fields.

If standard input is a terminal device and the invoking shell is interactive, *read* shall prompt for a continuation line when it reads an input line ending with a <backslash> <newline>, unless the **−r** option is specified.

The terminating <newline> (if any) shall be removed from the input and the results shall be split into fields as in the shell for the results of parameter expansion (see Section 2.6.5, on page 2359); the first field shall be assigned to the first variable *var*, the second field to the second variable *var*, and so on. If there are fewer fields than there are *var* operands, the remaining *var*s shall be set to empty strings. If there are fewer *var*s than fields, the last *var* shall be set to a value comprising the following elements:

The field that corresponds to the last *var* in the normal assignment sequence described above

The delimiter(s) that follow the field corresponding to the last *var*

The remaining fields and their delimiters, with trailing *IFS* white space ignored

The setting of variables specified by the *var* operands shall affect the current shell execution environment; see Section 2.12 (on page 2381). If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . −exec read ... \;
```

it shall not affect the shell variables in the caller's environment.

OPTIONS

The *read* utility shall conform to XBD Section 12.2 (on page 216).

The following option is supported:

−r Do not treat a <backslash> character in any special way. Consider each <backslash> to be part of the input line.

OPERANDS

The following operand shall be supported:

var The name of an existing or nonexisting shell variable.

STDIN

The standard input shall be a text file.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *read*:

IFS Determine the internal field separators used to delimit fields; see Section 2.5.3 (on page 2351).

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PS2 Provide the prompt string that an interactive shell shall write to standard error when a line ending with a <backslash> <newline> is read and the **−r** option was not specified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic messages and prompts for continued input.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 End-of-file was detected or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **−r** option is included to enable *read* to subsume the purpose of the *line* utility, which is not included in POSIX.1-2017.

EXAMPLES

The following command:

```
while read −r xx yy
do
    printf "%s %s\n" "$yy" "$xx"
done < input_file
```

prints a file with the first field of each line moved to the end of the line.

RATIONALE

The *read* utility historically has been a shell built-in. It was separated off into its own utility to take advantage of the richer description of functionality introduced by this volume of POSIX.1-2017.

Since *read* affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . −exec read ... \;
```

it does not affect the shell variables in the environment of the caller.

Although the standard input is required to be a text file, and therefore will always end with a <newline> (unless it is an empty file), the processing of continuation lines when the **−r** option is not used can result in the input not ending with a <newline>. This occurs if the last line of the input file ends with a <backslash> <newline>. It is for this reason that ``if any'' is used in ``The terminating <newline> (if any) shall be removed from the input'' in the description. It is not a relaxation of the requirement for standard input to be a text file.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 7

Austin Group Interpretation 1003.1-2001 #194 is applied, clarifying the handling of the <backslash> escape character.

SD5-XCU-ERN-126 is applied, clarifying that input lines end with a <newline>.

The description of here-documents is removed from the *read* reference page.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0162 [958] is applied.

NAME

renice — set nice values of running processes

SYNOPSIS

```
renice [-g|-p|-u] -n increment ID...
```

DESCRIPTION

The *renice* utility shall request that the nice values (see XBD Section 3.244, on page 72) of one or more running processes be changed. By default, the applicable processes are specified by their process IDs. When a process group is specified (see **-g**), the request shall apply to all processes in the process group.

The nice value shall be bounded in an implementation-defined manner. If the requested *increment* would raise or lower the nice value of the executed utility beyond implementation-defined limits, then the limit whose value was exceeded shall be used.

When a user is *renice*d, the request applies to all processes whose saved set-user-ID matches the user ID corresponding to the user.

Regardless of which options are supplied or any other factor, *renice* shall not alter the nice values of any process unless the user requesting such a change has appropriate privileges to do so for the specified process. If the user lacks appropriate privileges to perform the requested action, the utility shall return an error status.

The saved set-user-ID of the user's process shall be checked instead of its effective user ID when *renice* attempts to determine the user ID of the process in order to determine whether the user has appropriate privileges.

OPTIONS

The *renice* utility shall conform to XBD Section 12.2 (on page 216), except for Guideline 9.

The following options shall be supported:

-g Interpret the following operands as unsigned decimal integer process group IDs.

-n *increment* Specify how the nice value of the specified process or processes is to be adjusted. The *increment* option-argument is a positive or negative decimal integer that shall be used to modify the nice value of the specified process or processes.

Positive *increment* values shall cause a lower nice value. Negative *increment* values may require appropriate privileges and shall cause a higher nice value.

-p Interpret the following operands as unsigned decimal integer process IDs. The **-p** option is the default if no options are specified.

-u Interpret the following operands as users. If a user exists with a user name equal to the operand, then the user ID of that user is used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it shall be used as the numeric user ID of the user.

OPERANDS

The following operands shall be supported:

ID A process ID, process group ID, or user name/user ID, depending on the option selected.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *renice*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Adjust the nice value so that process IDs 987 and 32 would have a lower nice value:

```
renice -n 5 -p 987 32
```

2. Adjust the nice value so that group IDs 324 and 76 would have a higher nice value, if the user has appropriate privileges to do so:

```
renice -n -4 -g 324 76
```

3. Adjust the nice value so that numeric user ID 8 and user **sas** would have a lower nice value:

```
renice -n 4 -u 8 sas
```

Useful nice value increments on historical systems include 19 or 20 (the affected processes run only when nothing else in the system attempts to run) and any negative number (to make processes run faster).

RATIONALE

The *gid*, *pid*, and *user* specifications do not fit either the definition of operand or option-argument. However, for clarity, they have been included in the OPTIONS section, rather than the OPERANDS section.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of POSIX.1-2017 make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of POSIX.1-2017, and others may have no effect at all. Because of the use of ``implementation-defined'' in *nice* and *renice*, a wide range of implementation strategies are possible.

Originally, this utility was written in the historical manner, using the term ``nice value''. This was always a point of concern with users because it was never intuitively obvious what this meant. With a newer version of *renice*, which used the term ``system scheduling priority'', it was hoped that novice users could better understand what this utility was meant to do. Also, it would be easier to document what the utility was meant to do. Unfortunately, the addition of the POSIX realtime scheduling capabilities introduced the concepts of process and thread scheduling priorities that were totally unaffected by the *nice*/*renice* utilities or the *nice*()/*setpriority*() functions. Continuing to use the term ``system scheduling priority'' would have incorrectly suggested that these utilities and functions were indeed affecting these realtime priorities. It was decided to revert to the historical term ``nice value'' to reference this unrelated process attribute.

Although this utility has use by system administrators (and in fact appears in the system administration portion of the BSD documentation), the standard developers considered that it was very useful for individual end users to control their own processes.

Earlier versions of this standard allowed the following forms in the SYNOPSIS:

```
renice nice_value[-p] pid...[-g gid...][-p pid...][-u user...]
renice nice_value -g gid...[-g gid...]-p pid...][-u user...]
renice nice_value -u user...[-g gid...]-p pid...][-u user...]
```

These forms are no longer specified by POSIX.1-2017 but may be present in some implementations.

FUTURE DIRECTIONS

None.

SEE ALSO

nice

CHANGE HISTORY

First released in Issue 4.

Issue 5

In the SYNOPSIS, an ellipsis is added to the **−u** option in all three obsolescent forms.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent forms of the SYNOPSIS are removed.

Text previously conditional on POSIX_SAVED_IDS is mandatory in this version. This is a FIPS requirement.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *renice* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

rm — remove directory entries

SYNOPSIS

```
rm [−iRr] file...
rm −f [−iRr] [file...]
```

DESCRIPTION

The *rm* utility shall remove the directory entry specified by each *file* argument.

If either of the files dot or dot-dot are specified as the basename portion of an operand (that is, the final pathname component) or if an operand resolves to the root directory, *rm* shall write a diagnostic message to standard error and do nothing more with such operands.

For each *file* the following steps shall be taken:

1. If the *file* does not exist:
   a. If the **−f** option is not specified, *rm* shall write a diagnostic message to standard error.
   b. Go on to any remaining *files*.
2. If *file* is of type directory, the following steps shall be taken:
   a. If neither the **−R** option nor the **−r** option is specified, *rm* shall write a diagnostic message to standard error, do nothing more with *file*, and go on to any remaining files.
   b. If *file* is an empty directory, *rm* may skip to step 2d. If the **−f** option is not specified, and either the permissions of *file* do not permit writing and the standard input is a terminal or the **−i** option is specified, *rm* shall write a prompt to standard error and read a line from the standard input. If the response is not affirmative, *rm* shall do nothing more with the current file and go on to any remaining files.
   c. For each entry contained in *file*, other than dot or dot-dot, the four steps listed here (1 to 4) shall be taken with the entry as if it were a *file* operand. The *rm* utility shall not traverse directories by following symbolic links into other parts of the hierarchy, but shall remove the links themselves.
   d. If the **−i** option is specified, *rm* shall write a prompt to standard error and read a line from the standard input. If the response is not affirmative, *rm* shall do nothing more with the current file, and go on to any remaining files.
3. If *file* is not of type directory, the **−f** option is not specified, and either the permissions of *file* do not permit writing and the standard input is a terminal or the **−i** option is specified, *rm* shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, *rm* shall do nothing more with the current file and go on to any remaining files.
4. If the current file is a directory, *rm* shall perform actions equivalent to the *rmdir*( ) function defined in the System Interfaces volume of POSIX.1-2017 called with a pathname of the current file used as the *path* argument. If the current file is not a directory, *rm* shall perform actions equivalent to the *unlink*( ) function defined in the System Interfaces volume of POSIX.1-2017 called with a pathname of the current file used as the *path* argument.

   If this fails for any reason, *rm* shall write a diagnostic message to standard error, do nothing more with the current file, and go on to any remaining files.

The *rm* utility shall be able to descend to arbitrary depths in a file hierarchy, and shall not fail due to path length limitations (unless an operand specified by the user exceeds system limitations).

OPTIONS

The *rm* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−f Do not prompt for confirmation. Do not write diagnostic messages or modify the exit status in the case of no file operands, or in the case of operands that do not exist. Any previous occurrences of the **−i** option shall be ignored.

−i Prompt for confirmation as described previously. Any previous occurrences of the **−f** option shall be ignored.

−R Remove file hierarchies. See the DESCRIPTION.

−r Equivalent to **−R**.

OPERANDS

The following operand shall be supported:

file A pathname of a directory entry to be removed.

STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDOUT section. Otherwise, the standard input shall not be used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rm*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages and prompts written to standard error.

107327 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

107328 **ASYNCHRONOUS EVENTS**
107329 Default.

107330 **STDOUT**
107331 Not used.

107332 **STDERR**
107333 Prompts shall be written to standard error under the conditions specified in the DESCRIPTION
107334 and OPTIONS sections. The prompts shall contain the *file* pathname, but their format is
107335 otherwise unspecified. The standard error also shall be used for diagnostic messages.

107336 **OUTPUT FILES**
107337 None.

107338 **EXTENDED DESCRIPTION**
107339 None.

107340 **EXIT STATUS**
107341 The following exit values shall be returned:

107342 0 Each directory entry was successfully removed, unless its removal was canceled by a non-
107343 affirmative response to a prompt for confirmation.

107344 >0 An error occurred.

107345 **CONSEQUENCES OF ERRORS**
107346 Default.

107347 **APPLICATION USAGE**
107348 The *rm* utility is forbidden to remove the names dot and dot-dot in order to avoid the
107349 consequences of inadvertently doing something like:

107350 `rm -r .*`

107351 Some implementations do not permit the removal of the last link to an executable binary file that
107352 is being executed; see the [EBUSY] error in the *unlink*( ) function defined in the System Interfaces
107353 volume of POSIX.1-2017. Thus, the *rm* utility can fail to remove such files.

107354 The **–i** option causes *rm* to prompt and read the standard input even if the standard input is not
107355 a terminal, but in the absence of **–i** the mode prompting is not done when the standard input is
107356 not a terminal.

107357 **EXAMPLES**

107358 1. The following command:

107359 `rm a.out core`

107360 removes the directory entries: **a.out** and **core**.

107361 2. The following command:

107362 `rm -Rf junk`

107363 removes the directory **junk** and all its contents, without prompting.

107364 **RATIONALE**
107365 For absolute clarity, paragraphs (2b) and (3) in the DESCRIPTION of *rm* describing the behavior
107366 when prompting for confirmation, should be interpreted in the following manner:

107367 `if ((NOT f_option) AND`

```
((not_writable AND input_is_terminal) OR i_option))
```

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the **−f** option, or using the **−i** option, relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The **−r** option is historical practice on all known systems. The synonym **−R** option is provided for consistency with the other utilities in this volume of POSIX.1-2017 that provide options requesting recursive descent through the file hierarchy.

The behavior of the **−f** option in historical versions of *rm* is inconsistent. In general, along with ``forcing'' the unlink without prompting for permission, it always causes diagnostic messages to be suppressed and the exit status to be unmodified for nonexistent operands and files that cannot be unlinked. In some versions, however, the **−f** option suppresses usage messages and system errors as well. Suppressing such messages is not a service to either shell scripts or users.

It is less clear that error messages regarding files that cannot be unlinked (removed) should be suppressed. Although this is historical practice, this volume of POSIX.1-2017 does not permit the **−f** option to suppress such messages.

When given the **−r** and **−i** options, historical versions of *rm* prompt the user twice for each directory, once before removing its contents and once before actually attempting to delete the directory entry that names it. This allows the user to ``prune'' the file hierarchy walk. Historical versions of *rm* were inconsistent in that some did not do the former prompt for directories named on the command line and others had obscure prompting behavior when the **−i** option was specified and the permissions of the file did not permit writing. The POSIX Shell and Utilities *rm* differs little from historic practice, but does require that prompts be consistent. Historical versions of *rm* were also inconsistent in that prompts were done to both standard output and standard error. This volume of POSIX.1-2017 requires that prompts be done to standard error, for consistency with *cp* and *mv*, and to allow historical extensions to *rm* that provide an option to list deleted files on standard output.

The *rm* utility is required to descend to arbitrary depths so that any file hierarchy may be deleted. This means, for example, that the *rm* utility cannot run out of file descriptors during its descent (that is, if the number of file descriptors is limited, *rm* cannot be implemented in the historical fashion where one file descriptor is used per directory level). Also, *rm* is not permitted to fail because of path length restrictions, unless an operand specified by the user is longer than {PATH_MAX}.

The *rm* utility removes symbolic links themselves, not the files they refer to, as a consequence of the dependence on the *unlink*() functionality, per the DESCRIPTION. When removing hierarchies with **−r** or **−R**, the prohibition on following symbolic links has to be made explicit.

FUTURE DIRECTIONS

None.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0163 [542], XCU/TC2-2008/0164 [819], and XCU/TC2-2008/0165 [542] are applied.

NAME

rmdel — remove a delta from an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI

```
rmdel −r SID file...
```

DESCRIPTION

The *rmdel* utility shall remove the delta specified by the SID from each named SCCS file. The delta to be removed shall be the most recent delta in its branch in the delta chain of each named SCCS file. In addition, the application shall ensure that the SID specified is not that of a version being edited for the purpose of making a delta; that is, if a *p-file* (see *get*) exists for the named SCCS file, the SID specified shall not appear in any entry of the *p-file*.

Removal of a delta shall be restricted to:

1. The user who made the delta
2. The owner of the SCCS file
3. The owner of the directory containing the SCCS file

OPTIONS

The *rmdel* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−r *SID* Specify the SCCS identification string (*SID*) of the delta to be deleted.

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *rmdel* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

The SCCS files shall be files of unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rmdel*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
The SCCS files shall be files of unspecified format. During processing of a *file*, a temporary *x-file*, as described in *admin*, may be created and deleted; a locking *z-file*, as described in *get*, may be created and deleted.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
None.

EXAMPLES
None.

RATIONALE
None.

FUTURE DIRECTIONS

NAME

rmdir — remove directories

SYNOPSIS

```
rmdir [−p] dir...
```

DESCRIPTION

The *rmdir* utility shall remove the directory entry specified by each *dir* operand.

For each *dir* operand, the *rmdir* utility shall perform actions equivalent to the *rmdir*( ) function called with the *dir* operand as its only argument.

Directories shall be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of the *rmdir* utility, the application shall specify the subdirectory before the parent directory so that the parent directory will be empty when the *rmdir* utility tries to remove it.

OPTIONS

The *rmdir* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−p Remove all directories in a pathname. For each *dir* operand:

1. The directory entry it names shall be removed.
2. If the *dir* operand includes more than one pathname component, effects equivalent to the following command shall occur:

   ```
   rmdir −p $(dirname dir)
   ```

OPERANDS

The following operand shall be supported:

dir A pathname of an empty directory to be removed.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rmdir*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

107543 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

107544 **ASYNCHRONOUS EVENTS**
107545 Default.

107546 **STDOUT**
107547 Not used.

107548 **STDERR**
107549 The standard error shall be used only for diagnostic messages.

107550 **OUTPUT FILES**
107551 None.

107552 **EXTENDED DESCRIPTION**
107553 None.

107554 **EXIT STATUS**
107555 The following exit values shall be returned:

107556 0 Each directory entry specified by a *dir* operand was removed successfully.

107557 >0 An error occurred.

107558 **CONSEQUENCES OF ERRORS**
107559 Default.

107560 **APPLICATION USAGE**
107561 The definition of an empty directory is one that contains, at most, directory entries for dot and
107562 dot-dot.

107563 **EXAMPLES**
107564 If a directory **a** in the current directory is empty except it contains a directory **b** and **a/b** is empty
107565 except it contains a directory **c**:

107566 `rmdir -p a/b/c`

107567 removes all three directories.

107568 **RATIONALE**
107569 On historical System V systems, the **-p** option also caused a message to be written to the
107570 standard output. The message indicated whether the whole path was removed or whether part
107571 of the path remained for some reason. The STDERR section requires this diagnostic when the
107572 entire path specified by a *dir* operand is not removed, but does not allow the status message
107573 reporting success to be written as a diagnostic.

107574 The *rmdir* utility on System V also included a **-s** option that suppressed the informational
107575 message output by the **-p** option. This option has been omitted because the informational
107576 message is not specified by this volume of POSIX.1-2017.

107577 **FUTURE DIRECTIONS**
107578 None.

107579 **SEE ALSO**

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

NAME

sact — print current SCCS file-editing activity (**DEVELOPMENT**)

SYNOPSIS

XSI

```
sact file...
```

DESCRIPTION

The *sact* utility shall inform the user of any impending deltas to a named SCCS file by writing a list to standard output. This situation occurs when *get* **−e** has been executed previously without a subsequent execution of *delta*, *unget*, or *sccs* **unedit**.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *sact* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

Any SCCS files interrogated are files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sact*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output for each named file shall consist of a line in the following format:

`"%sΔ%sΔ%sΔ%sΔ%s\n", <SID>, <new SID>, <login>, <date>, <time>`

<SID> Specifies the SID of a delta that currently exists in the SCCS file to which changes are made to make the new delta.

<new SID> Specifies the SID for the new delta to be created.

<login> Contains the login name of the user who makes the delta (that is, who executed a *get* for editing).

<date> Contains the date that *get* **−e** was executed, in the format used by the *prs* **:D:** data keyword.

<time> Contains the time that *get* **−e** was executed, in the format used by the *prs* **:T:** data keyword.

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:

`"\n%s:\n", <pathname>`

STDERR

The standard error shall be used only for optional informative messages concerning SCCS files with no impending deltas, and for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 2.

NAME

sccs — front end for the SCCS subsystem (**DEVELOPMENT**)

SYNOPSIS

XSI
```
sccs [−r] [−d path] [−p path] command [options...] [operands...]
```

DESCRIPTION

The *sccs* utility is a front end to the SCCS programs. It also includes the capability to run set-user-id to another user to provide additional protection.

The *sccs* utility shall invoke the specified *command* with the specified *options* and *operands*. By default, each of the *operands* shall be modified by prefixing it with the string "`SCCS/s.`".

The *command* can be the name of one of the SCCS utilities in this volume of POSIX.1-2017 (*admin*, *delta*, *get*, *prs*, *rmdel*, *sact*, *unget*, *val*, or *what*) or one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.

OPTIONS

The *sccs* utility shall conform to XBD Section 12.2 (on page 216), except that *options* operands are actually options to be passed to the utility named by *command*. When the portion of the command:

```
command [options ... ] [operands ... ]
```

is considered, all of the pseudo-utilities used as *command* shall support the Utility Syntax Guidelines. Any of the other SCCS utilities that can be invoked in this manner support the Guidelines to the extent indicated by their individual OPTIONS sections.

The following options shall be supported preceding the *command* operand:

−d *path* A pathname of a directory to be used as a root directory for the SCCS files. The default shall be the current directory. The **−d** option shall take precedence over the *PROJECTDIR* variable. See **−p**.

−p *path* A pathname of a directory in which the SCCS files are located. The default shall be the **SCCS** directory.

The **−p** option differs from the **−d** option in that the **−d** option-argument shall be prefixed to the entire pathname and the **−p** option-argument shall be inserted before the final component of the pathname. For example:

```
sccs −d /x −p y get a/b
```

converts to:

```
get /x/a/y/s.b
```

This allows the creation of aliases such as:

```
alias syssccs="sccs −d /usr/src"
```

which is used as:

```
syssccs get cmd/who.c
```

−r Invoke *command* with the real user ID of the process, not any effective user ID that the *sccs* utility is set to. Certain commands (*admin*, **check**, **clean**, **diffs**, **info**, *rmdel*, and **tell**) cannot be run set-user-ID by all users, since this would allow anyone to change the authorizations. These commands are always run as the real user.

OPERANDS

The following operands shall be supported:

command An SCCS utility name or the name of one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.

options An option or option-argument to be passed to *command*.

operands An operand to be passed to *command*.

STDIN

See the utility description for the specified *command*.

INPUT FILES

See the utility description for the specified *command*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sccs*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PROJECTDIR
Provide a default value for the **−d** *path* option. If the value of *PROJECTDIR* begins with a <slash>, it shall be considered an absolute pathname; otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory shall be examined for a subdirectory **src** or **source**. If such a directory is found, it shall be used. Otherwise, the value shall be used as a relative pathname.

Additional environment variable effects may be found in the utility description for the specified *command*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the utility description for the specified *command*.

STDERR

See the utility description for the specified *command*.

OUTPUT FILES

See the utility description for the specified *command*.

EXTENDED DESCRIPTION

The following pseudo-utilities shall be supported as *command* operands. All options referred to in the following list are values given in the *options* operands following *command*.

check Equivalent to **info**, except that nothing shall be printed if nothing is being edited, and a non-zero exit status shall be returned if anything is being edited. The intent is to have this included in an ``install'' entry in a makefile to ensure that everything is included into the SCCS file before a version is installed.

clean Remove everything from the current directory that can be recreated from SCCS files, but do not remove any files being edited. If the −**b** option is given, branches shall be ignored in the determination of whether they are being edited; this is dangerous if branches are kept in the same directory.

create Create an SCCS file, taking the initial contents from the file of the same name. Any options to *admin* are accepted. If the creation is successful, the original files shall be renamed by prefixing the basenames with a comma. These renamed files should be removed after it has been verified that the SCCS files have been created successfully.

delget Perform a *delta* on the named files and then *get* new versions. The new versions shall have ID keywords expanded and shall not be editable. Any −**m**, −**p**, −**r**, −**s**, and −**y** options shall be passed to *delta*, and any −**b**, −**c**, −**e**, −**i**, −**k**, −**l**, −**s**, and −**x** options shall be passed to *get*.

deledit Equivalent to **delget**, except that the *get* phase shall include the −**e** option. This option is useful for making a checkpoint of the current editing phase. The same options shall be passed to *delta* as described above, and all the options listed for *get* above except −**e** shall be passed to **edit**.

diffs Write a difference listing between the current version of the files checked out for editing and the versions in SCCS format. Any −**r**, −**c**, −**i**, −**x**, and −**t** options shall be passed to *get*; any −**l**, −**s**, −**e**, −**f**, −**h**, and −**b** options shall be passed to *diff*. A −**C** option shall be passed to *diff* as −**c**.

edit Equivalent to *get* −**e**.

fix Remove the named delta, but leave a copy of the delta with the changes that were in it. It is useful for fixing small compiler bugs, and so on. The application shall ensure that it is followed by a −**r** *SID* option. Since **fix** does not leave audit trails, it should be used carefully.

info Write a listing of all files being edited. If the −**b** option is given, branches (that is, SIDs with two or fewer components) shall be ignored. If a −**u** *user* option is given, then only files being edited by the named user shall be listed. A −**U** option shall be equivalent to −**u**<*current user*>.

print Write out verbose information about the named files, equivalent to *sccs prs*.

tell Write a <newline>-separated list of the files being edited to standard output. Takes the −**b**, −**u**, and −**U** options like **info** and **check**.

unedit This is the opposite of an **edit** or a *get* −**e**. It should be used with caution, since any changes made since the *get* are lost.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Many of the SCCS utilities take directory names as operands as well as specific filenames. The pseudo-utilities supported by *sccs* are not described as having this capability, but are not prohibited from doing so.

EXAMPLES

1. To get a file for editing, edit it and produce a new delta:

```
sccs get -e file.c
ex file.c
sccs delta file.c
```

2. To get a file from another directory:

```
sccs -p /usr/src/sccs/s. get cc.c
```

or:

```
sccs get /usr/src/sccs/s.cc.c
```

3. To make a delta of a large number of files in the current directory:

```
sccs delta *.c
```

4. To get a list of files being edited that are not on branches:

```
sccs info -b
```

5. To delta everything being edited by the current user:

```
sccs delta $(sccs tell -U)
```

6. In a makefile, to get source files from an SCCS file if it does not already exist:

```
SRCS = <list of source files>
$(SRCS):
    sccs get $(REL) $@
```

RATIONALE

sccs and its associated utilities are part of the XSI Development Utilities option within the XSI option.

SCCS is an abbreviation for Source Code Control System. It is a maintenance and enhancement tracking tool. When a file is put under SCCS, the source code control system maintains the file and, when changes are made, identifies and stores them in the file with the original source code and/or documentation. As other changes are made, they too are identified and retained in the file.

Retrieval of the original and any set of changes is possible. Any version of the file as it develops can be reconstructed for inspection or additional modification. History data can be stored with each version, documenting why the changes were made, who made them, and when they were made.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 6

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from ``otherwise, the home directory of a user of that name is examined'' to ``otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory is examined''.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

sed — stream editor

SYNOPSIS

```
sed [−n] script [file...]
sed [−n] −e script [−e script]... [−f script_file]... [file...]
sed [−n] [−e script]... −f script_file [−f script_file]... [file...]
```

DESCRIPTION

The *sed* utility is a stream editor that shall read one or more text files, make editing changes according to a script of editing commands, and write the results to standard output. The script shall be obtained from either the *script* operand string or a combination of the option-arguments from the **−e** *script* and **−f** *script_file* options.

OPTIONS

The *sed* utility shall conform to XBD Section 12.2 (on page 216), except that the order of presentation of the **−e** and **−f** options is significant.

The following options shall be supported:

−e *script* Add the editing commands specified by the *script* option-argument to the end of the script of editing commands.

−f *script_file* Add the editing commands in the file *script_file* to the end of the script of editing commands.

−n Suppress the default output (in which each line, after it is examined for editing, is written to standard output). Only lines explicitly selected for output are written.

If any **−e** or **−f** options are specified, the script of editing commands shall initially be empty. The commands specified by each **−e** or **−f** option shall be added to the script in the order specified. When each addition is made, if the previous addition (if any) was from a **−e** option, a <newline> shall be inserted before the new addition. The resulting script shall have the same properties as the *script* operand, described in the OPERANDS section.

OPERANDS

The following operands shall be supported:

file A pathname of a file whose contents are read and edited. If multiple *file* operands are specified, the named files shall be read in the order specified and the concatenation shall be edited. If no *file* operands are specified, the standard input shall be used.

script A string to be used as the script of editing commands. The application shall not present a *script* that violates the restrictions of a text file except that the final character need not be a <newline>.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'−'` and the implementation treats the `'−'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files shall be text files. The *script_file*s named by the **−f** option shall consist of editing commands.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sed*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The input files shall be written to standard output, with the editing commands specified in the script applied. If the **−n** option is specified, only those input lines selected by the script shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic and warning messages.

OUTPUT FILES

The output files shall be text files whose formats are dependent on the editing commands given.

EXTENDED DESCRIPTION

The *script* shall consist of editing commands of the following form:

```
[address[,address]]function
```

where *function* represents a single-character command verb from the list in Editing Commands in sed (on page 3218), followed by any applicable arguments.

The command can be preceded by <blank> characters and/or <semicolon> characters. The function can be preceded by <blank> characters. These optional characters shall have no effect.

In default operation, *sed* cyclically shall append a line of input, less its terminating <newline> character, into the pattern space. Reading from input shall be skipped if a <newline> was in the pattern space prior to a **D** command ending the previous cycle. The *sed* utility shall then apply in sequence all commands whose addresses select that pattern space, until a command starts the next cycle or quits. If no commands explicitly started a new cycle, then at the end of the script the pattern space shall be copied to standard output (except when **−n** is specified) and the pattern space shall be deleted. Whenever the pattern space is written to standard output or a named file, *sed* shall immediately follow it with a <newline>.

Some of the editing commands use a hold space to save all or part of the pattern space for

107930 subsequent retrieval. The pattern and hold spaces shall each be able to hold at least 8 192 bytes.

107931 **Addresses in sed**

107932 An address is either a decimal number that counts input lines cumulatively across files, a `'$'`
107933 character that addresses the last line of input, or a context address (which consists of a BRE, as
107934 described in Regular Expressions in sed, preceded and followed by a delimiter, usually a
107935 <slash>).

107936 An editing command with no addresses shall select every pattern space.

107937 An editing command with one address shall select each pattern space that matches the address.

107938 An editing command with two addresses shall select the inclusive range from the first pattern
107939 space that matches the first address through the next pattern space that matches the second. (If
107940 the second address is a number less than or equal to the line number first selected, only one line
107941 shall be selected.) Starting at the first line following the selected range, *sed* shall look again for
107942 the first address. Thereafter, the process shall be repeated. Omitting either or both of the address
107943 components in the following form produces undefined results:

107944 **[***address***[,***address***]]**

107945 **Regular Expressions in sed**

107946 The *sed* utility shall support the BREs described in XBD Section 9.3 (on page 183), with the
107947 following additions:

107948 In a context address, the construction `"\cBREc"`, where *c* is any character other than
107949 <backslash> or <newline>, shall be identical to `"/BRE/"`. If the character designated by *c*
107950 appears following a <backslash>, then it shall be considered to be that literal character,
107951 which shall not terminate the BRE. For example, in the context address `"\xabc\xdefx"`,
107952 the second *x* stands for itself, so that the BRE is `"abcxdef"`.

107953 The escape sequence `'\n'` shall match a <newline> embedded in the pattern space. A
107954 literal <newline> shall not be used in the BRE of a context address or in the substitute
107955 function.

107956 If an RE is empty (that is, no pattern is specified) *sed* shall behave as if the last RE used in
107957 the last command applied (either as an address or as part of a substitute command) was
107958 specified.

107959 **Editing Commands in sed**

107960 In the following list of editing commands, the maximum number of permissible addresses for
107961 each function is indicated by [*0addr*], [*1addr*], or [*2addr*], representing zero, one, or two
107962 addresses.

107963 The argument *text* shall consist of one or more lines. Each embedded <newline> in the text shall
107964 be preceded by a <backslash>. Other <backslash> characters in text shall be removed, and the
107965 following character shall be treated literally.

107966 The **r** and **w** command verbs, and the *w* flag to the **s** command, take an *rfile* (or *wfile*) parameter,
107967 separated from the command verb letter or flag by one or more <blank> characters;
107968 implementations may allow zero separation as an extension.

107969 The argument *rfile* or the argument *wfile* shall terminate the editing command. Each *wfile* shall be
107970 created before processing begins. Implementations shall support at least ten *wfile* arguments in
107971 the script; the actual number (greater than or equal to 10) that is supported by the

implementation is unspecified. The use of the *wfile* parameter shall cause that file to be initially created, if it does not exist, or shall replace the contents of an existing file.

The **b**, **r**, **s**, **t**, **w**, **y**, and **:** command verbs shall accept additional arguments. The following synopses indicate which arguments shall be separated from the command verbs by a single <space>.

The **a** and **r** commands schedule text for later output. The text specified for the **a** command, and the contents of the file specified for the **r** command, shall be written to standard output just before the next attempt to fetch a line of input when executing the **N** or **n** commands, or when reaching the end of the script. If written when reaching the end of the script, and the **−n** option was not specified, the text shall be written after copying the pattern space to standard output. The contents of the file specified for the **r** command shall be as of the time the output is written, not the time the **r** command is applied. The text shall be output in the order in which the **a** and **r** commands were applied to the input.

Editing commands other than **{...}**, **a**, **b**, **c**, **i**, **r**, **t**, **w**, **:**, and **#** can be followed by a <semicolon>, optional <blank> characters, and another editing command. However, when an **s** editing command is used with the *w* flag, following it with another command in this manner produces undefined results.

A function can be preceded by a `'!'` character, in which case the function shall be applied if the addresses do not select the pattern space. Zero or more <blank> characters shall be accepted before the `'!'` character. It is unspecified whether <blank> characters can follow the `'!'` character, and conforming applications shall not follow the `'!'` character with <blank> characters.

If a *label* argument (to a **b**, **t**, or **:** command) contains characters outside of the portable filename character set, or if a *label* is longer than 8 bytes, the behavior is unspecified. The implementation shall support *label* arguments recognized as unique up to at least 8 bytes; the actual length (greater than or equal to 8) supported by the implementation is unspecified. It is unspecified whether exceeding the maximum supported label length causes an error or a silent truncation.

[*2addr***]** **{***editing command*
editing command
...
}
: Execute a list of *sed* editing commands only when the pattern space is selected. The list of *sed* editing commands shall be surrounded by braces. The braces can be preceded or followed by <blank> characters. The <right-brace> shall be preceded by a <newline> or <semicolon> (before any optional <blank> characters preceding the <right-brace>).

  Each command in the list of commands shall be terminated by a <newline> character, or by a <semicolon> character if permitted when the command is used outside the braces. The editing commands can be preceded by <blank> characters, but shall not be followed by <blank> characters.

[*1addr***]a**
text
: Write text to standard output as described previously.

[*2addr***]b [***label***]**
: Branch to the **:** command verb bearing the *label* argument. If *label* is not specified, branch to the end of the script.

[*2addr***]c**
text
: Delete the pattern space. With a 0 or 1 address or at the end of a 2-address range, place *text* on the output and start the next cycle.

[*2addr***]d** Delete the pattern space and start the next cycle.

[*2addr***]D** If the pattern space contains no <newline>, delete the pattern space and start a normal new cycle as if the **d** command was issued. Otherwise, delete the initial segment of the pattern space through the first <newline>, and start the next cycle with the resultant pattern space and without reading any new input.

[*2addr***]g** Replace the contents of the pattern space by the contents of the hold space.

[*2addr***]G** Append to the pattern space a <newline> followed by the contents of the hold space.

[*2addr***]h** Replace the contents of the hold space with the contents of the pattern space.

[*2addr***]H** Append to the hold space a <newline> followed by the contents of the pattern space.

[*1addr***]i**
text Write *text* to standard output.

[*2addr***]l** (The letter ell.) Write the pattern space to standard output in a visually unambiguous form. The characters listed in XBD Table 5-1 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequence; the `'\n'` in that table is not applicable. Non-printable characters not in that table shall be written as one three-digit octal number (with a preceding <backslash>) for each byte in the character (most significant byte first).

Long lines shall be folded, with the point of folding indicated by writing a <backslash> followed by a <newline>; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a `'$'`.

[*2addr***]n** Write the pattern space to standard output if the default output has not been suppressed, and replace the pattern space with the next line of input, less its terminating <newline>.

If no next line of input is available, the **n** command verb shall branch to the end of the script and quit without starting a new cycle.

[*2addr***]N** Append the next line of input, less its terminating <newline>, to the pattern space, using an embedded <newline> to separate the appended material from the original material. Note that the current line number changes.

If no next line of input is available, the **N** command verb shall branch to the end of the script and quit without starting a new cycle or copying the pattern space to standard output.

[*2addr***]p** Write the pattern space to standard output.

[*2addr***]P** Write the pattern space, up to the first <newline>, to standard output.

[*1addr***]q** Branch to the end of the script and quit without starting a new cycle.

[*1addr***]r** *rfile* Copy the contents of *rfile* to standard output as described previously. If *rfile* does not exist or cannot be read, it shall be treated as if it were an empty file, causing no error condition.

[*2addr***]s/***BRE***/***replacement***/***flags***
**
Substitute the replacement string for instances of the BRE in the pattern space. Any character other than <backslash> or <newline> can be used instead of a <slash> to

delimit the BRE and the replacement. Within the BRE and the replacement, the BRE delimiter itself can be used as a literal character if it is preceded by a <backslash>.

The replacement string shall be scanned from beginning to end. An <ampersand> ('`&`') appearing in the replacement shall be replaced by the string matching the BRE. The special meaning of '`&`' in this context can be suppressed by preceding it by a <backslash>. The characters "`\`*n*", where *n* is a digit, shall be replaced by the text matched by the corresponding back-reference expression. If the corresponding back-reference expression does not match, then the characters "`\`*n*" shall be replaced by the empty string. The special meaning of "`\`*n*" where *n* is a digit in this context, can be suppressed by preceding it by a <backslash>. For each other <backslash> encountered, the following character shall lose its special meaning (if any).

A line can be split by substituting a <newline> into it. The application shall escape the <newline> in the replacement by preceding it by a <backslash>.

The meaning of an unescaped <backslash> immediately followed by any character other than '`&`', <backslash>, a digit, <newline>, or the delimiter character used for this command, is unspecified.

A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces. Any <backslash> used to alter the default meaning of a subsequent character shall be discarded from the BRE or the replacement before evaluating the BRE or using the replacement.

The value of *flags* shall be zero or more of:

n Substitute for the *n*th occurrence only of the BRE found within the pattern space.

g Globally substitute for all non-overlapping instances of the BRE rather than just the first one. If both **g** and *n* are specified, the results are unspecified.

p Write the pattern space to standard output if a replacement was made.

w *wfile* Write. Append the pattern space to *wfile* if a replacement was made. A conforming application shall precede the *wfile* argument with one or more <blank> characters. If the **w** flag is not the last flag value given in a concatenation of multiple flag values, the results are undefined.

[2*addr*]**t [**label**]**

Test. Branch to the **:** command verb bearing the *label* if any substitutions have been made since the most recent reading of an input line or execution of a **t**. If *label* is not specified, branch to the end of the script.

[2*addr*]**w** *wfile*

Append (write) the pattern space to *wfile*.

[2*addr*]**x** Exchange the contents of the pattern and hold spaces.

[2*addr*]**y/**string1**/**string2**/**

Replace all occurrences of characters in *string1* with the corresponding characters in *string2*. If a <backslash> followed by an '`n`' appear in *string1* or *string2*, the two

characters shall be handled as a single <newline>. If the number of characters in *string1* and *string2* are not equal, or if any of the characters in *string1* appear more than once, the results are undefined. Any character other than <backslash> or <newline> can be used instead of <slash> to delimit the strings. If the delimiter is not `'n'`, within *string1* and *string2*, the delimiter itself can be used as a literal character if it is preceded by a <backslash>. If a <backslash> character is immediately followed by a <backslash> character in *string1* or *string2*, the two <backslash> characters shall be counted as a single literal <backslash> character. The meaning of a <backslash> followed by any character that is not `'n'`, a <backslash>, or the delimiter character is undefined.

[*0addr***]:***label* Do nothing. This command bears a *label* to which the **b** and **t** commands branch.

[*1addr***]=** Write the following to standard output:

`"%d\n", <current line number>`

[*0addr***]** Ignore this empty command.

[*0addr***]#** Ignore the `'#'` and the remainder of the line (treat them as a comment), with the single exception that if the first two characters in the script are `"#n"`, the default output shall be suppressed; this shall be the equivalent of specifying −**n** on the command line.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Regular expressions match entire strings, not just individual lines, but a <newline> is matched by `'\n'` in a *sed* RE; a <newline> is not allowed by the general definition of regular expression in POSIX.1-2017. Also note that `'\n'` cannot be used to match a <newline> at the end of an arbitrary input line; <newline> characters appear in the pattern space as a result of the **N** editing command.

When using *sed* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

EXAMPLES

This *sed* script simulates the BSD *cat* −**s** command, squeezing excess empty lines from standard input.

```
sed −n '
# Write non−empty lines.
/./ {
    p
    d
    }
# Write a single empty line, then look for more empty lines.
```

```
/^$/    p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/    {
    N
    s/.//
    b Empty
    }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
    p
'
```

The following *sed* command is a much simpler method of squeezing empty lines, although it is not quite the same as *cat* **−s** since it removes any initial empty lines:

```
sed −n '/./,/^$/p'
```

RATIONALE

This volume of POSIX.1-2017 requires implementations to support at least ten distinct *wfile*s, matching historical practice on many implementations. Implementations are encouraged to support more, but conforming applications should not exceed this limit.

The exit status codes specified here are different from those in System V. System V returns 2 for garbled *sed* commands, but returns zero with its usage message or if the input file could not be opened. The standard developers considered this to be a bug.

The manner in which the **l** command writes non-printable characters was changed to avoid the historical backspace-overstrike method, and other requirements to achieve unambiguous output were added. See the RATIONALE for *ed* for details of the format chosen, which is the same as that chosen for *sed*.

This volume of POSIX.1-2017 requires implementations to provide pattern and hold spaces of at least 8 192 bytes, larger than the 4 000 bytes spaces used by some historical implementations, but less than the 20 480 bytes limit used in an early proposal. Implementations are encouraged to allocate dynamically larger pattern and hold spaces as needed.

The requirements for acceptance of <blank> and <space> characters in command lines has been made more explicit than in early proposals to describe clearly the historical practice and to remove confusion about the phrase ``protect initial blanks [*sic*] and tabs from the stripping that is done on every script line'' that appears in much of the historical documentation of the *sed* utility description of text. (Not all implementations are known to have stripped <blank> characters from text lines, although they all have allowed leading <blank> characters preceding the address on a command line.)

The treatment of `'#'` comments differs from the SVID which only allows a comment as the first line of the script, but matches BSD-derived implementations. The comment character is treated as a command, and it has the same properties in terms of being accepted with leading <blank> characters; the BSD implementation has historically supported this.

Early proposals required that a *script_file* have at least one non-comment line. Some historical implementations have behaved in unexpected ways if this were not the case. The standard developers considered that this was incorrect behavior and that application developers should not have to avoid this feature. A correct implementation of this volume of POSIX.1-2017 shall permit *script_file*s that consist only of comment lines.

Early proposals indicated that if −**e** and −**f** options were intermixed, all −**e** options were processed before any −**f** options. This has been changed to process them in the order presented because it matches historical practice and is more intuitive.

The treatment of the **p** flag to the **s** command differs between System V and BSD-based systems when the default output is suppressed. In the two examples:

```
echo a | sed    's/a/A/p'
echo a | sed −n 's/a/A/p'
```

this volume of POSIX.1-2017, BSD, System V documentation, and the SVID indicate that the first example should write two lines with **A**, whereas the second should write one. Some System V systems write the **A** only once in both examples because the **p** flag is ignored if the −**n** option is not specified.

This is a case of a diametrical difference between systems that could not be reconciled through the compromise of declaring the behavior to be unspecified. The SVID/BSD/System V documentation behavior was adopted for this volume of POSIX.1-2017 because:

> No known documentation for any historic system describes the interaction between the **p** flag and the −**n** option.
>
> The selected behavior is more correct as there is no technical justification for any interaction between the **p** flag and the −**n** option. A relationship between −**n** and the **p** flag might imply that they are only used together, but this ignores valid scripts that interrupt the cyclical nature of the processing through the use of the **D**, **d**, **q**, or branching commands. Such scripts rely on the **p** suffix to write the pattern space because they do not make use of the default output at the ``bottom'' of the script.
>
> Because the −**n** option makes the **p** flag unnecessary, any interaction would only be useful if *sed* scripts were written to run both with and without the −**n** option. This is believed to be unlikely. It is even more unlikely that programmers have coded the **p** flag expecting it to be unnecessary. Because the interaction was not documented, the likelihood of a programmer discovering the interaction and depending on it is further decreased.
>
> Finally, scripts that break under the specified behavior produce too much output instead of too little, which is easier to diagnose and correct.

The form of the substitute command that uses the **n** suffix was limited to the first 512 matches in an early proposal. This limit has been removed because there is no reason an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/a/A/2047** should be able to substitute the 2 047th occurrence of **a** on a line.

The **b**, **t**, and **:** commands are documented to ignore leading white space, but no mention is made of trailing white space. Historical implementations of *sed* assigned different locations to the labels `'x'` and `"x "`. This is not useful, and leads to subtle programming errors, but it is historical practice, and changing it could theoretically break working scripts. Implementors are encouraged to provide warning messages about labels that are never referenced by a **b** or **t** command, jumps to labels that do not exist, and label arguments that are subject to truncation.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

> Implementations are required to support at least ten *wfile* arguments in an editing command.

The EXTENDED DESCRIPTION is changed to align with the IEEE P1003.2b draft standard.

IEEE PASC Interpretation 1003.2 #190 is applied.

IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the meaning of the <backslash>-escape sequences in a replacement string for a BRE.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/28 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/29 is applied, making an editorial correction within the Editing Commands in *sed* section.

Issue 7

Austin Group Interpretations 1003.1-2001 #006, #036, and #092 are applied.

SD5-XCU-ERN-97 and SD5-XCU-ERN-123 are applied, updating the SYNOPSIS.

A second example is added.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0133 [262], XCU/TC1-2008/0134 [282,431], XCU/TC1-2008/0135 [269], and XCU/TC1-2008/0136 [282,431] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0166 [945], XCU/TC2-2008/0167 [944], XCU/TC2-2008/0168 [945], XCU/TC2-2008/0169 [944], XCU/TC2-2008/0170 [945], XCU/TC2-2008/0171 [533], XCU/TC2-2008/0172 [663], XCU/TC2-2008/0173 [945], and XCU/TC2-2008/0174 [944] are applied.

NAME

sh ‡'shell, the standard command language interpreter

SYNOPSIS

```
sh [−abCefhimnuvx] [−o option]... [+abCefhimnuvx] [+o option]...
    [command_file [argument...]]

sh −c [−abCefhimnuvx] [−o option]... [+abCefhimnuvx] [+o option]...
    command_string [command_name [argument...]]

sh −s [−abCefhimnuvx] [−o option]... [+abCefhimnuvx] [+o option]...
    [argument...]
```

DESCRIPTION

The *sh* utility is a command language interpreter that shall execute commands read from a command line string, the standard input, or a specified file. The application shall ensure that the commands to be executed are expressed in the language described in Chapter 2 (on page 2345).

Pathname expansion shall not fail due to the size of a file.

Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

OPTIONS

The *sh* utility shall conform to XBD Section 12.2 (on page 216), with an extension for support of a leading <plus-sign> ('+') as noted below.

The **−a**, **−b**, **−C**, **−e**, **−f**, **−m**, **−n**, **−o** *option*, **−u**, **−v**, and **−x** options are described as part of the *set* utility in Section 2.14 (on page 2384). The option letters derived from the *set* special built-in shall also be accepted with a leading <plus-sign> ('+') instead of a leading <hyphen-minus> (meaning the reverse case of the option as described in this volume of POSIX.1-2017).

The following additional options shall be supported:

−c Read commands from the *command_string* operand. Set the value of special parameter 0 (see Section 2.5.2, on page 2350) from the value of the *command_name* operand and the positional parameters ($1, $2, and so on) in sequence from the remaining *argument* operands. No commands shall be read from the standard input.

−i Specify that the shell is *interactive*; see below. An implementation may treat specifying the **−i** option as an error if the real user ID of the calling process does not equal the effective user ID or if the real group ID does not equal the effective group ID.

−s Read commands from the standard input.

If there are no operands and the **−c** option is not specified, the **−s** option shall be assumed.

If the **−i** option is present, or if there are no operands and the shell's standard input and standard error are attached to a terminal, the shell is considered to be *interactive*.

OPERANDS

The following operands shall be supported:

− A single <hyphen-minus> shall be treated as the first operand and then ignored. If both '−' and "−−" are given as arguments, or if other operands precede the single <hyphen-minus>, the results are undefined.

argument The positional parameters ($1, $2, and so on) shall be set to *arguments*, if any.

command_file The pathname of a file containing commands. If the pathname contains one or more <slash> characters, the implementation attempts to read that file; the file need not be executable. If the pathname does not contain a <slash> character:

> The implementation shall attempt to read that file from the current working directory; the file need not be executable.
>
> If the file is not in the current working directory, the implementation may perform a search for an executable file using the value of *PATH*, as described in Section 2.9.1.1 (on page 2367).

Special parameter 0 (see Section 2.5.2, on page 2350) shall be set to the value of *command_file*. If *sh* is called using a synopsis form that omits *command_file*, special parameter 0 shall be set to the value of the first argument passed to *sh* from its parent (for example, *argv*[0] for a C program), which is normally a pathname used to execute the *sh* utility.

command_name
A string assigned to special parameter 0 when executing the commands in *command_string*. If *command_name* is not specified, special parameter 0 shall be set to the value of the first argument passed to *sh* from its parent (for example, *argv*[0] for a C program), which is normally a pathname used to execute the *sh* utility.

command_string
A string that shall be interpreted by the shell as one or more commands, as if the string were the argument to the *system*( ) function defined in the System Interfaces volume of POSIX.1-2017. If the *command_string* operand is an empty string, *sh* shall exit with a zero exit status.

STDIN

The standard input shall be used only if one of the following is true:

> The **−s** option is specified.
>
> The **−c** option is not specified and no operands are specified.
>
> The script executes one or more commands that require input from standard input (such as a *read* command that does not redirect its input).

See the INPUT FILES section.

When the shell is using standard input and it invokes a command that also uses standard input, the shell shall ensure that the standard input file pointer points directly after the command it has read when the command begins execution. It shall not read ahead in such a manner that any characters intended to be read by the invoked command are consumed by the shell (whether interpreted by the shell or not) or that characters that are not read by the invoked command are not seen by the shell. When the command expecting to read standard input is started asynchronously by an interactive shell, it is unspecified whether characters are read by the command or interpreted by the shell.

If the standard input to *sh* is a FIFO or terminal device and is set to non-blocking reads, then *sh* shall enable blocking reads on standard input. This shall remain in effect when the command completes.

INPUT FILES

The input file shall be a text file, except that line lengths shall be unlimited. If the input file consists solely of zero or more blank lines and comments, *sh* shall exit with a zero exit status.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sh*:

UP *ENV* This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2, on page 2354) by the shell, and the resulting value shall be used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of *ENV* is not an absolute pathname, the results are unspecified. *ENV* shall be ignored if the real and effective user IDs or real and effective group IDs of the process are different.

UP *FCEDIT* This variable, when expanded by the shell, shall determine the default value for the **−e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be used as the editor.

UP *HISTFILE* Determine a pathname naming a command history file. If the *HISTFILE* variable is not set, the shell may attempt to access or create a file **.sh_history** in the directory referred to by the *HOME* environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history ``file'' in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when *fc* or *sh* first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the *ENV* variable, or implementation-defined system start-up files. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set *HISTFILE*; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file.

HISTSIZE Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE* after the history file has been initialized are effective.

UP *HOME* Determine the pathname of the user's home directory. The contents of *HOME* are used in tilde expansion as described in Section 2.6.1 (on page 2354).

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the behavior of range expressions, equivalence classes, and multi-character collating elements within pattern matching.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), which characters are defined as letters (character class **alpha**), and the behavior of character classes within pattern matching.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

UP *MAIL* Determine a pathname of the user's mailbox file for purposes of incoming mail notification. If this variable is set, the shell shall inform the user if the file named by the variable is created or if its modification time has changed. Informing the user shall be accomplished by writing a string of unspecified format to standard error prior to the writing of the next primary prompt string. Such check shall be performed only after the completion of the interval defined by the *MAILCHECK* variable after the last such check. The user shall be informed only if *MAIL* is set and *MAILPATH* is not set.

UP *MAILCHECK*
Establish a decimal integer value that specifies how often (in seconds) the shell shall check for the arrival of mail in the files specified by the *MAILPATH* or *MAIL* variables. The default value shall be 600 seconds. If set to zero, the shell shall check before issuing each primary prompt.

UP *MAILPATH* Provide a list of pathnames and optional messages separated by <colon> characters. If this variable is set, the shell shall inform the user if any of the files named by the variable are created or if any of their modification times change. (See the preceding entry for *MAIL* for descriptions of mail arrival and user informing.) Each pathname can be followed by `'%'` and a string that shall be subjected to parameter expansion and written to standard error when the modification time changes. If a `'%'` character in the pathname is preceded by a <backslash>, it shall be treated as a literal `'%'` in the pathname. The default message is unspecified.

The *MAILPATH* environment variable takes precedence over the *MAIL* variable.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Establish a string formatted as described in XBD Chapter 8 (on page 173), used to effect command interpretation; see Section 2.9.1.1 (on page 2367).

PWD This variable shall represent an absolute pathname of the current working directory. Assignments to this variable may be ignored.

ASYNCHRONOUS EVENTS

The *sh* utility shall take the standard action for all signals (see Section 1.4, on page 2336) with the following exceptions.

If the shell is interactive, SIGINT signals received during command line editing shall be handled as described in the EXTENDED DESCRIPTION, and SIGINT signals received at other times shall be caught but no action performed.

If the shell is interactive:

SIGQUIT and SIGTERM signals shall be ignored.

If the **−m** option is in effect, SIGTTIN, SIGTTOU, and SIGTSTP signals shall be ignored.

If the **−m** option is not in effect, it is unspecified whether SIGTTIN, SIGTTOU, and SIGTSTP signals are ignored, set to the default action, or caught. If they are caught, the shell shall, in the signal-catching function, set the signal to the default action and raise the signal (after taking any appropriate steps, such as restoring terminal settings).

The standard actions, and the actions described above for interactive shells, can be overridden by use of the *trap* special built-in utility (see *trap* (on page 2420) and Section 2.11, on page 2381).

STDOUT

See the STDERR section.

STDERR

Except as otherwise stated (by the descriptions of any invoked utilities or in interactive mode), standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

UP See Chapter 2. The functionality described in the rest of the EXTENDED DESCRIPTION section shall be provided on implementations that support the User Portability Utilities option (and the rest of this section is not further shaded for this option).

Command History List

When the *sh* utility is being used interactively, it shall maintain a list of commands previously entered from the terminal in the file named by the *HISTFILE* environment variable. The type, size, and internal format of this file are unspecified. Multiple *sh* processes can share access to the file for a user, if file access permissions allow this; see the description of the *HISTFILE* environment variable.

Command Line Editing

When *sh* is being used interactively from a terminal, the current command and the command history (see *fc*) can be edited using *vi*-mode command line editing. This mode uses commands, described below, similar to a subset of those described in the *vi* utility. Implementations may offer other command line editing modes corresponding to other editing utilities.

The command *set* **−o** *vi* shall enable *vi*-mode editing and place *sh* into *vi* insert mode (see Command Line Editing (vi-mode), on page 3231). This command also shall disable any other editing mode that the implementation may provide. The command *set* **+o** *vi* disables *vi*-mode editing.

Certain block-mode terminals may be unable to support shell command line editing. If a terminal is unable to provide either edit mode, it need not be possible to *set* **−o** *vi* when using the shell on this terminal.

In the following sections, the characters *erase*, *interrupt*, *kill*, and *end-of-file* are those set by the *stty* utility.

Command Line Editing (vi-mode)

In *vi* editing mode, there shall be a distinguished line, the edit line. All the editing operations which modify a line affect the edit line. The edit line is always the newest line in the command history buffer.

With *vi*-mode enabled, *sh* can be switched between insert mode and command mode.

When in insert mode, an entered character shall be inserted into the command line, except as noted in vi Line Editing Insert Mode. Upon entering *sh* and after termination of the previous command, *sh* shall be in insert mode.

Typing an escape character shall switch *sh* into command mode (see vi Line Editing Command Mode, on page 3232). In command mode, an entered character shall either invoke a defined operation, be used as part of a multi-character operation, or be treated as an error. A character that is not recognized as part of an editing command shall terminate any specific editing command and shall alert the terminal. If *sh* receives a SIGINT signal in command mode (whether generated by typing the *interrupt* character or by other means), it shall terminate command line editing on the current command line, reissue the prompt on the next line of the terminal, and reset the command history (see *fc*) so that the most recently executed command is the previous command (that is, the command that was being edited when it was interrupted is not re-entered into the history).

In the following sections, the phrase ``move the cursor to the beginning of the word'' shall mean ``move the cursor to the first character of the current word'' and the phrase ``move the cursor to the end of the word'' shall mean ``move the cursor to the last character of the current word''. The phrase ``beginning of the command line'' indicates the point between the end of the prompt string issued by the shell (or the beginning of the terminal line, if there is no prompt string) and the first character of the command text.

vi Line Editing Insert Mode

While in insert mode, any character typed shall be inserted in the current command line, unless it is from the following set.

<newline> Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see *fc*).

erase Delete the character previous to the current cursor position and move the current cursor position back one character. In insert mode, characters shall be erased from both the screen and the buffer when backspacing.

interrupt If *sh* receives a SIGINT signal in insert mode (whether generated by typing the *interrupt* character or by other means), it shall terminate command line editing with the same effects as described for interrupting command mode; see Command Line Editing (vi-mode).

kill Clear all the characters from the input line.

<control>-V Insert the next character input, even if the character is otherwise a special insert mode character.

<control>-W Delete the characters from the one preceding the cursor to the preceding word boundary. The word boundary in this case is the closer to the cursor of either the beginning of the line or a character that is in neither the **blank** nor **punct** character classification of the current locale.

end-of-file Interpreted as the end of input in *sh*. This interpretation shall occur only at the beginning of an input line. If *end-of-file* is entered other than at the beginning of the line, the results are unspecified.

<ESC> Place *sh* into command mode.

vi Line Editing Command Mode

In command mode for the command line editing feature, decimal digits not beginning with 0 that precede a command letter shall be remembered. Some commands use these decimal digits as a count number that affects the operation.

The term *motion command* represents one of the commands:

```
<space>  0  b  F  l  W  ^  $  ;  E  f  T  w  |  ,  B  e  h  t
```

If the current line is not the edit line, any command that modifies the current line shall cause the content of the current line to replace the content of the edit line, and the current line shall become the edit line. This replacement cannot be undone (see the **u** and **U** commands below). The modification requested shall then be performed to the edit line. When the current line is the edit line, the modification shall be done directly to the edit line.

Any command that is preceded by *count* shall take a count (the numeric value of any preceding decimal digits). Unless otherwise noted, this count shall cause the specified operation to repeat by the number of times specified by the count. Also unless otherwise noted, a *count* that is out of range is considered an error condition and shall alert the terminal, but neither the cursor position, nor the command line, shall change.

The terms *word* and *bigword* are used as defined in the *vi* description. The term *save buffer* corresponds to the term *unnamed buffer* in *vi*.

The following commands shall be recognized in command mode:

<newline> Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see *fc*).

<control>-L Redraw the current command line. Position the cursor at the same location on the redrawn line.

Insert the character `'#'` at the beginning of the current command line and treat the resulting edit line as a comment. This line shall be entered into the command history; see *fc*.

= Display the possible shell word expansions (see Section 2.6, on page 2353) of the bigword at the current command line position.

Note: This does not modify the content of the current line, and therefore does not cause the current line to become the edit line.

These expansions shall be displayed on subsequent terminal lines. If the bigword contains none of the characters `'?'`, `'*'`, or `'['`, an <asterisk> (`'*'`) shall be implicitly assumed at the end. If any directories are matched, these expansions shall have a `'/'` character appended. After the expansion, the line shall be redrawn, the cursor repositioned at the current cursor position, and *sh* shall be placed in command mode.

\ Perform pathname expansion (see Section 2.6.6, on page 2360) on the current bigword, up to the largest set of characters that can be matched uniquely. If the bigword contains none of the characters `'?'`, `'*'`, or `'['`, an <asterisk> (`'*'`) shall be implicitly assumed at the end. This maximal expansion then shall replace

the original bigword in the command line, and the cursor shall be placed after this expansion. If the resulting bigword completely and uniquely matches a directory, a `'/'` character shall be inserted directly after the bigword. If some other file is completely matched, a single <space> shall be inserted after the bigword. After this operation, *sh* shall be placed in insert mode.

***** Perform pathname expansion on the current bigword and insert all expansions into the command to replace the current bigword, with each expansion separated by a single <space>. If at the end of the line, the current cursor position shall be moved to the first column position following the expansions and *sh* shall be placed in insert mode. Otherwise, the current cursor position shall be the last column position of the first character after the expansions and *sh* shall be placed in insert mode. If the current bigword contains none of the characters `'?'`, `'*'`, or `'['`, before the operation, an <asterisk> (`'*'`) shall be implicitly assumed at the end.

@*letter* Insert the value of the alias named *_letter*. The symbol *letter* represents a single alphabetic character from the portable character set; implementations may support additional characters as an extension. If the alias *_letter* contains other editing commands, these commands shall be performed as part of the insertion. If no alias *_letter* is enabled, this command shall have no effect.

[*count***]~** Convert, if the current character is a lowercase letter, to the equivalent uppercase letter and *vice versa*, as prescribed by the current locale. The current cursor position then shall be advanced by one character. If the cursor was positioned on the last character of the line, the case conversion shall occur, but the cursor shall not advance. If the `'~'` command is preceded by a *count*, that number of characters shall be converted, and the cursor shall be advanced to the character position after the last character converted. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***].** Repeat the most recent non-motion command, even if it was executed on an earlier command line. If the previous command was preceded by a *count*, and no count is given on the `'.'` command, the count from the previous command shall be included as part of the repeated command. If the `'.'` command is preceded by a *count*, this shall override any *count* argument to the previous command. The *count* specified in the `'.'` command shall become the count for subsequent `'.'` commands issued without a count.

[*number***]v** Invoke the *vi* editor to edit the current command line in a temporary file. When the editor exits, the commands in the temporary file shall be executed and placed in the command history. If a *number* is included, it specifies the command number in the command history to be edited, rather than the current command line.

[*count***]l** (ell)
[*count***]**<space>
Move the current cursor position to the next character position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]h** Move the current cursor position to the *count*th (default 1) previous character position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the

number of characters before the cursor, this shall not be considered an error; the cursor shall move to the first character on the line.

[*count***]w** Move to the start of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]W** Move to the start of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]e** Move to the end of the current word. If at the end of a word, move to the end of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]E** Move to the end of the current bigword. If at the end of a bigword, move to the end of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]b** Move to the beginning of the current word. If at the beginning of a word, move to the beginning of the previous word. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of words preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line.

[*count***]B** Move to the beginning of the current bigword. If at the beginning of a bigword, move to the beginning of the previous bigword. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of bigwords preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line.

^ Move the current cursor position to the first character on the input line that is not a <blank>.

$ Move to the last character position on the current command line.

0 (Zero.) Move to the first character position on the current command line.

[*count***] |** Move to the *count*th character position on the current command line. If no number is specified, move to the first position. The first character position shall be numbered 1. If the count is larger than the number of characters on the line, this shall not be considered an error; the cursor shall be placed on the last character on the line.

[*count***]f***c* Move to the first occurrence of the character '*c*' that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character '*c*'

does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]F***c* Move to the first occurrence of the character `'c'` that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character `'c'` does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]t***c* Move to the character before the first occurrence of the character `'c'` that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character `'c'` does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]T***c* Move to the character after the first occurrence of the character `'c'` that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character `'c'` does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***];** Repeat the most recent **f**, **F**, **t**, or **T** command. Any number argument on that previous command shall be ignored. Errors are those described for the repeated command.

[*count***],** Repeat the most recent **f**, **F**, **t**, or **T** command. Any number argument on that previous command shall be ignored. However, reverse the direction of that command.

a Enter insert mode after the current cursor position. Characters that are entered shall be inserted before the next character.

A Enter insert mode after the end of the current command line.

i Enter insert mode at the current cursor position. Characters that are entered shall be inserted before the current character.

I Enter insert mode at the beginning of the current command line.

R Enter insert mode, replacing characters from the command line beginning at the current cursor position.

[*count***]c***motion*

Delete the characters between the current cursor position and the cursor position that would result from the specified motion command. Then enter insert mode before the first character following any deleted characters. If *count* is specified, it shall be applied to the motion command. A *count* shall be ignored for the following motion commands:

```
0     ^     $     c
```

If the motion command is the character `'c'`, the current command line shall be cleared and insert mode shall be entered. If the motion command would move the current cursor position toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the motion command would move the current cursor position toward the end of the command line, the character under the current cursor position shall be deleted. If the *count* is larger than the number of characters between the current cursor position and the end of

the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted and insert mode shall be entered. If the motion command is invalid, the terminal shall be alerted, the cursor shall not be moved, and no text shall be deleted.

C Delete from the current character to the end of the line and enter insert mode at the new end-of-line.

S Clear the entire edit line and enter insert mode.

[*count*]**r***c* Replace the current character with the character '*c*'. With a number *count*, replace the current and the following *count*−1 characters. After this command, the current cursor position shall be on the last character that was changed. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; all of the remaining characters shall be changed.

[*count*]_ Append a <space> after the current character position and then append the last bigword in the previous input line after the <space>. Then enter insert mode after the last character just appended. With a number *count*, append the *count*th bigword in the previous line.

[*count*]**x** Delete the character at the current cursor position and place the deleted characters in the save buffer. If the cursor was positioned on the last character of the line, the character shall be deleted and the cursor position shall be moved to the previous character (the new last character). If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; all the characters from the cursor to the end of the line shall be deleted.

[*count*]**X** Delete the character before the current cursor position and place the deleted characters in the save buffer. The character under the current cursor position shall not change. If the cursor was positioned on the first character of the line, the terminal shall be alerted, and the **X** command shall have no effect. If the line contained a single character, the **X** command shall have no effect. If the line contained no characters, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of characters before the cursor, this shall not be considered an error; all the characters from before the cursor to the beginning of the line shall be deleted.

[*count*]**d***motion*

Delete the characters between the current cursor position and the character position that would result from the motion command. A number *count* repeats the motion command *count* times. If the motion command would move toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the motion command is **d**, the entire current command line shall be cleared. If the *count* is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted. The deleted characters shall be placed in the save buffer.

D Delete all characters from the current cursor position to the end of the line. The deleted characters shall be placed in the save buffer.

108757 [*count*]**y***motion*

108758 Yank (that is, copy) the characters from the current cursor position to the position
108759 resulting from the motion command into the save buffer. A number *count* shall be
108760 applied to the motion command. If the motion command would move toward the
108761 beginning of the command line, the character under the current cursor position
108762 shall not be included in the set of yanked characters. If the motion command is **y**,
108763 the entire current command line shall be yanked into the save buffer. The current
108764 cursor position shall be unchanged. If the *count* is larger than the number of
108765 characters between the current cursor position and the end of the command line
108766 toward which the motion command would move the cursor, this shall not be
108767 considered an error; all of the remaining characters in the aforementioned range
108768 shall be yanked.

108769 **Y** Yank the characters from the current cursor position to the end of the line into the
108770 save buffer. The current character position shall be unchanged.

108771 [*count*]**p** Put a copy of the current contents of the save buffer after the current cursor
108772 position. The current cursor position shall be advanced to the last character put
108773 from the save buffer. A *count* shall indicate how many copies of the save buffer
108774 shall be put.

108775 [*count*]**P** Put a copy of the current contents of the save buffer before the current cursor
108776 position. The current cursor position shall be moved to the last character put from
108777 the save buffer. A *count* shall indicate how many copies of the save buffer shall be
108778 put.

108779 **u** Undo the last command that changed the edit line. This operation shall not undo
108780 the copy of any command line to the edit line.

108781 **U** Undo all changes made to the edit line. This operation shall not undo the copy of
108782 any command line to the edit line.

108783 [*count*]**k**
108784 [*count*]– Set the current command line to be the *count*th previous command line in the shell
108785 command history. If *count* is not specified, it shall default to 1. The cursor shall be
108786 positioned on the first character of the new command. If a **k** or – command would
108787 retreat past the maximum number of commands in effect for this shell (affected by
108788 the *HISTSIZE* environment variable), the terminal shall be alerted, and the
108789 command shall have no effect.

108790 [*count*]**j**
108791 [*count*]**+** Set the current command line to be the *count*th next command line in the shell
108792 command history. If *count* is not specified, it shall default to 1. The cursor shall be
108793 positioned on the first character of the new command. If a **j** or **+** command
108794 advances past the edit line, the current command line shall be restored to the edit
108795 line and the terminal shall be alerted.

108796 [*number*]**G** Set the current command line to be the oldest command line stored in the shell
108797 command history. With a number *number*, set the current command line to be the
108798 command line *number* in the history. If command line *number* does not exist, the
108799 terminal shall be alerted and the command line shall not be changed.

108800 /*pattern*<newline>

108801 Move backwards through the command history, searching for the specified
108802 pattern, beginning with the previous command line. Patterns use the pattern
108803 matching notation described in Section 2.13 (on page 2382), except that the '^'

character shall have special meaning when it appears as the first character of *pattern*. In this case, the `'^'` is discarded and the characters after the `'^'` shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal shall be alerted. If it is found in a previous line, the current command line shall be set to that line and the cursor shall be set to the first character of the new command line.

If *pattern* is empty, the last non-empty pattern provided to **/** or **?** shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.

?*pattern*<newline>

Move forwards through the command history, searching for the specified pattern, beginning with the next command line. Patterns use the pattern matching notation described in Section 2.13 (on page 2382), except that the `'^'` character shall have special meaning when it appears as the first character of *pattern*. In this case, the `'^'` is discarded and the characters after the `'^'` shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal shall be alerted. If it is found in a following line, the current command line shall be set to that line and the cursor shall be set to the fist character of the new command line.

If *pattern* is empty, the last non-empty pattern provided to **/** or **?** shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.

n Repeat the most recent **/** or **?** command. If there is no previous **/** or **?**, the terminal shall be alerted and the current command line shall remain unchanged.

N Repeat the most recent **/** or **?** command, reversing the direction of the search. If there is no previous **/** or **?**, the terminal shall be alerted and the current command line shall remain unchanged.

EXIT STATUS

The following exit values shall be returned:

0 The script to be executed consisted solely of zero or more blank lines or comments, or both.

1-125 A non-interactive shell detected an error other than *command_file* not found or executable, including but not limited to syntax, redirection, or variable assignment errors.

126 A specified *command_file* could not be executed due to an [ENOEXEC] error (see Section 2.9.1.1 (on page 2367), item 2).

127 A specified *command_file* could not be found by a non-interactive shell.

Otherwise, the shell shall return the exit status of the last command it invoked or attempted to invoke (see also the *exit* utility in Section 2.14, on page 2384).

CONSEQUENCES OF ERRORS

See Section 2.8.1 (on page 2363).

APPLICATION USAGE

Standard input and standard error are the files that determine whether a shell is interactive when **–i** is not specified. For example:

```
sh > file
```

and:

```
sh 2> file
```

create interactive and non-interactive shells, respectively. Although both accept terminal input, the results of error conditions are different, as described in Section 2.8.1 (on page 2363); in the second example a redirection error encountered by a special built-in utility aborts the shell.

A conforming application must protect its first operand, if it starts with a <plus-sign>, by preceding it with the `"--"` argument that denotes the end of the options.

Applications should note that the standard *PATH* to the shell cannot be assumed to be either **/bin/sh** or **/usr/bin/sh**, and should be determined by interrogation of the *PATH* returned by *getconf PATH*, ensuring that the returned pathname is an absolute pathname and not a shell built-in.

For example, to determine the location of the standard *sh* utility:

```
command –v sh
```

On some implementations this might return:

```
/usr/xpg4/bin/sh
```

Furthermore, on systems that support executable scripts (the `"#!"` construct), it is recommended that applications using executable scripts install them using *getconf PATH* to determine the shell pathname and update the `"#!"` script appropriately as it is being installed (for example, with *sed*). For example:

```
#
# Installation time script to install correct POSIX shell pathname
#
# Get list of paths to check
#
Sifs=$IFS
Sifs_set=${IFS+y}
IFS=:
set -- $(getconf PATH)
if [ "$Sifs_set" = y ]
then
    IFS=$Sifs
else
    unset IFS
fi
#
# Check each path for 'sh'
#
for i
do
    if [ –x "${i}"/sh ]
    then
        Pshell=${i}/sh
```

```
        fi
    done
    #
    # This is the list of scripts to update. They should be of the
    # form '${name}.source' and will be transformed to '${name}'.
    # Each script should begin:
    #
    # #!INSTALLSHELLPATH
    #
    scripts="a b c"
    #
    # Transform each script
    #
    for i in ${scripts}
    do
        sed -e "s|INSTALLSHELLPATH|${Pshell}|" < ${i}.source > ${i}
    done
```

EXAMPLES

1. Execute a shell command from a string:

   ```
   sh -c "cat myfile"
   ```

2. Execute a shell script from a file in the current directory:

   ```
   sh my_shell_cmds
   ```

RATIONALE

The *sh* utility and the *set* special built-in utility share a common set of options.

The name *IFS* was originally an abbreviation of ``Input Field Separators''; however, this name is misleading as the *IFS* characters are actually used as field terminators. One justification for ignoring the contents of *IFS* upon entry to the script, beyond security considerations, is to assist possible future shell compilers. Allowing *IFS* to be imported from the environment prevents many optimizations that might otherwise be performed via dataflow analysis of the script itself.

The text in the STDIN section about non-blocking reads concerns an instance of *sh* that has been invoked, probably by a C-language program, with standard input that has been opened using the O_NONBLOCK flag; see *open*( ) in the System Interfaces volume of POSIX.1-2017. If the shell did not reset this flag, it would immediately terminate because no input data would be available yet and that would be considered the same as end-of-file.

The options associated with a *restricted shell* (command name *rsh* and the **−r** option) were excluded because the standard developers considered that the implied level of security could not be achieved and they did not want to raise false expectations.

On systems that support set-user-ID scripts, a historical trapdoor has been to link a script to the name **−i**. When it is called by a sequence such as:

```
sh -
```

or by:

```
#! usr/bin/sh -
```

the historical systems have assumed that no option letters follow. Thus, this volume of POSIX.1-2017 allows the single <hyphen-minus> to mark the end of the options, in addition to the use of the regular `"--"` argument, because it was considered that the older practice was so

pervasive. An alternative approach is taken by the KornShell, where real and effective user/group IDs must match for an interactive shell; this behavior is specifically allowed by this volume of POSIX.1-2017.

Note: There are other problems with set-user-ID scripts that the two approaches described here do not resolve.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the user's settings of *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file, unless the *set* **−o** *nolog* option is set. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user gets a chance to influence its characteristics. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Therefore, it is implementation-defined whether changes made to *HISTFILE* after the history file has been initialized are effective.

The default messages for the various *MAIL*-related messages are unspecified because they vary across implementations. Typical messages are:

```
"you have mail\n"
```

or:

```
"you have new mail\n"
```

It is important that the descriptions of command line editing refer to the same shell as that in POSIX.1-2017 so that interactive users can also be application programmers without having to deal with programmatic differences in their two environments. It is also essential that the utility name *sh* be specified because this explicit utility name is too firmly rooted in historical practice of application programs for it to change.

Consideration was given to mandating a diagnostic message when attempting to set *vi*-mode on terminals that do not support command line editing. However, it is not historical practice for the shell to be cognizant of all terminal types and thus be able to detect inappropriate terminals in all cases. Implementations are encouraged to supply diagnostics in this case whenever possible, rather than leaving the user in a state where editing commands work incorrectly.

In early proposals, the KornShell-derived *emacs* mode of command line editing was included, even though the *emacs* editor itself was not. The community of *emacs* proponents was adamant that the full *emacs* editor not be standardized because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship strictly conforming versions lacking the extensibility required by the community. The author of the original *emacs* program also expressed his desire to omit the program. Furthermore, there were a number of historical systems that did not include *emacs*, or included it without supporting it, but there were very few that did not include and support *vi*. The shell *emacs* command line editing mode was finally omitted because it became apparent that the KornShell version and the editor being distributed with the GNU system had diverged in some respects. The author of *emacs* requested that the POSIX *emacs* mode either be deleted or have a significant number of unspecified conditions. Although the KornShell author agreed to consider changes to bring the shell into alignment, the standard developers decided to defer specification at that time. At the time, it was assumed that convergence on an acceptable definition would occur for a subsequent draft, but that has not happened, and there appears to be no impetus to do so. In any case, implementations are free to offer additional command line editing modes based on the exact models of editors their users are most comfortable with.

Early proposals had the following list entry in vi Line Editing Insert Mode (on page 3231):

\ If followed by the *erase* or *kill* character, that character shall be inserted into the input line. Otherwise, the <backslash> itself shall be inserted into the input line.

However, this is not actually a feature of *sh* command line editing insert mode, but one of some historical terminal line drivers. Some conforming implementations continue to do this when the *stty* **iexten** flag is set.

In interactive shells, SIGTERM is ignored so that `kill 0` does not kill the shell, and SIGINT is caught so that *wait* is interruptible. If the shell does not ignore SIGTTIN, SIGTTOU, and SIGTSTP signals when it is interactive and the **−m** option is not in effect, these signals suspend the shell if it is not a session leader. If it is a session leader, the signals are discarded if they would stop the process, as required by XSH Section 2.4.3 (on page 490) for orphaned process groups.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Text is added to the DESCRIPTION for the Large File Summit proposal.

Issue 6

The Open Group Corrigendum U029/2 is applied, correcting the second SYNOPSIS.

The Open Group Corrigendum U027/3 is applied, correcting a typographical error.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

The option letters derived from the *set* special built-in are also accepted with a leading <plus-sign> (`'+'`).

Large file extensions are added:

‡ Pathname expansion does not fail due to the size of a file.

‡ Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

In the ENVIRONMENT VARIABLES section, the text ``user's home directory'' is updated to ``directory referred to by the *HOME* environment variable''.

Descriptions for the *ENV* and *PWD* environment variables are included to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #098 is applied, changing the definition of *IFS*.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Changes to the *pwd* utility and *PWD* environment variable have been made to match the changes to the *getcwd*( ) function made for Austin Group Interpretation 1003.1-2001 #140.

Minor editorial changes are made to the User Portability Utilities option shading. No normative changes are implied.

Minor changes are made to the install script example in the APPLICATION USAGE section.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0137 [152], XCU/TC1-2008/0138 [347], XCU/TC1-2008/0139 [347], XCU/TC1-2008/0140 [347], XCU/TC1-2008/0141 [299], and XCU/TC1-2008/0142 [347] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0175 [584], XCU/TC2-2008/0176 [584], XCU/TC2-2008/0177 [718], XCU/TC2-2008/0178 [884], XCU/TC2-2008/0179 [809], XCU/TC2-2008/0180 [884], and XCU/TC2-2008/0181 [584] are applied.

NAME

sleep ‡'suspend execution for an interval

SYNOPSIS

```
sleep time
```

DESCRIPTION

The *sleep* utility shall suspend execution for at least the integral number of seconds specified by the *time* operand.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

time A non-negative decimal integer specifying the number of seconds for which to suspend execution.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sleep*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

If the *sleep* utility receives a SIGALRM signal, one of the following actions shall be taken:

1. Terminate normally with a zero exit status.
2. Effectively ignore the signal.
3. Provide the default behavior for signals described in the ASYNCHRONOUS EVENTS section of Section 1.4 (on page 2336). This could include terminating with a non-zero exit status.

The *sleep* utility shall take the standard action for all other signals.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The execution was successfully suspended for at least *time* seconds, or a SIGALRM signal was received. See the ASYNCHRONOUS EVENTS section.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The *sleep* utility can be used to execute a command after a certain amount of time, as in:

```
(sleep 105; command) &
```

or to execute a command every so often, as in:

```
while true
do
    command
    sleep 37
done
```

RATIONALE

The exit status is allowed to be zero when *sleep* is interrupted by the SIGALRM signal because most implementations of this utility rely on the arrival of that signal to notify them that the requested finishing time has been successfully attained. Such implementations thus do not distinguish this situation from the successful completion case. Other implementations are allowed to catch the signal and go back to sleep until the requested time expires or to provide the normal signal termination procedures.

As with all other utilities that take integral operands and do not specify subranges of allowed values, *sleep* is required by this volume of POSIX.1-2017 to deal with *time* requests of up to 2 147 483 647 seconds. This may mean that some implementations have to make multiple calls to the delay mechanism of the underlying operating system if its argument range is less than this.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

sort — sort, merge, or sequence check text files

SYNOPSIS

```
sort [−m] [−o output] [−bdfinru] [−t char] [−k keydef]... [file...]
sort [−c|−C] [−bdfinru] [−t char] [−k keydef] [file]
```

DESCRIPTION

The *sort* utility shall perform one of the following functions:

1. Sort lines of all the named files together and write the result to the specified output.
2. Merge lines of all the named (presorted) files together and write the result to the specified output.
3. Check that a single input file is correctly presorted.

Comparisons shall be based on one or more sort keys extracted from each line of input (or, if no sort keys are specified, the entire line up to, but not including, the terminating <newline>), and shall be performed using the collating sequence of the current locale. If this collating sequence does not have a total ordering of all characters (see XBD Section 7.3.2, on page 147), any lines of input that collate equally should be further compared byte-by-byte using the collating sequence for the POSIX locale.

OPTIONS

The *sort* utility shall conform to XBD Section 12.2 (on page 216), except for Guideline 9, and the **−k** *keydef* option should follow the **−b**, **−d**, **−f**, **−i**, **−n**, and **−r** options. In addition, `'+'` may be recognized as an option delimiter as well as `'−'`.

The following options shall be supported:

−c Check that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. Output shall not be sent to standard output. The exit code shall indicate whether or not disorder was detected or an error occurred. If disorder (or, with **−u**, a duplicate key) is detected, a warning message shall be sent to standard error indicating where the disorder or duplicate key was found.

−C Same as **−c**, except that a warning message shall not be sent to standard error if disorder or, with **−u**, a duplicate key is detected.

−m Merge only; the input file shall be assumed to be already sorted.

−o *output* Specify the name of an output file to be used instead of the standard output. This file can be the same as one of the input *file*s.

−u Unique: suppress all but one in each set of lines having equal keys. If used with the **−c** option, check that there are no lines with duplicate keys, in addition to checking that the input file is sorted.

The following options shall override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules shall be applied globally to all sort keys. When attached to a specific key (see **−k**), the specified ordering options shall override all global ordering options for that key.

−d Specify that only <blank> characters and alphanumeric characters, according to the current setting of *LC_CTYPE*, shall be significant in comparisons. The behavior is undefined for a sort key to which **−i** or **−n** also applies.

109164 **−f** Consider all lowercase characters that have uppercase equivalents, according to
109165 the current setting of *LC_CTYPE*, to be the uppercase equivalent for the purposes
109166 of comparison.

109167 **−i** Ignore all characters that are non-printable, according to the current setting of
109168 *LC_CTYPE*. The behavior is undefined for a sort key for which **−n** also applies.

109169 **−n** Restrict the sort key to an initial numeric string, consisting of optional <blank>
109170 characters, optional <hyphen-minus> character, and zero or more digits with an
109171 optional radix character and thousands separators (as defined in the current
109172 locale), which shall be sorted by arithmetic value. An empty digit string shall be
109173 treated as zero. Leading zeros and signs on zeros shall not affect ordering.

109174 **−r** Reverse the sense of comparisons.

109175 The treatment of field separators can be altered using the options:

109176 **−b** Ignore leading <blank> characters when determining the starting and ending
109177 positions of a restricted sort key. If the **−b** option is specified before the first **−k**
109178 option, it shall be applied to all **−k** options. Otherwise, the **−b** option can be
109179 attached independently to each **−k** *field_start* or *field_end* option-argument (see
109180 below).

109181 **−t** *char* Use *char* as the field separator character; *char* shall not be considered to be part of a
109182 field (although it can be included in a sort key). Each occurrence of *char* shall be
109183 significant (for example, <*char*><*char*> delimits an empty field). If **−t** is not
109184 specified, <blank> characters shall be used as default field separators; each
109185 maximal non-empty sequence of <blank> characters that follows a non-<blank>
109186 shall be a field separator.

109187 Sort keys can be specified using the options:

109188 **−k** *keydef* The *keydef* argument is a restricted sort key field definition. The format of this
109189 definition is:

109190 *field_start*`[`*type*`][,`*field_end*`[`*type*`]]`

109191 where *field_start* and *field_end* define a key field restricted to a portion of the line
109192 (see the EXTENDED DESCRIPTION section), and *type* is one or more modifiers
109193 from the list of characters `'b'`, `'d'`, `'f'`, `'i'`, `'n'`, `'r'`. The `'b'` modifier shall
109194 behave like the **−b** option, but shall apply only to the *field_start* or *field_end* to
109195 which it is attached. The other modifiers shall behave like the corresponding
109196 options, but shall apply only to the key field to which they are attached; they shall
109197 have this effect if specified with *field_start*, *field_end*, or both. If any modifier is
109198 attached to a *field_start* or to a *field_end*, no option shall apply to either.
109199 Implementations shall support at least nine occurrences of the **−k** option, which
109200 shall be significant in command line order. If no **−k** option is specified, a default
109201 sort key of the entire line shall be used.

109202 When there are multiple key fields, later keys shall be compared only after all
109203 earlier keys compare equal. Except when the **−u** option is specified, lines that
109204 otherwise compare equal shall be ordered as if none of the options **−d**, **−f**, **−i**, **−n**, or
109205 **−k** were present (but with **−r** still in effect, if it was specified) and with all bytes in
109206 the lines significant to the comparison. The order in which lines that still compare
109207 equal are written is unspecified.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be sorted, merged, or checked. If no *file* operands are specified, or if a *file* operand is `'-'`, the standard input shall be used. If *sort* encounters an error when opening or reading a *file* operand, it may exit without writing any output to standard output or processing later operands.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'-'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that the *sort* utility shall add a <newline> to the end of a file ending with an incomplete last line.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sort*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for ordering rules.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classification for the **−b**, **−d**, **−f**, **−i**, and **−n** options.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the locale for the definition of the radix character and thousands separator for the **−n** option.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Unless the **−o** or **−c** options are in effect, the standard output shall contain the sorted input.

STDERR

The standard error shall be used for diagnostic messages. When **−c** is specified, if disorder is detected (or if **−u** is also specified and a duplicate key is detected), a message shall be written to the standard error which identifies the input line at which disorder (or a duplicate key) was detected. A warning message about correcting an incomplete last line of an input file may be generated, but need not affect the final exit status.

OUTPUT FILES

If the −**o** option is in effect, the sorted input shall be written to the file *output*.

EXTENDED DESCRIPTION

The notation:

−k *field_start*[*type*][,*field_end*[*type*]]

shall define a key field that begins at *field_start* and ends at *field_end* inclusive, unless *field_start* falls beyond the end of the line or after *field_end*, in which case the key field is empty. A missing *field_end* shall mean the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option −**t**, any preceding field separator.

The *field_start* portion of the *keydef* option-argument shall have the form:

field_number[.*first_character*]

Fields and characters within fields shall be numbered starting with 1. The *field_number* and *first_character* pieces, interpreted as positive decimal integers, shall specify the first character to be used as part of a sort key. If *.first_character* is omitted, it shall refer to the first character of the field.

The *field_end* portion of the *keydef* option-argument shall have the form:

field_number[.*last_character*]

The *field_number* shall be as described above for *field_start*. The *last_character* piece, interpreted as a non-negative decimal integer, shall specify the last character to be used as part of the sort key. If *last_character* evaluates to zero or *.last_character* is omitted, it shall refer to the last character of the field specified by *field_number*.

If the −**b** option or **b** type modifier is in effect, characters within a field shall be counted from the first non-<blank> in the field. (This shall apply separately to *first_character* and *last_character*.)

EXIT STATUS

The following exit values shall be returned:

0 All input files were output successfully, or −**c** was specified and the input file was correctly sorted.

1 Under the −**c** option, the file was not ordered as specified, or if the −**c** and −**u** options were both specified, two input lines were found with equal keys.

>1 An error occurred.

CONSEQUENCES OF ERRORS

The default requirements shall apply, except that if *sort* encounters an error when opening or reading a *file* operand, it may exit without writing any output to standard output or processing later operands.

APPLICATION USAGE

The default value for **−t**, <blank>, has different properties from, for example, **−t**"<space>". If a line contains:

```
<space><space>foo
```

the following treatment would occur with default separation as opposed to specifically selecting a <space>:

Field	Default	−t "<space>"
1	<space><space>foo	*empty*
2	*empty*	*empty*
3	*empty*	foo

The leading field separator itself is included in a field when **−t** is not used. For example, this command returns an exit status of zero, meaning the input was already sorted:

```
sort −c −k 2 <<eof
y<tab>b
x<space>a
eof
```

(assuming that a <tab> precedes the <space> in the current collating sequence). The field separator is not included in a field when it is explicitly set via **−t**. This is historical practice and allows usage such as:

```
sort −t "|" −k 2n <<eof
Atlanta|425022|Georgia
Birmingham|284413|Alabama
Columbia|100385|South Carolina
eof
```

where the second field can be correctly sorted numerically without regard to the non-numeric field separator.

The wording in the OPTIONS section clarifies that the **−b**, **−d**, **−f**, **−i**, **−n**, and **−r** options have to come before the first sort key specified if they are intended to apply to all specified keys. The way it is described in this volume of POSIX.1-2017 matches historical practice, not historical documentation. The results are unspecified if these options are specified after a **−k** option.

The **−f** option might not work as expected in locales where there is not a one-to-one mapping between an uppercase and a lowercase letter.

When using *sort* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

If the collating sequence of the current locale does not have a total ordering of all characters, this can affect the behavior of *sort* in the following ways:

As *sort* **−u** suppresses lines with duplicate keys, it suppresses lines that collate equally but are not identical.

The output of *sort* (without **−u**) can contain identical lines that are not adjacent, if it does not implement the recommended further byte-by-byte comparison of lines that collate equally. This affects the use of *sort* with *comm* and *uniq*; see the APPLICATION USAGE for

109329 those utilities.

109330 **EXAMPLES**

109331 1. The following command sorts the contents of **infile** with the second field as the sort key:

109332 ```
sort −k 2,2 infile
```

109333 2. The following command sorts, in reverse order, the contents of **infile1** and **infile2**,
109334 placing the output in **outfile** and using the second character of the second field as the sort
109335 key (assuming that the first character of the second field is the field separator):

109336 ```
sort −r −o outfile −k 2.2,2.2 infile1 infile2
```

109337 3. The following command sorts the contents of **infile1** and **infile2** using the second
109338 non-<blank> of the second field as the sort key:

109339 ```
sort −k 2.2b,2.2b infile1 infile2
```

109340 4. The following command prints the System V password file (user database) sorted by the
109341 numeric user ID (the third <colon>-separated field):

109342 ```
sort −t : −k 3,3n /etc/passwd
```

109343 5. The following command prints the lines of the already sorted file **infile**, suppressing all
109344 but one occurrence of lines having the same third field:

109345 ```
sort −um −k 3.1,3.0 infile
```

109346 **RATIONALE**

109347 Examples in some historical documentation state that options −**um** with one input file keep the
109348 first in each set of lines with equal keys. This behavior was deemed to be an implementation
109349 artifact and was not standardized.

109350 The −**z** option was omitted; it is not standard practice on most systems and is inconsistent with
109351 using *sort* to sort several files individually and then merge them together. The text concerning −**z**
109352 in historical documentation appeared to require implementations to determine the proper buffer
109353 length during the sort phase of operation, but not during the merge.

109354 The −**y** option was omitted because of non-portability. The −**M** option, present in System V, was
109355 omitted because of non-portability in international usage.

109356 An undocumented −**T** option exists in some implementations. It is used to specify a directory for
109357 intermediate files. Implementations are encouraged to support the use of the *TMPDIR*
109358 environment variable instead of adding an option to support this functionality.

109359 The −**k** option was added to satisfy two objections. First, the zero-based counting used by *sort* is
109360 not consistent with other utility conventions. Second, it did not meet syntax guideline
109361 requirements.

109362 Historical documentation indicates that ``setting −**n** implies −**b**''. The description of −**n** already
109363 states that optional leading <blank>s are tolerated in doing the comparison. If −**b** is enabled,
109364 rather than implied, by −**n**, this has unusual side-effects. When a character offset is used in a
109365 column of numbers (for example, to sort modulo 100), that offset is measured relative to the
109366 most significant digit, not to the column. Based upon a recommendation from the author of the
109367 original *sort* utility, the −**b** implication has been omitted from this volume of POSIX.1-2017, and
109368 an application wishing to achieve the previously mentioned side-effects has to code the −**b** flag
109369 explicitly.

109370 Earlier versions of this standard allowed the −**o** option to appear after operands. Historical
109371 practice allowed all options to be interspersed with operands. This version of the standard

  
```

allows implementations to accept options after operands but conforming applications should not use this form.

Earlier versions of this standard also allowed the *–number* and *+number* options. These options are no longer specified by POSIX.1-2017 but may be present in some implementations.

Historical implementations produced a message on standard error when **–c** was specified and disorder was detected, and when **–c** and **–u** were specified and a duplicate key was detected. An earlier version of this standard contained wording that did not make it clear that this message was allowed and some implementations removed this message to be sure that they conformed to the standard's requirements. Confronted with this difference in behavior, interactive users that wanted to be sure that they got visual feedback instead of just exit code 1 could have used a command like:

```
sort –c file || echo disorder
```

whether or not the *sort* utility provided a message in this case. But, it was not easy for a user to find where the disorder or duplicate key occurred on implementations that do not produce a message, especially when some parts of the input line were not part of the key and when one or more of the **–b**, **–d**, **–f**, **–i**, **–n**, or –r options or *keydef* type modifiers were in use. POSIX.1-2017 requires a message to be produced in this case. POSIX.1-2017 also contains the **–C** option giving users the ability to choose either behavior.

When a disorder or duplicate is found when the **–c** option is specified, some implementations print a message containing the first line that is out of order or contains a duplicate key; others print a message specifying the line number of the offending line. This standard allows either type of message.

Implementations are encouraged to perform the recommended further byte-by-byte comparison of lines that collate equally, even though this may affect efficiency. The impact on efficiency can be mitigated by only performing the additional comparison if the current locale's collating sequence does not have a total ordering of all characters (if the implementation provides a way to query this) or by only performing the additional comparison if the locale name associated with the LC_COLLATE category has an `'@'` modifier in the name (since locales without an `'@'` modifier should have a total ordering of all characters — see XBD Section 7.3.2, on page 147). Note that if the implementation provides a *stable sort* option as an extension (usually **–s**), the additional comparison should not be performed when this option has been specified.

FUTURE DIRECTIONS

A future version of this standard may require that if the collating sequence of the current locale does not have a total ordering of all characters, any lines of input that collate equally when comparing them as whole lines are further compared byte-by-byte using the collating sequence for the POSIX locale.

CHANGE HISTORY

First released in Issue 2.

Issue 6

IEEE PASC Interpretation 1003.2 #174 is applied, updating the DESCRIPTION of comparisons.

IEEE PASC Interpretation 1003.2 #168 is applied.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply and noting that `'+'` may be recognized as an option delimiter.

Austin Group Interpretation 1003.1-2001 #120 is applied, clarifying the use of the **−c** option and introducing the **−C** option.

XCU-ERN-81 is applied, modifying the description of the **−i** option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0182 [963], XCU/TC2-2008/0183 [584], XCU/TC2-2008/0184 [510], XCU/TC2-2008/0185 [962], XCU/TC2-2008/0186 [663], and XCU/TC2-2008/0187 [963] are applied.

NAME

split ‡'split a file into pieces

SYNOPSIS

```
split [-l line_count] [-a suffix_length] [file [name]]
split -b n[k|m] [-a suffix_length] [file [name]]
```

DESCRIPTION

The *split* utility shall read an input file and write zero or more output files. The default size of each output file shall be 1 000 lines. The size of the output files can be modified by specification of the **-b** or **-l** options. Each output file shall be created with a unique suffix. The suffix shall consist of exactly *suffix_length* lowercase letters from the POSIX locale. The letters of the suffix shall be used as if they were a base-26 digit system, with the first suffix to be created consisting of all `'a'` characters, the second with a `'b'` replacing the last `'a'`, and so on, until a name of all `'z'` characters is created. By default, the names of the output files shall be `'x'`, followed by a two-character suffix from the character set as described above, starting with `"aa"`, `"ab"`, `"ac"`, and so on, and continuing until the suffix `"zz"`, for a maximum of 676 files.

If the number of files required exceeds the maximum allowed by the suffix length provided, such that the last allowable file would be larger than the requested size, the *split* utility shall fail after creating the last file with a valid suffix; *split* shall not delete the files it created with valid suffixes. If the file limit is not exceeded, the last file created shall contain the remainder of the input file, and may be smaller than the requested size. If the input is an empty file, no output file shall be created and this shall not be considered to be an error.

OPTIONS

The *split* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-a *suffix_length*
: Use *suffix_length* letters to form the suffix portion of the filenames of the split file. If **-a** is not specified, the default suffix length shall be two. If the sum of the *name* operand and the *suffix_length* option-argument would create a filename exceeding {NAME_MAX} bytes, an error shall result; *split* shall exit with a diagnostic message and no files shall be created.

-b *n*
: Split a file into pieces *n* bytes in size.

-b *n***k**
: Split a file into pieces *n**1 024 bytes in size.

-b *n***m**
: Split a file into pieces *n**1 048 576 bytes in size.

-l *line_count*
: Specify the number of lines in each resulting file piece. The *line_count* argument is an unsigned decimal integer. The default is 1 000. If the input does not end with a <newline>, the partial line shall be included in the last output file.

OPERANDS

The following operands shall be supported:

file
: The pathname of the ordinary file to be split. If no input file is given or *file* is `'-'`, the standard input shall be used.

name
: The prefix to be used for each of the files resulting from the split operation. If no *name* argument is given, `'x'` shall be used as the prefix of the output files. The combined length of the basename of *prefix* and *suffix_length* cannot exceed {NAME_MAX} bytes. See the OPTIONS section.

STDIN

See the INPUT FILES section.

INPUT FILES

Any file can be used as input.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *split*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

In the following examples **foo** is a text file that contains 5 000 lines.

1. Create five files, **xaa**, **xab**, **xac**, **xad**, and **xae**:

   ```
   split foo
   ```

2. Create five files, but the suffixed portion of the created files consists of three letters, **xaaa**, **xaab**, **xaac**, **xaad**, and **xaae**:

   ```
   split –a 3 foo
   ```

3. Create three files with four-letter suffixes and a supplied prefix, **bar_aaaa**, **bar_aaab**, and **bar_aaac**:

   ```
   split –a 4 –l 2000 foo bar_
   ```

4. Create as many files as are necessary to contain at most 20*1 024 bytes, each with the default prefix of **x** and a five-letter suffix:

   ```
   split –a 5 –b 20k foo
   ```

RATIONALE

The –**b** option was added to provide a mechanism for splitting files other than by lines. While most uses of the –**b** option are for transmitting files over networks, some believed it would have additional uses.

The –**a** option was added to overcome the limitation of being able to create only 676 files.

Consideration was given to deleting this utility, using the rationale that the functionality provided by this utility is available via the *csplit* utility (see *csplit*). Upon reconsideration of the purpose of the User Portability Utilities option, it was decided to retain both this utility and the *csplit* utility because users use both utilities and have historical expectations of their behavior. Furthermore, the splitting on byte boundaries in *split* cannot be duplicated with the historical *csplit*.

The text ``*split* shall not delete the files it created with valid suffixes'' would normally be assumed, but since the related utility, *csplit*, does delete files under some circumstances, the historical behavior of *split* is made explicit to avoid misinterpretation.

Earlier versions of this standard allowed a *–line_count* option. This form is no longer specified by POSIX.1-2017 but may be present in some implementations.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied.

The *split* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0188 [731] is applied.

NAME

strings ‡'find printable strings in files

SYNOPSIS

```
strings [–a] [–t format] [–n number] [file...]
```

DESCRIPTION

The *strings* utility shall look for printable strings in regular files and shall write those strings to standard output. A printable string is any sequence of four (by default) or more printable characters terminated by a <newline> or NUL character. Additional implementation-defined strings may be written; see *localedef*.

If the first argument is `'–'`, the results are unspecified.

OPTIONS

The *strings* utility shall conform to XBD Section 12.2 (on page 216), except for the unspecified usage of `'–'`.

The following options shall be supported:

–a Scan files in their entirety. If **–a** is not specified, it is implementation-defined what portion of each file is scanned for strings.

–n *number* Specify the minimum string length, where the *number* argument is a positive decimal integer. The default shall be 4.

–t *format* Write each string preceded by its byte offset from the start of the file. The format shall be dependent on the single character used as the *format* option-argument:

`d` The offset shall be written in decimal.

`o` The offset shall be written in octal.

`x` The offset shall be written in hexadecimal.

OPERANDS

The following operand shall be supported:

file A pathname of a regular file to be used as input. If no *file* operand is specified, the *strings* utility shall read from the standard input.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files named by the utility arguments or the standard input shall be regular files of any format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *strings*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and to identify printable strings.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Strings found shall be written to the standard output, one per line.

When the **−t** option is not specified, the format of the output shall be:

`"%s", <string>`

With the **−t o** option, the format of the output shall be:

`"%o %s", <byte offset>, <string>`

With the **−t x** option, the format of the output shall be:

`"%x %s", <byte offset>, <string>`

With the **−t d** option, the format of the output shall be:

`"%d %s", <byte offset>, <string>`

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

By default the data area (as opposed to the text, ``bss'', or header areas) of a binary executable file is scanned. Implementations document which areas are scanned.

Some historical implementations do not require NUL or <newline> terminators for strings to permit those languages that do not use NUL as a string terminator to have their strings written.

EXAMPLES

None.

RATIONALE

Apart from rationalizing the option syntax and slight difficulties with object and executable binary files, *strings* is specified to match historical practice closely. The **−a** and **−n** options were introduced to replace the non-conforming − and *−number* options. These options are no longer specified by POSIX.1-2017 but may be present in some implementations.

The **−o** option historically means different things on different implementations. Some use it to mean ``*offset* in decimal'', while others use it as ``*offset* in octal''. Instead of trying to decide which way would be least objectionable, the **−t** option was added. It was originally named **−O** to mean ``offset'', but was changed to **−t** to be consistent with *od*.

The ISO C standard function *isprint*( ) is restricted to a domain of **unsigned char**. This volume of POSIX.1-2017 requires implementations to write strings as defined by the current locale.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first argument is `'−'`.

The *strings* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

strip — remove unnecessary information from strippable files (**DEVELOPMENT**)

SYNOPSIS

SD
```
strip file...
```

DESCRIPTION

XSI A strippable file is defined as a relocatable, object, or executable file. On XSI-conformant systems, a strippable file can also be an archive of object or relocatable files.

The *strip* utility shall remove from strippable files named by the *file* operands any information the implementor deems unnecessary for execution of those files. The nature of that information is unspecified. The effect of *strip* on object and executable files shall be similar to the use of the XSI **−s** option to *c99* or *fort77*. The effect of *strip* on an archive of object files shall be similar to the use of the **−s** option to *c99* or *fort77* for each object file in the archive.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file A pathname referring to a strippable file.

STDIN

Not used.

INPUT FILES

The input files shall be in the form of strippable files successfully produced by any compiler XSI defined by this volume of POSIX.1-2017 or produced by creating or updating an archive of such files using the *ar* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *strip*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

109699 **STDERR**

109700 The standard error shall be used only for diagnostic messages.

109701 **OUTPUT FILES**

109702 The *strip* utility shall produce strippable files of unspecified format.

109703 **EXTENDED DESCRIPTION**

109704 None.

109705 **EXIT STATUS**

109706 The following exit values shall be returned:

109707 0 Successful completion.

109708 >0 An error occurred.

109709 **CONSEQUENCES OF ERRORS**

109710 Default.

109711 **APPLICATION USAGE**

109712 None.

109713 **EXAMPLES**

109714 None.

109715 **RATIONALE**

109716 Historically, this utility has been used to remove the symbol table from a strippable file. It was
109717 included since it is known that the amount of symbolic information can amount to several
109718 megabytes; the ability to remove it in a portable manner was deemed important, especially for
109719 smaller systems.

109720 The behavior of *strip* on object and executable files is said to be the same as the **−s** option to a
109721 compiler. While the end result is essentially the same, it is not required to be identical.

109722 XSI-conformant systems support use of *strip* on archive files containing object files or relocatable
109723 files.

109724 **FUTURE DIRECTIONS**

109725 None.

109726 **SEE ALSO**

109727 *ar*, *c99*, *fort77*

109728 XBD Chapter 8 (on page 173)

109729 **CHANGE HISTORY**

109730 First released in Issue 2.

109731 **Issue 6**

109732 This utility is marked as part of the Software Development Utilities option.

109733 **Issue 7**

109734 Austin Group Interpretation 1003.1-2001 #103 is applied.

NAME

stty ‡'set the options for a terminal

SYNOPSIS

```
stty [-a|-g]
stty operand...
```

DESCRIPTION

The *stty* utility shall set or report on terminal I/O characteristics for the device that is its standard input. Without options or operands specified, it shall report the settings of certain characteristics, usually those that differ from implementation-defined defaults. Otherwise, it shall modify the terminal state according to the specified operands. Detailed information about the modes listed in the first five groups below are described in XBD Chapter 11 (on page 199). Operands in the Combination Modes group (see Combination Modes, on page 3269) are implemented using operands in the previous groups. Some combinations of operands are mutually-exclusive on some terminal types; the results of using such combinations are unspecified.

Typical implementations of this utility require a communications line configured to use the **termios** interface defined in the System Interfaces volume of POSIX.1-2017. On systems where none of these lines are available, and on lines not currently configured to support the **termios** interface, some of the operands need not affect terminal characteristics.

OPTIONS

The *stty* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-a Write to standard output all the current settings for the terminal.

-g Write to standard output all the current settings in an unspecified form that can be used as arguments to another invocation of the *stty* utility on the same system. The form used shall not contain any characters that would require quoting to avoid word expansion by the shell; see Section 2.6 (on page 2353).

OPERANDS

The following operands shall be supported to set the terminal characteristics.

Control Modes

parenb (**-parenb**) Enable (disable) parity generation and detection. This shall have the effect of setting (not setting) PARENB in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

parodd (**-parodd**)
Select odd (even) parity. This shall have the effect of setting (not setting) PARODD in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

cs5 cs6 cs7 cs8 Select character size, if possible. This shall have the effect of setting CS5, CS6, CS7, and CS8, respectively, in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

number Set terminal baud rate to the number given, if possible. If the baud rate is set to zero, the modem control lines shall no longer be asserted. This shall have the effect of setting the input and output **termios** baud rate values as defined in XBD Chapter 11 (on page 199).

ispeed *number* Set terminal input baud rate to the number given, if possible. If the input baud rate is set to zero, the input baud rate shall be specified by the value of the output baud rate. This shall have the effect of setting the input **termios** baud rate values as defined in XBD Chapter 11 (on page 199).

ospeed *number* Set terminal output baud rate to the number given, if possible. If the output baud rate is set to zero, the modem control lines shall no longer be asserted. This shall have the effect of setting the output **termios** baud rate values as defined in XBD Chapter 11 (on page 199).

hupcl (**–hupcl**) Stop asserting modem control lines (do not stop asserting modem control lines) on last close. This shall have the effect of setting (not setting) HUPCL in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

hup (**–hup**) Equivalent to **hupcl**(**–hupcl**).

cstopb (**–cstopb**) Use two (one) stop bits per character. This shall have the effect of setting (not setting) CSTOPB in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

cread (**–cread**) Enable (disable) the receiver. This shall have the effect of setting (not setting) CREAD in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

clocal (**–clocal**) Assume a line without (with) modem control. This shall have the effect of setting (not setting) CLOCAL in the **termios** *c_cflag* field, as defined in XBD Chapter 11 (on page 199).

It is unspecified whether *stty* shall report an error if an attempt to set a Control Mode fails.

Input Modes

ignbrk (**–ignbrk**) Ignore (do not ignore) break on input. This shall have the effect of setting (not setting) IGNBRK in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

brkint (**–brkint**) Signal (do not signal) INTR on break. This shall have the effect of setting (not setting) BRKINT in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

ignpar (**–ignpar**) Ignore (do not ignore) bytes with parity errors. This shall have the effect of setting (not setting) IGNPAR in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

parmrk (**–parmrk**)
Mark (do not mark) parity errors. This shall have the effect of setting (not setting) PARMRK in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

inpck (**–inpck**) Enable (disable) input parity checking. This shall have the effect of setting (not setting) INPCK in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

istrip (**–istrip**) Strip (do not strip) input characters to seven bits. This shall have the effect of setting (not setting) ISTRIP in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

inlcr (**–inlcr**) Map (do not map) NL to CR on input. This shall have the effect of setting (not setting) INLCR in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

igncr (–igncr) Ignore (do not ignore) CR on input. This shall have the effect of setting (not setting) IGNCR in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

icrnl (**–icrnl**) Map (do not map) CR to NL on input. This shall have the effect of setting (not setting) ICRNL in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

ixon (**–ixon**) Enable (disable) START/STOP output control. Output from the system is stopped when the system receives STOP and started when the system receives START. This shall have the effect of setting (not setting) IXON in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

ixany (**–ixany**) Allow any character to restart output. This shall have the effect of setting (not setting) IXANY in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

ixoff (**–ixoff**) Request that the system send (not send) STOP characters when the input queue is nearly full and START characters to resume data transmission. This shall have the effect of setting (not setting) IXOFF in the **termios** *c_iflag* field, as defined in XBD Chapter 11 (on page 199).

Output Modes

opost (**–opost**) Post-process output (do not post-process output; ignore all other output modes). This shall have the effect of setting (not setting) OPOST in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **onlcr** (**–onlcr**) Map (do not map) NL to CR-NL on output. This shall have the effect of setting (not setting) ONLCR in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **ocrnl** (**–ocrnl**) Map (do not map) CR to NL on output. This shall have the effect of setting (not setting) OCRNL in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **onocr** (**–onocr**) Do not (do) output CR at column zero. This shall have the effect of setting (not setting) ONOCR in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **onlret** (**–onlret**) The terminal newline key performs (does not perform) the CR function. This shall have the effect of setting (not setting) ONLRET in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **ofill** (**–ofill**) Use fill characters (use timing) for delays. This shall have the effect of setting (not setting) OFILL in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **ofdel** (**–ofdel**) Fill characters are DELs (NULs). This shall have the effect of setting (not setting) OFDEL in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **cr0 cr1 cr2 cr3** Select the style of delay for CRs. This shall have the effect of setting CRDLY to CR0, CR1, CR2, or CR3, respectively, in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **nl0 nl1** Select the style of delay for NL. This shall have the effect of setting NLDLY to NL0 or NL1, respectively, in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **tab0 tab1 tab2 tab3**
Select the style of delay for horizontal tabs. This shall have the effect of setting TABDLY to TAB0, TAB1, TAB2, or TAB3, respectively, in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199). Note that TAB3 has the effect of expanding <tab> characters to <space> characters.

XSI **tabs** (**–tabs**) Synonym for **tab0** (**tab3**).

XSI **bs0 bs1** Select the style of delay for <backspace> characters. This shall have the effect of setting BSDLY to BS0 or BS1, respectively, in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **ff0 ff1** Select the style of delay for <form-feed> characters. This shall have the effect of setting FFDLY to FF0 or FF1, respectively, in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

XSI **vt0 vt1** Select the style of delay for <vertical-tab> characters. This shall have the effect of setting VTDLY to VT0 or VT1, respectively, in the **termios** *c_oflag* field, as defined in XBD Chapter 11 (on page 199).

Local Modes

isig (**–isig**) Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SUSP. This shall have the effect of setting (not setting) ISIG in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

icanon (**–icanon**) Enable (disable) canonical input (ERASE and KILL processing). This shall have the effect of setting (not setting) ICANON in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

iexten (**–iexten**) Enable (disable) any implementation-defined special control characters not currently controlled by **icanon**, **isig**, **ixon**, or **ixoff**. This shall have the effect of setting (not setting) IEXTEN in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

echo (**–echo**) Echo back (do not echo back) every character typed. This shall have the effect of setting (not setting) ECHO in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

echoe (**–echoe**) The ERASE character visually erases (does not erase) the last character in the current line from the display, if possible. This shall have the effect of setting (not setting) ECHOE in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

echok (**–echok**) Echo (do not echo) NL after KILL character. This shall have the effect of setting (not setting) ECHOK in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

echonl (**–echonl**) Echo (do not echo) NL, even if **echo** is disabled. This shall have the effect of setting (not setting) ECHONL in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

noflsh (**–noflsh**) Disable (enable) flush after INTR, QUIT, SUSP. This shall have the effect of setting (not setting) NOFLSH in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

tostop (**–tostop**) Send SIGTTOU for background output. This shall have the effect of setting (not setting) TOSTOP in the **termios** *c_lflag* field, as defined in XBD Chapter 11 (on page 199).

Special Control Character Assignments

<control>-character string

Set *<control>-character* to *string*. If *<control>-character* is one of the character sequences in the first column of the following table, the corresponding XBD Chapter 11 (on page 199) control character from the second column shall be recognized. This has the effect of setting the corresponding element of the **termios** *c_cc* array (see XBD Chapter 13 (on page 219), **<termios.h>**).

Table 4-20 Control Character Names in *stty*

Control Character	c_cc Subscript	Description
eof	VEOF	EOF character
eol	VEOL	EOL character
erase	VERASE	ERASE character
intr	VINTR	INTR character
kill	VKILL	KILL character
quit	VQUIT	QUIT character
susp	VSUSP	SUSP character
start	VSTART	START character
stop	VSTOP	STOP character

If *string* is a single character, the control character shall be set to that character. If *string* is the two-character sequence `"^-"` or the string *undef*, the control character shall be set to _POSIX_VDISABLE , if it is in effect for the device; if _POSIX_VDISABLE is not in effect for the device, it shall be treated as an error. In the POSIX locale, if *string* is a two-character sequence beginning with <circumflex> (`'^'`), and the second character is one of those listed in the `"^c"` column of the following table, the control character shall be set to the corresponding character value in the Value column of the table.

Table 4-21 Circumflex Control Characters in *stty*

^c	Value	^c	Value	^c	Value
a, A	<SOH>	l, L	<FF>	w, W	<ETB>
b, B	<STX>	m, M	<CR>	x, X	<CAN>
c, C	<ETX>	n, N	<SO>	y, Y	<EM>
d, D	<EOT>	o, O	<SI>	z, Z	<SUB>
e, E	<ENQ>	p, P	<DLE>	[	<ESC>
f, F	<ACK>	q, Q	<DC1>	\	<FS>
g, G	<BEL>	r, R	<DC2>	]	<GS>
h, H	<BS>	s, S	<DC3>	^	<RS>
i, I	<HT>	t, T	<DC4>	_	<US>
j, J	<LF>	u, U	<NAK>	?	<DEL>
k, K	<VT>	v, V	<SYN>		

min *number*
Set the value of MIN to *number*. MIN is used in non-canonical mode input processing (**icanon**).

time *number*
Set the value of TIME to *number*. TIME is used in non-canonical mode input processing (**icanon**).

Combination Modes

saved settings
Set the current terminal characteristics to the saved settings produced by the **–g** option.

evenp or **parity**
Enable **parenb** and **cs7**; disable **parodd**.

oddp
Enable **parenb**, **cs7**, and **parodd**.

–parity, **–evenp**, or **–oddp**
Disable **parenb**, and set **cs8**.

XSI **raw** (**–raw** or **cooked**)
Enable (disable) raw input and output. Raw mode shall be equivalent to setting:

```
stty cs8 erase ^- kill ^- intr ^- \
    quit ^- eof ^- eol ^- -post -inpck
```

nl (**–nl**)
Disable (enable) **icrnl**. In addition, **–nl** unsets **inlcr** and **igncr**.

ek Reset ERASE and KILL characters back to system defaults.

sane
Reset all modes to some reasonable, unspecified, values.

STDIN

Although no input is read from standard input, standard input shall be used to get the current terminal I/O characteristics and to set new terminal I/O characteristics.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *stty*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE This variable determines the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and which characters are in the class **print**.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If operands are specified, no output shall be produced.

If the −**g** option is specified, *stty* shall write to standard output the current settings in a form that can be used as arguments to another instance of *stty* on the same system.

If the −**a** option is specified, all of the information as described in the OPERANDS section shall be written to standard output. Unless otherwise specified, this information shall be written as <space>-separated tokens in an unspecified format, on one or more lines, with an unspecified number of tokens per line. Additional information may be written.

If no options or operands are specified, an unspecified subset of the information written for the −**a** option shall be written.

If speed information is written as part of the default output, or if the −**a** option is specified and if the terminal input speed and output speed are the same, the speed information shall be written as follows:

`"speed %d baud;", <speed>`

Otherwise, speeds shall be written as:

`"ispeed %d baud; ospeed %d baud;", <ispeed>, <ospeed>`

In locales other than the POSIX locale, the word **baud** may be changed to something more appropriate in those locales.

If control characters are written as part of the default output, or if the −**a** option is specified, control characters shall be written as:

`"%s = %s;", <control-character name>, <value>`

where <*value*> is either the character, or some visual representation of the character if it is non-printable, or the string *undef* if the character is disabled.

110021 **STDERR**

110022 The standard error shall be used only for diagnostic messages.

110023 **OUTPUT FILES**

110024 None.

110025 **EXTENDED DESCRIPTION**

110026 None.

110027 **EXIT STATUS**

110028 The following exit values shall be returned:

110029 0 The terminal options were read or set successfully.

110030 >0 An error occurred.

110031 **CONSEQUENCES OF ERRORS**

110032 Default.

110033 **APPLICATION USAGE**

110034 The **−g** flag is designed to facilitate the saving and restoring of terminal state from the shell level.
110035 For example, a program may:

```
110036 saveterm="$(stty −g)"       # save terminal state
110037 stty (new settings)         # set new state
110038 ...                         # ...
110039 stty $saveterm               # restore terminal state
```

110040 Since the format is unspecified, the saved value is not portable across systems.

110041 Since the **−a** format is so loosely specified, scripts that save and restore terminal settings should
110042 use the **−g** option.

110043 **EXAMPLES**

110044 None.

110045 **RATIONALE**

110046 The original *stty* description was taken directly from System V and reflected the System V
110047 terminal driver **termio**. It has been modified to correspond to the terminal driver **termios**.

110048 Output modes are specified only for XSI-conformant systems. All implementations are expected
110049 to provide *stty* operands corresponding to all of the output modes they support.

110050 The *stty* utility is primarily used to tailor the user interface of the terminal, such as selecting the
110051 preferred ERASE and KILL characters. As an application programming utility, *stty* can be used
110052 within shell scripts to alter the terminal settings for the duration of the script.

110053 The **termios** section states that individual disabling of control characters is possible through the
110054 option _POSIX_VDISABLE. If enabled, two conventions currently exist for specifying this:
110055 System V uses `"^−"`, and BSD uses *undef*. Both are accepted by *stty* in this volume of
110056 POSIX.1-2017. The other BSD convention of using the letter `'u'` was rejected because it conflicts
110057 with the actual letter `'u'`, which is an acceptable value for a control character.

110058 Early proposals did not specify the mapping of `"^c"` to control characters because the control
110059 characters were not specified in the POSIX locale character set description file requirements. The
110060 control character set is now specified in XBD Chapter 3 (on page 33), so the historical mapping is
110061 specified. Note that although the mapping corresponds to control-character key assignments on
110062 many terminals that use the ISO/IEC 646:1991 standard (or ASCII) character encodings, the
110063 mapping specified here is to the control characters, not their keyboard encodings.

Since **termios** supports separate speeds for input and output, two new options were added to specify each distinctly.

Some historical implementations use standard input to get and set terminal characteristics; others use standard output. Since input from a login TTY is usually restricted to the owner while output to a TTY is frequently open to anyone, using standard input provides fewer chances of accidentally (or maliciously) altering the terminal settings of other users. Using standard input also allows *stty* **–a** and *stty* **–g** output to be redirected for later use. Therefore, usage of standard input is required by this volume of POSIX.1-2017.

NAME

tabs ‡'set terminal tabs

SYNOPSIS

XSI `tabs [-n|-a|-a2|-c|-c2|-c3|-f|-p|-s|-u] [-T type]`

`tabs [-T type] n[[sep[+]n]...]`

DESCRIPTION

The *tabs* utility shall display a series of characters that first clears the hardware terminal tab settings and then initializes the tab stops at the specified positions and optionally adjusts the margin.

The phrase ``tab-stop position *N*'' shall be taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line. The maximum number of tab stops allowed is terminal-dependent.

It need not be possible to implement *tabs* on certain terminals. If the terminal type obtained from the *TERM* environment variable or **−T** option represents such a terminal, an appropriate diagnostic message shall be written to standard error and *tabs* shall exit with a status greater than zero.

OPTIONS

XSI The *tabs* utility shall conform to XBD Section 12.2 (on page 216), except for various extensions: the options **−a2**, **−c2**, and **−c3** are multi-character.

The following options shall be supported:

−n Specify repetitive tab stops separated by a uniform number of column positions, *n*, where *n* is a single-digit decimal number. The default usage of *tabs* with no arguments shall be equivalent to *tabs* −8. When **−0** is used, the tab stops shall be cleared and no new ones set.

XSI **−a** 1,10,16,36,72
Assembler, applicable to some mainframes.

XSI **−a2** 1,10,16,40,72
Assembler, applicable to some mainframes.

XSI **−c** 1,8,12,16,20,55
COBOL, normal format.

XSI **−c2** 1,6,10,14,49
COBOL, compact format (columns 1 to 6 omitted).

XSI **−c3** 1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67
COBOL compact format (columns 1 to 6 omitted), with more tabs than **−c2**.

XSI **−f** 1,7,11,15,19,23
FORTRAN

XSI **−p** 1,5,9,13,17,21,25,29,33,37,41,45,49,53,57,61
PL/1

XSI **−s** 1,10,55
SNOBOL

XSI **−u** 1,12,20,44
Assembler, applicable to some mainframes.

110135 **−T** *type* Indicate the type of terminal. If this option is not supplied and the *TERM* variable
110136 is unset or null, an unspecified default terminal type shall be used. The setting of
110137 *type* shall take precedence over the value in *TERM*.

110138 **OPERANDS**

110139 The following operand shall be supported:

110140 *n*[[*sep*[+]*n*]...] A single command line argument that consists of one or more tab-stop values (*n*)
110141 separated by a separator character (*sep*) which is either a <comma> or a <blank>
110142 character. The application shall ensure that the tab-stop values are positive decimal
110143 integers in strictly ascending order. If any tab-stop value (except the first one) is
110144 preceded by a <plus-sign>, it is taken as an increment to be added to the previous
110145 value. For example, the tab lists 1,10,20,30 and `"1 10 +10 +10"` are considered
110146 to be identical.

110147 **STDIN**

110148 Not used.

110149 **INPUT FILES**

110150 None.

110151 **ENVIRONMENT VARIABLES**

110152 The following environment variables shall affect the execution of *tabs*:

110153 *LANG* Provide a default value for the internationalization variables that are unset or null.
110154 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
110155 variables used to determine the values of locale categories.)

110156 *LC_ALL* If set to a non-empty string value, override the values of all the other
110157 internationalization variables.

110158 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
110159 characters (for example, single-byte as opposed to multi-byte characters in
110160 arguments).

110161 *LC_MESSAGES*
110162 Determine the locale that should be used to affect the format and contents of
110163 diagnostic messages written to standard error.

110164 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

110165 *TERM* Determine the terminal type. If this variable is unset or null, and if the **−T** option is
110166 not specified, an unspecified default terminal type shall be used.

110167 **ASYNCHRONOUS EVENTS**

110168 Default.

110169 **STDOUT**

110170 If standard output is a terminal, the appropriate sequence to clear and set the tab stops may be
110171 written to standard output in an unspecified format. If standard output is not a terminal,
110172 undefined results occur.

110173 **STDERR**

110174 The standard error shall be used only for diagnostic messages.

110175 **OUTPUT FILES**

110176 None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility makes use of the terminal's hardware tabs and the *stty tabs* option.

This utility is not recommended for application use.

Some integrated display units might not have escape sequences to set tab stops, but may be set by internal system calls. On these terminals, *tabs* works if standard output is directed to the terminal; if output is directed to another file, however, *tabs* fails.

EXAMPLES

None.

RATIONALE

Consideration was given to having the *tput* utility handle all of the functions described in *tabs*. However, the separate *tabs* utility was retained because it seems more intuitive to use a command named *tabs* than *tput* with a new option. The *tput* utility does not support setting or clearing tabs, and no known historical version of *tabs* supports the capability of setting arbitrary tab stops.

The System V *tabs* interface is very complex; the version in this volume of POSIX.1-2017 has a reduced feature list, but many of the features omitted were restored as part of the XSI option even though the supported languages and coding styles are primarily historical.

There was considerable sentiment for specifying only a means of resetting the tabs back to a known state (presumably the ``standard'' of tabs every eight positions. The following features were omitted:

> Setting tab stops via the first line in a file, using *−−file*. Since even the SVID has no complete explanation of this feature, it is doubtful that it is in widespread use.

In an early proposal, a **−t** *tablist* option was added for consistency with *expand*; this was later removed when inconsistencies with the historical list of tabs were identified.

Consideration was given to adding a **−p** option that would output the current tab settings so that they could be saved and then later restored. This was not accepted because querying the tab stops of the terminal is not a capability in historical *terminfo* or *termcap* facilities and might not be supported on a wide range of terminals.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

The *tabs* utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The SYNOPSIS and OPERANDS sections are updated.

NAME

tail ‡'copy the last part of a file

SYNOPSIS

```
tail [-f] [-c number|-n number] [file]
```

DESCRIPTION

The *tail* utility shall copy its input file to the standard output beginning at a designated place.

Copying shall begin at the point in the file indicated by the **-c** *number* or **-n** *number* options. The option-argument *number* shall be counted in units of lines or bytes, according to the options **-n** and **-c**. Both line and byte counts start from 1.

Tails relative to the end of the file may be saved in an internal buffer, and thus may be limited in length. Such a buffer, if any, shall be no smaller than {LINE_MAX}*10 bytes.

OPTIONS

The *tail* utility shall conform to XBD Section 12.2 (on page 216), except that `'+'` may be recognized as an option delimiter as well as `'-'`.

The following options shall be supported:

-c *number* The application shall ensure that the *number* option-argument is a decimal integer, optionally including a sign. The sign shall affect the location in the file, measured in bytes, to begin the copying:

Sign	Copying Starts
+	Relative to the beginning of the file.
-	Relative to the end of the file.
none	Relative to the end of the file.

The application shall ensure that if the sign of the *number* option-argument is `'+'`, the *number* option-argument is a non-zero decimal integer.

The origin for counting shall be 1; that is, **-c** +1 represents the first byte of the file, **-c** -1 the last.

-f If the input file is a regular file or if the *file* operand specifies a FIFO, do not terminate after the last line of the input file has been copied, but read and copy further bytes from the input file when they become available. If no *file* operand is specified and standard input is a pipe or FIFO, the **-f** option shall be ignored. If the input file is not a FIFO, pipe, or regular file, it is unspecified whether or not the **-f** option shall be ignored.

-n *number* This option shall be equivalent to **-c** *number*, except the starting location in the file shall be measured in lines instead of bytes. The origin for counting shall be 1; that is, **-n** +1 represents the first line of the file, **-n** -1 the last.

If neither **-c** nor **-n** is specified, **-n** 10 shall be assumed.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operand is specified, the standard input shall be used.

110268 **STDIN**

110269 The standard input shall be used if no *file* operand is specified, and shall be used if the *file*
110270 operand is '−' and the implementation treats the '−' as meaning standard input. Otherwise,
110271 the standard input shall not be used. See the INPUT FILES section.

110272 **INPUT FILES**

110273 If the **−c** option is specified, the input file can contain arbitrary data; otherwise, the input file
110274 shall be a text file.

110275 **ENVIRONMENT VARIABLES**

110276 The following environment variables shall affect the execution of *tail*:

110277 *LANG* Provide a default value for the internationalization variables that are unset or null.
110278 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
110279 variables used to determine the values of locale categories.)

110280 *LC_ALL* If set to a non-empty string value, override the values of all the other
110281 internationalization variables.

110282 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
110283 characters (for example, single-byte as opposed to multi-byte characters in
110284 arguments and input files).

110285 *LC_MESSAGES*

110286 Determine the locale that should be used to affect the format and contents of
110287 diagnostic messages written to standard error.

110288 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

110289 **ASYNCHRONOUS EVENTS**

110290 Default.

110291 **STDOUT**

110292 The designated portion of the input file shall be written to standard output.

110293 **STDERR**

110294 The standard error shall be used only for diagnostic messages.

110295 **OUTPUT FILES**

110296 None.

110297 **EXTENDED DESCRIPTION**

110298 None.

110299 **EXIT STATUS**

110300 The following exit values shall be returned:

110301 0 Successful completion.

110302 >0 An error occurred.

110303 **CONSEQUENCES OF ERRORS**

110304 Default.

APPLICATION USAGE

The −**c** option should be used with caution when the input is a text file containing multi-byte characters; it may produce output that does not start on a character boundary.

Although the input file to *tail* can be any type, the results might not be what would be expected on some character special device files or on file types not described by the System Interfaces volume of POSIX.1-2017. Since this volume of POSIX.1-2017 does not specify the block size used when doing input, *tail* need not read all of the data from devices that only perform block transfers.

When using *tail* to process pathnames, and the −**c** option is not specified, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

EXAMPLES

The −**f** option can be used to monitor the growth of a file that is being written by some other process. For example, the command:

```
tail −f fred
```

prints the last ten lines of the file **fred**, followed by any lines that are appended to **fred** between the time *tail* is initiated and killed. As another example, the command:

```
tail −f −c 15 fred
```

prints the last 15 bytes of the file **fred**, followed by any bytes that are appended to **fred** between the time *tail* is initiated and killed.

RATIONALE

This version of *tail* was created to allow conformance to the Utility Syntax Guidelines. The historical −**b** option was omitted because of the general non-portability of block-sized units of text. The −**c** option historically meant ``characters'', but this volume of POSIX.1-2017 indicates that it means ``bytes''. This was selected to allow reasonable implementations when multi-byte characters are possible; it was not named −**b** to avoid confusion with the historical −**b**.

The origin of counting both lines and bytes is 1, matching all widespread historical implementations. Hence *tail* −**n** +0 is not conforming usage because it attempts to output line zero; but note that *tail* −**n** 0 does conform, and outputs nothing.

Earlier versions of this standard allowed the following forms in the SYNOPSIS:

```
tail −[number][b|c|l][f] [file]
tail +[number][b|c|l][f] [file]
```

These forms are no longer specified by POSIX.1-2017, but may be present in some implementations.

The restriction on the internal buffer is a compromise between the historical System V implementation of 4 096 bytes and the BSD 32 768 bytes.

The −**f** option has been implemented as a loop that sleeps for 1 second and copies any bytes that are available. This is sufficient, but if more efficient methods of determining when new data are available are developed, implementations are encouraged to use them.

Historical documentation indicates that *tail* ignores the −**f** option if the input file is a pipe (pipe and FIFO on systems that support FIFOs). On BSD-based systems, this has been true; on System V-based systems, this was true when input was taken from standard input, but it did not ignore

the **−f** flag if a FIFO was named as the *file* operand. Since the **−f** option is not useful on pipes and all historical implementations ignore **−f** if no *file* operand is specified and standard input is a pipe, this volume of POSIX.1-2017 requires this behavior. However, since the **−f** option is useful on a FIFO, this volume of POSIX.1-2017 also requires that if a FIFO is named, the **−f** option shall not be ignored. Earlier versions of this standard did not state any requirement for the case where no *file* operand is specified and standard input is a FIFO. The standard has been updated to reflect current practice which is to treat this case the same as a pipe on standard input. Although historical behavior does not ignore the **−f** option for other file types, this is unspecified so that implementations are allowed to ignore the **−f** option if it is known that the file cannot be extended.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent SYNOPSIS lines and associated text are removed.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that `'+'` may be recognized as an option delimiter in the OPTIONS section.

Austin Group Interpretation 1003.1-2001 #092 is applied.

Austin Group Interpretation 1003.1-2001 #100 is applied, adding the requirement on applications that if the sign of the option-argument *number* is `'+'`, the *number* option-argument is a non-zero decimal integer.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-114 is applied, updating the OPTIONS section (the **−f** option).

SD5-XCU-ERN-149 is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0190 [663] is applied.

NAME

talk ‡'talk to another user

SYNOPSIS

UP

```
talk address [terminal]
```

DESCRIPTION

The *talk* utility is a two-way, screen-oriented communication program.

When first invoked, *talk* shall send a message similar to:

```
Message from <unspecified string>
talk: connection requested by your_address
talk: respond with: talk your_address
```

to the specified *address*. At this point, the recipient of the message can reply by typing:

```
talk your_address
```

Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters shall be processed as follows:

Typing the <alert> character shall alert the recipient's terminal.

Typing <control>-L shall cause the sender's screen regions to be refreshed.

Typing the erase and kill characters shall affect the sender's terminal in the manner described by the **termios** interface in XBD Chapter 11 (on page 199).

Typing the interrupt or end-of-file characters shall terminate the local *talk* utility. Once the *talk* session has been terminated on one side, the other side of the *talk* session shall be notified that the *talk* session has been terminated and shall be able to do nothing except exit.

Typing characters from *LC_CTYPE* classifications **print** or **space** shall cause those characters to be sent to the recipient's terminal.

When and only when the *stty* **iexten** local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions shall be implementation-defined.

Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be sent to the recipient's terminal.

Permission to be a recipient of a *talk* message can be denied or granted by use of the *mesg* utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The *talk* utility shall fail when the user lacks appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for *talk*. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

address The recipient of the *talk* session. One form of *address* is the <*user name*>, as returned by the *who* utility. Other address formats and how they are handled are unspecified.

terminal If the recipient is logged in more than once, the *terminal* argument can be used to indicate the appropriate terminal name. If *terminal* is not specified, the *talk* message shall be displayed on one or more accessible terminals in use by the recipient. The format of *terminal* shall be the same as that returned by the *who* utility.

STDIN

Characters read from standard input shall be copied to the recipient's terminal in an unspecified manner. If standard input is not a terminal, talk shall write a diagnostic message and exit with a non-zero status.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *talk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient's locale does not use an *LC_CTYPE* equivalent to the sender's, the results are undefined.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TERM Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

When the *talk* utility receives a SIGINT signal, the utility shall terminate and exit with a zero status. It shall take the standard action for all other signals.

STDOUT

If standard output is a terminal, characters copied from the recipient's standard input may be written to standard output. Standard output also may be used for diagnostic messages. If standard output is not a terminal, *talk* shall exit with a non-zero status.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred or *talk* was invoked on a terminal incapable of supporting it.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Because the handling of non-printable, non-<space> characters is tied to the *stty* description of **iexten**, implementation extensions within the terminal driver can be accessed. For example, some implementations provide line editing functions with certain control character sequences.

EXAMPLES

None.

RATIONALE

The *write* utility was included in this volume of POSIX.1-2017 since it can be implemented on all terminal types. The *talk* utility, which cannot be implemented on certain terminals, was considered to be a ``better'' communications interface. Both of these programs are in widespread use on historical implementations. Therefore, both utilities have been specified.

All references to networking abilities (*talk*ing to a user on another system) were removed as being outside the scope of this volume of POSIX.1-2017.

Historical BSD and System V versions of *talk* terminate both of the conversations when either user breaks out of the session. This can lead to adverse consequences if a user unwittingly continues to enter text that is interpreted by the shell when the other terminates the session. Therefore, the version of *talk* specified by this volume of POSIX.1-2017 requires both users to terminate their end of the session explicitly.

Only messages sent to the terminal of the invoking user can be internationalized in any way:

> The original ``Message from <*unspecified string*> ...'' message sent to the terminal of the recipient cannot be internationalized because the environment of the recipient is as yet inaccessible to the *talk* utility. The environment of the invoking party is irrelevant.
>
> Subsequent communication between the two parties cannot be internationalized because the two parties may specify different languages in their environment (and non-portable characters cannot be mapped from one language to another).
>
> Neither party can be required to communicate in a language other than C and/or the one specified by their environment because unavailable terminal hardware support (for example, fonts) may be required.

The text in the STDOUT section reflects the usage of the verb ``display'' in this section; some *talk* implementations actually use standard output to write to the terminal, but this volume of POSIX.1-2017 does not require that to be the case.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use or accept the same format.

The handling of non-printable characters is partially implementation-defined because the details of mapping them to printable sequences is not needed by the user. Historical implementations, for security reasons, disallow the transmission of non-printable characters that may send commands to the other terminal.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Chapter 11 (on page 199)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

NAME

tee ‡’duplicate standard input

SYNOPSIS

```
tee [−ai] [file...]
```

DESCRIPTION

The *tee* utility shall copy standard input to standard output, making a copy in zero or more files. The *tee* utility shall not buffer output.

If the −**a** option is not specified, output files shall be written (see Section 1.1.1.4 (on page 2328).

OPTIONS

The *tee* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−**a** Append the output to the files.

−**i** Ignore the SIGINT signal.

OPERANDS

The following operands shall be supported:

file A pathname of an output file. If a *file* operand is '−', it shall refer to a file named −; implementations shall not treat it as meaning standard output. Processing of at least 13 *file* operands shall be supported.

STDIN

The standard input can be of any type.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tee*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default, except that if the −**i** option was specified, SIGINT shall be ignored.

STDOUT

The standard output shall be a copy of the standard input.

110557 **STDERR**

110558 The standard error shall be used only for diagnostic messages.

110559 **OUTPUT FILES**

110560 If any *file* operands are specified, the standard input shall be copied to each named file.

110561 **EXTENDED DESCRIPTION**

110562 None.

110563 **EXIT STATUS**

110564 The following exit values shall be returned:

110565 0 The standard input was successfully copied to all output files.

110566 >0 An error occurred.

110567 **CONSEQUENCES OF ERRORS**

110568 If a write to any successfully opened *file* operand fails, writes to other successfully opened *file*
110569 operands and standard output shall continue, but the exit status shall be non-zero. Otherwise,
110570 the default actions specified in Section 1.4 (on page 2336) apply.

110571 **APPLICATION USAGE**

110572 The *tee* utility is usually used in a pipeline, to make a copy of the output of some utility.

110573 The *file* operand is technically optional, but *tee* is no more useful than *cat* when none is specified.

110574 **EXAMPLES**

110575 Save an unsorted intermediate form of the data in a pipeline:

110576 ```
... | tee unsorted | sort > sorted
```

110577 **RATIONALE**

110578 The buffering requirement means that *tee* is not allowed to use ISO C standard fully buffered or
110579 line-buffered writes. It does not mean that *tee* has to do 1-byte reads followed by 1-byte writes.

110580 It should be noted that early versions of BSD ignore any invalid options and accept a single `'−'`
110581 as an alternative to **−i**. They also print a message if unable to open a file:

110582 `"tee: cannot access %s\n", <pathname>`

110583 Historical implementations ignore write errors. This is explicitly not permitted by this volume of
110584 POSIX.1-2017.

110585 Some historical implementations use O_APPEND when providing append mode; others use the
110586 *lseek*( ) function to seek to the end-of-file after opening the file without O_APPEND. This volume
110587 of POSIX.1-2017 requires functionality equivalent to using O_APPEND; see Section 1.1.1.4 (on
110588 page 2328).

110589 **FUTURE DIRECTIONS**

110590 None.

110591 **SEE ALSO**

NAME

test — evaluate expression

SYNOPSIS

```
test [expression]
[ [expression] ]
```

DESCRIPTION

The *test* utility shall evaluate the *expression* and indicate the result of the evaluation by its exit status. An exit status of zero indicates that the expression evaluated as true and an exit status of 1 indicates that the expression evaluated as false.

In the second form of the utility, where the utility name used is *[* rather than *test*, the application shall ensure that the closing square bracket is a separate argument. The *test* and *[* utilities may be implemented as a single linked utility which examines the basename of the zeroth command line argument to determine whether to behave as the *test* or *[* variant. Applications using the *exec*( ) family of functions to execute these utilities shall ensure that the argument passed in *arg0* or *argv*[0] is `'['` when executing the *[* utility and has a basename of `"test"` when executing the *test* utility.

OPTIONS

The *test* utility shall not recognize the `"--"` argument in the manner specified by Guideline 10 in XBD Section 12.2 (on page 216).

No options shall be supported.

OPERANDS

The application shall ensure that all operators and elements of primaries are presented as separate arguments to the *test* utility.

The following primaries can be used to construct *expression*:

−b *pathname* True if *pathname* resolves to an existing directory entry for a block special file. False if *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry for a file that is not a block special file.

−c *pathname* True if *pathname* resolves to an existing directory entry for a character special file. False if *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry for a file that is not a character special file.

−d *pathname* True if *pathname* resolves to an existing directory entry for a directory. False if *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry for a file that is not a directory.

−e *pathname* True if *pathname* resolves to an existing directory entry. False if *pathname* cannot be resolved.

−f *pathname* True if *pathname* resolves to an existing directory entry for a regular file. False if *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry for a file that is not a regular file.

−g *pathname* True if *pathname* resolves to an existing directory entry for a file that has its set-group-ID flag set. False if *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry for a file that does not have its set-group-ID flag set.

−h *pathname* True if *pathname* resolves to an existing directory entry for a symbolic link. False if *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry for a file that is not a symbolic link. If the final component of *pathname* is a symbolic link, that symbolic link is not followed.

110647 **−L** *pathname* True if *pathname* resolves to an existing directory entry for a symbolic link. False if
110648 *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry
110649 for a file that is not a symbolic link. If the final component of *pathname* is a
110650 symbolic link, that symbolic link is not followed.

110651 **−n** *string* True if the length of *string* is non-zero; otherwise, false.

110652 **−p** *pathname* True if *pathname* resolves to an existing directory entry for a FIFO. False if *pathname*
110653 cannot be resolved, or if *pathname* resolves to an existing directory entry for a file
110654 that is not a FIFO.

110655 **−r** *pathname* True if *pathname* resolves to an existing directory entry for a file for which
110656 permission to read from the file will be granted, as defined in Section 1.1.1.4 (on
110657 page 2328). False if *pathname* cannot be resolved, or if *pathname* resolves to an
110658 existing directory entry for a file for which permission to read from the file will not
110659 be granted.

110660 **−S** *pathname* True if *pathname* resolves to an existing directory entry for a socket. False if
110661 *pathname* cannot be resolved, or if *pathname* resolves to an existing directory entry
110662 for a file that is not a socket.

110663 **−s** *pathname* True if *pathname* resolves to an existing directory entry for a file that has a size
110664 greater than zero. False if *pathname* cannot be resolved, or if *pathname* resolves to an
110665 existing directory entry for a file that does not have a size greater than zero.

110666 **−t** *file_descriptor*
110667 True if file descriptor number *file_descriptor* is open and is associated with a
110668 terminal. False if *file_descriptor* is not a valid file descriptor number, or if file
110669 descriptor number *file_descriptor* is not open, or if it is open but is not associated
110670 with a terminal.

110671 **−u** *pathname* True if *pathname* resolves to an existing directory entry for a file that has its set-
110672 user-ID flag set. False if *pathname* cannot be resolved, or if *pathname* resolves to an
110673 existing directory entry for a file that does not have its set-user-ID flag set.

110674 **−w** *pathname* True if *pathname* resolves to an existing directory entry for a file for which
110675 permission to write to the file will be granted, as defined in Section 1.1.1.4 (on page
110676 2328). False if *pathname* cannot be resolved, or if *pathname* resolves to an existing
110677 directory entry for a file for which permission to write to the file will not be
110678 granted.

110679 **−x** *pathname* True if *pathname* resolves to an existing directory entry for a file for which
110680 permission to execute the file (or search it, if it is a directory) will be granted, as
110681 defined in Section 1.1.1.4 (on page 2328). False if *pathname* cannot be resolved, or if
110682 *pathname* resolves to an existing directory entry for a file for which permission to
110683 execute (or search) the file will not be granted.

110684 **−z** *string* True if the length of string *string* is zero; otherwise, false.

110685 *string* True if the string *string* is not the null string; otherwise, false.

110686 *s1* = *s2* True if the strings *s1* and *s2* are identical; otherwise, false.

110687 *s1* **!=** *s2* True if the strings *s1* and *s2* are not identical; otherwise, false.

110688 *n1* **−eq** *n2* True if the integers *n1* and *n2* are algebraically equal; otherwise, false.

110689 *n1* **−ne** *n2* True if the integers *n1* and *n2* are not algebraically equal; otherwise, false.

110690 *n1* **−gt** *n2* True if the integer *n1* is algebraically greater than the integer *n2*; otherwise, false.

110691 *n1* **−ge** *n2* True if the integer *n1* is algebraically greater than or equal to the integer *n2*;
110692 otherwise, false.

110693 *n1* **−lt** *n2* True if the integer *n1* is algebraically less than the integer *n2*; otherwise, false.

110694 *n1* **−le** *n2* True if the integer *n1* is algebraically less than or equal to the integer *n2*; otherwise,
110695 false.

110696 OB XSI *expression1* **−a** *expression2*
110697 True if both *expression1* and *expression2* are true; otherwise, false. The **−a** binary
110698 primary is left associative. It has a higher precedence than **−o**.

110699 OB XSI *expression1* **−o** *expression2*
110700 True if either *expression1* or *expression2* is true; otherwise, false. The **−o** binary
110701 primary is left associative.

110702 With the exception of the **−h** *pathname* and **−L** *pathname* primaries, if a *pathname* argument is a
110703 symbolic link, *test* shall evaluate the expression by resolving the symbolic link and using the file
110704 referenced by the link.

110705 These primaries can be combined with the following operators:

110706 **!** *expression* True if *expression* is false. False if *expression* is true.

110707 OB XSI **(** *expression* **)** True if *expression* is true. False if *expression* is false. The parentheses can be used to
110708 alter the normal precedence and associativity.

110709 The primaries with two elements of the form:

110710 `−primary_operator primary_operand`

110711 are known as *unary primaries*. The primaries with three elements in either of the two forms:

110712 `primary_operand −primary_operator primary_operand`

110713 `primary_operand primary_operator primary_operand`

110714 are known as *binary primaries*. Additional implementation-defined operators and
110715 *primary_operator*s may be provided by implementations. They shall be of the form *−operator*
110716 where the first character of *operator* is not a digit.

110717 The algorithm for determining the precedence of the operators and the return value that shall be
110718 generated is based on the number of arguments presented to *test*. (However, when using the
110719 `"[...]"` form, the <right-square-bracket> final argument shall not be counted in this
110720 algorithm.)

110721 In the following list, $1, $2, $3, and $4 represent the arguments presented to *test*:

110722 0 arguments: Exit false (1).

110723 1 argument: Exit true (0) if $1 is not null; otherwise, exit false.

110724 2 arguments: If $1 is `'!'`, exit true if $2 is null, false if $2 is not null.

110725 If $1 is a unary primary, exit true if the unary test is true, false if the
110726 unary test is false.

Otherwise, produce unspecified results.

3 arguments: If $2 is a binary primary, perform the binary test of $1 and $3.

If $1 is `'!'`, negate the two-argument test of $2 and $3.

OB XSI If $1 is `'('` and $3 is `')'`, perform the unary test of $2. On systems that do not support the XSI option, the results are unspecified if $1 is `'('` and $3 is `')'`.

Otherwise, produce unspecified results.

4 arguments: If $1 is `'!'`, negate the three-argument test of $2, $3, and $4.

OB XSI If $1 is `'('` and $4 is `')'`, perform the two-argument test of $2 and $3. On systems that do not support the XSI option, the results are unspecified if $1 is `'('` and $4 is `')'`.

Otherwise, the results are unspecified.

>4 arguments: The results are unspecified.

OB XSI On XSI-conformant systems, combinations of primaries and operators shall be evaluated using the precedence and associativity rules described previously. In addition, the string comparison binary primaries `'='` and `"!="` shall have a higher precedence than any unary primary.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *test*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

110766 **STDERR**

110767 The standard error shall be used only for diagnostic messages.

110768 **OUTPUT FILES**

110769 None.

110770 **EXTENDED DESCRIPTION**

110771 None.

110772 **EXIT STATUS**

110773 The following exit values shall be returned:

110774 0 *expression* evaluated to true.

110775 1 *expression* evaluated to false or *expression* was missing.

110776 >1 An error occurred.

110777 **CONSEQUENCES OF ERRORS**

110778 Default.

110779 **APPLICATION USAGE**

110780 The XSI extensions specifying the **−a** and **−o** binary primaries and the `'('` and `')'` operators
110781 have been marked obsolescent. (Many expressions using them are ambiguously defined by the
110782 grammar depending on the specific expressions being evaluated.) Scripts using these
110783 expressions should be converted to the forms given below. Even though many implementations
110784 will continue to support these obsolescent forms, scripts should be extremely careful when
110785 dealing with user-supplied input that could be confused with these and other primaries and
110786 operators. Unless the application developer knows all the cases that produce input to the script,
110787 invocations like:

110788 ```
test "$1" −a "$2"
```

110789 should be written as:

110790 ```
test "$1" && test "$2"
```

110791 to avoid problems if a user supplied values such as $1 set to `'!'` and $2 set to the null string.
110792 That is, in cases where maximal portability is of concern, replace:

110793 ```
test expr1 −a expr2
```

110794 with:

110795 ```
test expr1 && test expr2
```

110796 and replace:

110797 ```
test expr1 −o expr2
```

110798 with:

110799 ```
test expr1 || test expr2
```

110800 but note that, in *test*, **−a** has higher precedence than **−o** while `"&&"` and `"||"` have equal
110801 precedence in the shell.

110802 Parentheses or braces can be used in the shell command language to effect grouping.

110803 Parentheses must be escaped when using *sh*; for example:

110804 ```
test \(expr1 −a expr2 \) −o expr3
```

110805 This command is not always portable even on XSI-conformant systems depending on the

  
```

expressions specified by *expr*1, *expr*2, and *expr*3. The following form can be used instead:

```
( test expr1 && test expr2 ) || test expr3
```

The two commands:

```
test "$1"
test ! "$1"
```

could not be used reliably on some historical systems. Unexpected results would occur if such a *string* expression were used and $1 expanded to `'!'`, `'('`, or a known unary primary. Better constructs are:

```
test −n "$1"
test −z "$1"
```

respectively.

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"
```

One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

Note that the second form assumes that *expected string* could not be confused with any unary primary. If *expected string* starts with `'−'`, `'('`, `'!'`, or even `'='`, the first form should be used instead. Using the preceding rules without the XSI marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted in all cases.)

Because the string comparison binary primaries, `'='` and `"!="`, have a higher precedence than any unary primary in the greater than 4 argument case, unexpected results can occur if arguments are not properly prepared. For example, in:

```
test −d $1 −o −d $2
```

If $1 evaluates to a possible directory name of `'='`, the first three arguments are considered a string comparison, which shall cause a syntax error when the second **−d** is encountered. One of the following forms prevents this; the second is preferred:

```
test \( −d "$1" \) −o \( −d "$2" \)
test −d "$1" || test −d "$2"
```

Also in the greater than 4 argument case:

```
test "$1" = "bat" −a "$2" = "ball"
```

syntax errors occur if $1 evaluates to `'('` or `'!'`. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" −a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

Note that none of the following examples are permitted by the syntax described:

```
[−f file]
[−f file ]
[ −f file]
```

```
[ -f file
test -f file ]
```

In the first two cases, if a utility named *[-f* exists, that utility would be invoked, and not *test*. In the remaining cases, the brackets are mismatched, and the behavior is unspecified. However:

```
test ! ]
```

does have a defined meaning, and must exit with status 1. Similarly:

```
test ]
```

must exit with status 0.

EXAMPLES

1. Exit if there are not two or three arguments (two variations):

   ```
   if [ $# -ne 2 ] && [ $# -ne 3 ]; then exit 1; fi
   if [ $# -lt 2 ] || [ $# -gt 3 ]; then exit 1; fi
   ```

2. Perform a *mkdir* if a directory does not exist:

   ```
   test ! -d tempdir && mkdir tempdir
   ```

3. Wait for a file to become non-readable:

   ```
   while test -r thefile
   do
       sleep 30
   done
   echo '"thefile" is no longer readable'
   ```

4. Perform a command if the argument is one of three strings (two variations):

   ```
   if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
   then
       command
   fi
   ```

   ```
   case "$1" in
       pear|grape|apple) command ;;
   esac
   ```

RATIONALE

The KornShell-derived conditional command (double bracket **[[ ]]**) was removed from the shell command language description in an early proposal. Objections were raised that the real problem is misuse of the *test* command (**[**), and putting it into the shell is the wrong way to fix the problem. Instead, proper documentation and a new shell reserved word (**!**) are sufficient.

Tests that require multiple *test* operations can be done at the shell level using individual invocations of the *test* command and shell logicals, rather than using the error-prone **-o** flag of *test*.

XSI-conformant systems support more than four arguments.

XSI-conformant systems support the combining of primaries with the following constructs:

expression1 **-a** *expression2*
: True if both *expression1* and *expression2* are true.

expression1 **−o** *expression2*
True if at least one of *expression1* and *expression2* are true.

(*expression* **)**
True if *expression* is true.

In evaluating these more complex combined expressions, the following precedence rules are used:

The unary primaries have higher precedence than the algebraic binary primaries.

The unary primaries have lower precedence than the string binary primaries.

The unary and binary primaries have higher precedence than the unary *string* primary.

The **!** operator has higher precedence than the **−a** operator, and the **−a** operator has higher precedence than the **−o** operator.

The **−a** and **−o** operators are left associative.

The parentheses can be used to alter the normal precedence and associativity.

The BSD and System V versions of **−f** are not the same. The BSD definition was:

−f *file* True if *file* exists and is not a directory.

The SVID version (true if the file exists and is a regular file) was chosen for this volume of POSIX.1-2017 because its use is consistent with the **−b**, **−c**, **−d**, and **−p** operands (*file* exists and is a specific file type).

The **−e** primary, possessing similar functionality to that provided by the C shell, was added because it provides the only way for a shell script to find out if a file exists without trying to open the file. Since implementations are allowed to add additional file types, a portable script cannot use:

```
test −b foo −o −c foo −o −d foo −o −f foo −o −p foo
```

to find out if **foo** is an existing file. On historical BSD systems, the existence of a file could be determined by:

```
test −f foo −o −d foo
```

but there was no easy way to determine that an existing file was a regular file. An early proposal used the KornShell **−a** primary (with the same meaning), but this was changed to **−e** because there were concerns about the high probability of humans confusing the **−a** primary with the **−a** binary operator.

The following options were not included in this volume of POSIX.1-2017, although they are provided by some implementations. These operands should not be used by new implementations for other purposes:

−k *file* True if *file* exists and its sticky bit is set.

−C *file* True if *file* is a contiguous file.

−V *file* True if *file* is a version file.

The following option was not included because it was undocumented in most implementations, has been removed from some implementations (including System V), and the functionality is provided by the shell (see Section 2.6.2 (on page 2354).

110926 **−l** *string* The length of the string *string*.

110927 The **−b**, **−c**, **−g**, **−p**, **−u**, and **−x** operands are derived from the SVID; historical BSD does not
110928 provide them. The **−k** operand is derived from System V; historical BSD does not provide it.

110929 On historical BSD systems, *test* **−w** *directory* always returned false because *test* tried to open the
110930 directory for writing, which always fails.

110931 Some additional primaries newly invented or from the KornShell appeared in an early proposal
110932 as part of the conditional command ([[ ]]): *s1* **>** *s2*, *s1* **<** *s2*, *str* **=** *pattern*, *str* **!=** *pattern*, *f1* **−nt** *f2*, *f1*
110933 **−ot** *f2*, and *f1* **−ef** *f2*. They were not carried forward into the *test* utility when the conditional
110934 command was removed from the shell because they have not been included in the *test* utility
110935 built into historical implementations of the *sh* utility.

110936 The **−t** *file_descriptor* primary is shown with a mandatory argument because the grammar is
110937 ambiguous if it can be omitted. Historical implementations have allowed it to be omitted,
110938 providing a default of 1.

110939 It is noted that `'['` is not part of the portable filename character set; however, since it is required
110940 to be encoded by a single byte, and is part of the portable character set, the name of this utility
110941 forms a character string across all supported locales.

110947 **CHANGE HISTORY**

110948 First released in Issue 2.

110949 **Issue 5**

110950 The FUTURE DIRECTIONS section is added.

110951 **Issue 6**

110952 The **−h** operand is added for symbolic links, and access permission requirements are clarified for
110953 the **−r**, **−w**, and **−x** operands to align with the IEEE P1003.2b draft standard.

110954 The normative text is reworded to avoid use of the term ``must'' for application requirements.

110955 The **−L** and **−S** operands are added for symbolic links and sockets.

110956 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/38 is applied, adding XSI margin
110957 marking and shading to a line in the OPERANDS section referring to the use of parentheses as
110958 arguments to the *test* utility.

110959 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/30 is applied, rewording the existence
110960 primaries for the *test* utility.

110961 **Issue 7**

110962 Austin Group Interpretation 1003.1-2001 #107 is applied.

110963 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0143 [291] is applied.

110964 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0191 [898], XCU/TC2-2008/0192
110965 [730], and XCU/TC2-2008/0193 [898] are applied.

NAME

time ‡'time a simple command

SYNOPSIS

```
time [-p] utility [argument...]
```

DESCRIPTION

The *time* utility shall invoke the utility named by the *utility* operand with arguments supplied as the *argument* operands and write a message to standard error that lists timing statistics for the utility. The message shall include the following information:

The elapsed (real) time between invocation of *utility* and its termination.

The User CPU time, equivalent to the sum of the *tms_utime* and *tms_cutime* fields returned by the *times*( ) function defined in the System Interfaces volume of POSIX.1-2017 for the process in which *utility* is executed.

The System CPU time, equivalent to the sum of the *tms_stime* and *tms_cstime* fields returned by the *times*( ) function for the process in which *utility* is executed.

The precision of the timing shall be no less than the granularity defined for the size of the clock tick unit on the system, but the results shall be reported in terms of standard time units (for example, 0.02 seconds, 00:00:00.02, 1m33.75s, 365.21 seconds), not numbers of clock ticks.

When *time* is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command (see Section 2.9.4.1, on page 2371) in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities **a** and **c**, respectively:

```
time a | b | c     { time a; } | b | c
a | b | time c     a | b | (time c)
```

OPTIONS

The *time* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-p Write the timing output to standard error in the format shown in the STDERR section.

OPERANDS

The following operands shall be supported:

utility The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2384), the results are undefined.

argument Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *time*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

111009 *LC_ALL* If set to a non-empty string value, override the values of all the other
111010 internationalization variables.

111011 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
111012 characters (for example, single-byte as opposed to multi-byte characters in
111013 arguments).

111014 *LC_MESSAGES*
111015 Determine the locale that should be used to affect the format and contents of
111016 diagnostic and informative messages written to standard error.

111017 *LC_NUMERIC*
111018 Determine the locale for numeric formatting.

111019 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

111020 *PATH* Determine the search path that shall be used to locate the utility to be invoked; see
111021 XBD Chapter 8 (on page 173).

111022 **ASYNCHRONOUS EVENTS**
111023 Default.

111024 **STDOUT**
111025 Not used.

111026 **STDERR**
111027 If the *utility* utility is invoked, the standard error shall be used to write the timing statistics and
111028 may be used to write a diagnostic message if the utility terminates abnormally; otherwise, the
111029 standard error shall be used to write diagnostic messages and may also be used to write the
111030 timing statistics.

111031 If **−p** is specified, the following format shall be used for the timing statistics in the POSIX locale:

111032 `"real %f\nuser %f\nsys %f\n", <real seconds>, <user seconds>,`
111033 `<system seconds>`

111034 where each floating-point number shall be expressed in seconds. The precision used may be less
111035 than the default six digits of `%f`, but shall be sufficiently precise to accommodate the size of the
111036 clock tick on the system (for example, if there were 60 clock ticks per second, at least two digits
111037 shall follow the radix character). The number of digits following the radix character shall be no
111038 less than one, even if this always results in a trailing zero. The implementation may append
111039 white space and additional information following the format shown here. The implementation
111040 may also prepend a single empty line before the format shown here.

111041 **OUTPUT FILES**
111042 None.

111043 **EXTENDED DESCRIPTION**
111044 None.

111045 **EXIT STATUS**
111046 If the *utility* utility is invoked, the exit status of *time* shall be the exit status of *utility*; otherwise,
111047 the *time* utility shall exit with one of the following values:

111048 1-125 An error occurred in the *time* utility.

111049 126 The utility specified by *utility* was found but could not be invoked.

127 The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ``failure to find a utility'' from ``invoked utility exited with an error indication''. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ``normal error conditions'' and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

It is frequently desirable to apply *time* to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the *time* applies to everything in the file.

Alternatively, the following command can be used to apply *time* to a complex command:

```
time sh -c 'complex-command-line'
```

RATIONALE

When the *time* utility was originally proposed to be included in the ISO POSIX-2: 1993 standard, questions were raised about its suitability for inclusion on the grounds that it was not useful for conforming applications, specifically:

> The underlying CPU definitions from the System Interfaces volume of POSIX.1-2017 are vague, so the numeric output could not be compared accurately between systems or even between invocations.
>
> The creation of portable benchmark programs was outside the scope this volume of POSIX.1-2017.

However, *time* does fit in the scope of user portability. Human judgement can be applied to the analysis of the output, and it could be very useful in hands-on debugging of applications or in providing subjective measures of system performance. Hence it has been included in this volume of POSIX.1-2017.

The default output format has been left unspecified because historical implementations differ greatly in their style of depicting this numeric output. The **−p** option was invented to provide scripts with a common means of obtaining this information.

In the KornShell, *time* is a shell reserved word that can be used to time an entire pipeline, rather than just a simple command. The POSIX definition has been worded to allow this implementation. Consideration was given to invalidating this approach because of the historical model from the C shell and System V shell. However, since the System V *time* utility historically has not produced accurate results in pipeline timing (because the constituent processes are not all owned by the same parent process, as allowed by POSIX), it did not seem worthwhile to break historical KornShell usage.

The term *utility* is used, rather than *command*, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility* includes user application programs and shell scripts, not just the standard utilities.

FUTURE DIRECTIONS

None.

Chapter 2 (on page 2345), *sh*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

XSH *times*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Issue 7

The *time* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-115 is applied, updating the example in the DESCRIPTION.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0144 [266] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0194 [723] is applied.

NAME

touch ‡'change file access and modification times

SYNOPSIS

```
touch [−acm] [−r ref_file|−t time|−d date_time] file...
```

DESCRIPTION

The *touch* utility shall change the last data modification timestamps, the last data access timestamps, or both.

The time used can be specified by the −**t** *time* option-argument, the corresponding *time* fields of the file referenced by the −**r** *ref_file* option-argument, or the −**d** *date_time* option-argument, as specified in the following sections. If none of these are specified, *touch* shall use the current time.

For each *file* operand, *touch* shall perform actions equivalent to the following functions defined in the System Interfaces volume of POSIX.1-2017:

1. If *file* does not exist:
   a. The *creat*( ) function is called with the following arguments:
      ‡ The *file* operand is used as the *path* argument.
      ‡ The value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH is used as the *mode* argument.
   b. The *futimens*( ) function is called with the following arguments:
      ‡ The file descriptor opened in step 1a.
      ‡ The access time and the modification time, set as described in the OPTIONS section, are used as the first and second elements of the *times* array argument, respectively.
2. If *file* exists, the *utimensat*( ) function is called with the following arguments:
   a. The AT_FDCWD special value is used as the *fd* argument.
   b. The *file* operand is used as the *path* argument.
   c. The access time and the modification time, set as described in the OPTIONS section, are used as the first and second elements of the *times* array argument, respectively.
   d. The *flag* argument is set to zero.

OPTIONS

The *touch* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−**a** Change the access time of *file*. Do not change the modification time unless −**m** is also specified.

−**c** Do not create a specified *file* if it does not exist. Do not write any diagnostic messages concerning this condition.

−**d** *date_time* Use the specified *date_time* instead of the current time. The option-argument shall be a string of the form:

YYYY−*MM*−*DD*T*hh*:*mm*:*SS*[.*frac*][*tz*]

or:

111152 `YYYY-MM-DDThh:mm:SS[,frac][tz]`

111153 where:

111154 *YYYY* are at least four decimal digits giving the year.

111155 *MM*, *DD*, *hh*, *mm*, and *SS* are as with **−t** *time*.

111156 `T` is the time designator, and can be replaced by a single <space>.

111157 `[.frac]` and `[,frac]` are either empty, or a <period> (`'.'`) or a <comma>
111158 (`','`) respectively, followed by one or more decimal digits, specifying a
111159 fractional second.

111160 `[tz]` is either empty, signifying local time, or the letter `'Z'`, signifying UTC.
111161 If `[tz]` is empty, the resulting time shall be affected by the value of the *TZ*
111162 environment variable.

111163 If the resulting time precedes the Epoch, the behavior is implementation-defined. If
111164 the time cannot be represented as the file's timestamp, *touch* shall exit immediately
111165 with an error status.

111166 **−m** Change the modification time of *file*. Do not change the access time unless **−a** is
111167 also specified.

111168 **−r** *ref_file* Use the corresponding time of the file named by the pathname *ref_file* instead of
111169 the current time.

111170 **−t** *time* Use the specified *time* instead of the current time. The option-argument shall be a
111171 decimal number of the form:

111172 **[[***CC***]***YY***]***MMDDhhmm***[.***SS***]**

111173 where each two digits represents the following:

111174 *MM* The month of the year [01,12].

111175 *DD* The day of the month [01,31].

111176 *hh* The hour of the day [00,23].

111177 *mm* The minute of the hour [00,59].

111178 *CC* The first two digits of the year (the century).

111179 *YY* The second two digits of the year.

111180 *SS* The second of the minute [00,60].

111181 Both *CC* and *YY* shall be optional. If neither is given, the current year shall be
111182 assumed. If *YY* is specified, but *CC* is not, *CC* shall be derived as follows:

111183

If *YY* **is:**	*CC* **becomes:**
[69,99]	19
[00,68]	20

111184
111185

111186 **Note:** It is expected that in a future version of this standard the default century inferred
111187 from a 2-digit year will change. (This would apply to all commands accepting a
111188 2-digit year as input.)

111189 The resulting time shall be affected by the value of the *TZ* environment variable. If
111190 the resulting time value precedes the Epoch, the behavior is implementation-
111191 defined. If the time is out of range for the file's timestamp, *touch* shall exit

111192 immediately with an error status. The range of valid times past the Epoch is
111193 implementation-defined, but it shall extend to at least the time 0 hours, 0 minutes,
111194 0 seconds, January 1, 2038, Coordinated Universal Time. Some implementations
111195 may not be able to represent dates beyond January 18, 2038, because they use
111196 **signed int** as a time holder.

111197 The range for *SS* is [00,60] rather than [00,59] because of leap seconds. If *SS* is 60,
111198 and the resulting time, as affected by the *TZ* environment variable, does not refer
111199 to a leap second, the resulting time shall be one second after a time where *SS* is 59.
111200 If *SS* is not given a value, it is assumed to be zero.

111201 If neither the −**a** nor −**m** options were specified, *touch* shall behave as if both the −**a** and −**m**
111202 options were specified.

111203 **OPERANDS**

111204 The following operands shall be supported:

111205 *file* A pathname of a file whose times shall be modified.

111206 **STDIN**

111207 Not used.

111208 **INPUT FILES**

111209 None.

111210 **ENVIRONMENT VARIABLES**

111211 The following environment variables shall affect the execution of *touch*:

111212 *LANG* Provide a default value for the internationalization variables that are unset or null.
111213 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
111214 variables used to determine the values of locale categories.)

111215 *LC_ALL* If set to a non-empty string value, override the values of all the other
111216 internationalization variables.

111217 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
111218 characters (for example, single-byte as opposed to multi-byte characters in
111219 arguments).

111220 *LC_MESSAGES*
111221 Determine the locale that should be used to affect the format and contents of
111222 diagnostic messages written to standard error.

111223 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

111224 *TZ* Determine the timezone to be used for interpreting the *time* option-argument. If *TZ*
111225 is unset or null, an unspecified default timezone shall be used.

111226 **ASYNCHRONOUS EVENTS**

111227 Default.

111228 **STDOUT**

111229 Not used.

111230 **STDERR**

111231 The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The interpretation of time is taken to be *seconds since the Epoch* (see XBD Section 4.16, on page 113). It should be noted that implementations conforming to the System Interfaces volume of POSIX.1-2017 do not take leap seconds into account when computing seconds since the Epoch. When *SS*=60 is used, the resulting time always refers to 1 plus *seconds since the Epoch* for a time when *SS*=59.

Although the **−t** *time* option-argument specifies values in 1969, the access time and modification time fields are defined in terms of seconds since the Epoch (00:00:00 on 1 January 1970 UTC). Therefore, depending on the value of *TZ* when *touch* is run, there is never more than a few valid hours in 1969 and there need not be any valid times in 1969.

If the *T* time designator is replaced by a <space> for the **−d** *date_time* option-argument, the <space> must be quoted to prevent the shell from splitting the argument.

EXAMPLES

Create or update a file called **dwc**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 local time:

```
touch −d 2007−11−12T10:15:30 dwc
```

Create or update a file called **nick**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 UTC:

```
touch −d 2007−11−12T10:15:30Z nick
```

Create or update a file called **gwc**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 local time with a fractional second timestamp of .002 seconds:

```
touch −d 2007−11−12T10:15:30,002 gwc
```

Create or update a file called **ajosey**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 UTC with a fractional second timestamp of .002 seconds:

```
touch −d "2007−11−12 10:15:30.002Z" ajosey
```

Create or update a file called **cathy**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:00 local time:

```
touch −t 200711121015 cathy
```

Create or update a file called **drepper**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 local time:

```
touch -t 200711121015.30 drepper
```

Create or update a file called **ebb9**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 local time:

```
touch -t 0711121015.30 ebb9
```

Create or update a file called **eggert**; the resulting file has the last data access timestamp set to the corresponding time of the file named **mark** instead of the current time. If the file exists, the last data modification time is not changed:

```
touch -a -r mark eggert
```

RATIONALE

The functionality of *touch* is described almost entirely through references to functions in the System Interfaces volume of POSIX.1-2017. In this way, there is no duplication of effort required for describing such side-effects as the relationship of user IDs to the user database, permissions, and so on.

There are some significant differences between the *touch* utility in this volume of POSIX.1-2017 and those in System V and BSD systems. They are upwards-compatible for historical applications from both implementations:

1. In System V, an ambiguity exists when a pathname that is a decimal number leads the operands; it is treated as a time value. In BSD, no *time* value is allowed; files may only be *touch*ed to the current time. The **−t** *time* construct solves these problems for future conforming applications (note that the **−t** option is not historical practice).
2. The inclusion of the century digits, *CC*, is also new. Note that a ten-digit *time* value is treated as if *YY*, and not *CC*, were specified. The caveat about the range of dates following the Epoch was included as recognition that some implementations are not able to represent dates beyond 18 January 2038 because they use **signed int** as a time holder.

The **−r** option was added because several comments requested this capability. This option was named **−f** in an early proposal, but was changed because the **−f** option is used in the BSD version of *touch* with a different meaning.

At least one historical implementation of *touch* incremented the exit code if **−c** was specified and the file did not exist. This volume of POSIX.1-2017 requires exit status zero if no errors occur.

In previous version of the standard, if at least two operands are specified, and the first operand is an eight or ten-digit decimal integer, the first operand was assumed to be a *date_time* operand. This usage was removed in this version of the standard since it had been marked obsolescent previously.

The **−d** *date_time* format is an ISO 8601:2004 standard complete representation of date and time extended format with an optional decimal point or <comma> followed by a string of digits following the seconds portion to specify fractions of a second. It is not necessary to recognize `"[+/-]hh:mm"` and `"[+/-]hh"` to specify timezones other than local time and UTC. The *T* time designator in the ISO 8601:2004 standard extended format may be replaced by <space>.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent *date_time* operand is removed.

The Open Group Corrigendum U027/1 is applied. This extends the range of valid time past the Epoch to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal Time. This is a new requirement on POSIX implementations.

The range for seconds is changed from [00,61] to [00,60] to align with the ISO/IEC 9899:1999 standard, and to allow for positive leap seconds.

Issue 7

Austin Group Interpretation 1003.1-2001 #118 is applied.

Austin Group Interpretation 1003.1-2001 #193 is applied, adding support for subsecond timestamps.

SD5-XCU-ERN-45 is applied, adding a new paragraph to the RATIONALE.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-110 is applied, updating the OPTIONS section.

Changes are made related to support for finegrained timestamps.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0195 [474] is applied.

NAME

tput ‡'change terminal characteristics

SYNOPSIS

```
tput [−T type] operand...
```

DESCRIPTION

The *tput* utility shall display terminal-dependent information. The manner in which this information is retrieved is unspecified. The information displayed shall clear the terminal screen, initialize the user's terminal, or reset the user's terminal, depending on the operand given. The exact consequences of displaying this information are unspecified.

OPTIONS

The *tput* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

−T *type* Indicate the type of terminal. If this option is not supplied and the *TERM* variable is unset or null, an unspecified default terminal type shall be used. The setting of *type* shall take precedence over the value in *TERM*.

OPERANDS

The following strings shall be supported as operands by the implementation in the POSIX locale:

clear Display the clear-screen sequence.

init Display the sequence that initializes the user's terminal in an implementation-defined manner.

reset Display the sequence that resets the user's terminal in an implementation-defined manner.

If a terminal does not support any of the operations described by these operands, this shall not be considered an error condition.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tput*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

111377 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

111378 *TERM* Determine the terminal type. If this variable is unset or null, and if the **−T** option is
111379 not specified, an unspecified default terminal type shall be used.

111380 **ASYNCHRONOUS EVENTS**
111381 Default.

111382 **STDOUT**
111383 If standard output is a terminal device, it may be used for writing the appropriate sequence to
111384 clear the screen or reset or initialize the terminal. If standard output is not a terminal device,
111385 undefined results occur.

111386 **STDERR**
111387 The standard error shall be used only for diagnostic messages.

111388 **OUTPUT FILES**
111389 None.

111390 **EXTENDED DESCRIPTION**
111391 None.

111392 **EXIT STATUS**
111393 The following exit values shall be returned:

111394 0 The requested string was written successfully.

111395 1 Unspecified.

111396 2 Usage error.

111397 3 No information is available about the specified terminal type.

111398 4 The specified operand is invalid.

111399 >4 An error occurred.

111400 **CONSEQUENCES OF ERRORS**
111401 If one of the operands is not available for the terminal, *tput* continues processing the remaining
111402 operands.

111403 **APPLICATION USAGE**
111404 The difference between resetting and initializing a terminal is left unspecified, as they vary
111405 greatly based on hardware types. In general, resetting is a more severe action.

111406 Some terminals use control characters to perform the stated functions, and on such terminals it
111407 might make sense to use *tput* to store the initialization strings in a file or environment variable
111408 for later use. However, because other terminals might rely on system calls to do this work, the
111409 standard output cannot be used in a portable manner, such as the following non-portable
111410 constructs:

```
111411 ClearVar=`tput clear`
111412 tput reset | mailx −s "Wake Up" ddg
```

111413 **EXAMPLES**

111414 1. Initialize the terminal according to the type of terminal in the environmental variable
111415 *TERM*. This command can be included in a **.profile** file.

```
111416 tput init
```

2. Reset a 450 terminal.

```
tput -T 450 reset
```

RATIONALE

The list of operands was reduced to a minimum for the following reasons:

The only features chosen were those that were likely to be used by human users interacting with a terminal.

Specifying the full *terminfo* set was not considered desirable, but the standard developers did not want to select among operands.

This volume of POSIX.1-2017 does not attempt to provide applications with sophisticated terminal handling capabilities, as that falls outside of its assigned scope and intersects with the responsibilities of other standards bodies.

The difference between resetting and initializing a terminal is left unspecified as this varies greatly based on hardware types. In general, resetting is a more severe action.

The exit status of 1 is historically reserved for finding out if a Boolean operand is not set. Although the operands were reduced to a minimum, the exit status of 1 should still be reserved for the Boolean operands, for those sites that wish to support them.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Issue 7

The *tput* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

111445 **NAME**

111446 tr ‡'translate characters

111447 **SYNOPSIS**

111448 `tr [-c|-C] [-s] string1 string2`

111449 `tr -s [-c|-C] string1`

111450 `tr -d [-c|-C] string1`

111451 `tr -ds [-c|-C] string1 string2`

111452 **DESCRIPTION**

111453 The *tr* utility shall copy the standard input to the standard output with substitution or deletion
111454 of selected characters. The options specified and the *string1* and *string2* operands shall control
111455 translations that occur while copying characters and single-character collating elements.

111456 **OPTIONS**

111457 The *tr* utility shall conform to XBD Section 12.2 (on page 216).

111458 The following options shall be supported:

111459 **-c** Complement the set of values specified by *string1*. See the EXTENDED
111460 DESCRIPTION section.

111461 **-C** Complement the set of characters specified by *string1*. See the EXTENDED
111462 DESCRIPTION section.

111463 **-d** Delete all occurrences of input characters that are specified by *string1*.

111464 **-s** Replace instances of repeated characters with a single character, as described in the
111465 EXTENDED DESCRIPTION section.

111466 **OPERANDS**

111467 The following operands shall be supported:

111468 *string1*, *string2*

111469 Translation control strings. Each string shall represent a set of characters to be
111470 converted into an array of characters used for the translation. For a detailed
111471 description of how the strings are interpreted, see the EXTENDED DESCRIPTION
111472 section.

111473 **STDIN**

111474 The standard input can be any type of file.

111475 **INPUT FILES**

111476 None.

111477 **ENVIRONMENT VARIABLES**

111478 The following environment variables shall affect the execution of *tr*:

111479 *LANG* Provide a default value for the internationalization variables that are unset or null.
111480 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
111481 variables used to determine the values of locale categories.)

111482 *LC_ALL* If set to a non-empty string value, override the values of all the other
111483 internationalization variables.

111484 *LC_COLLATE*

111485 Determine the locale for the behavior of range expressions and equivalence classes.

111486 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
111487 characters (for example, single-byte as opposed to multi-byte characters in
111488 arguments) and the behavior of character classes.

111489 *LC_MESSAGES*
111490 Determine the locale that should be used to affect the format and contents of
111491 diagnostic messages written to standard error.

111492 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

111493 **ASYNCHRONOUS EVENTS**
111494 Default.

111495 **STDOUT**
111496 The *tr* output shall be identical to the input, with the exception of the specified transformations.

111497 **STDERR**
111498 The standard error shall be used only for diagnostic messages.

111499 **OUTPUT FILES**
111500 None.

111501 **EXTENDED DESCRIPTION**
111502 The operands *string1* and *string2* (if specified) define two arrays of characters. The constructs in
111503 the following list can be used to specify characters or single-character collating elements. If any
111504 of the constructs result in multi-character collating elements, *tr* shall exclude, without a
111505 diagnostic, those multi-character elements from the resulting array.

111506 *character* Any character not described by one of the conventions below shall represent itself.

111507 *\octal* Octal sequences can be used to represent characters with specific coded values. An
111508 octal sequence shall consist of a <backslash> followed by the longest sequence of
111509 one, two, or three-octal-digit characters (01234567). The sequence shall cause the
111510 value whose encoding is represented by the one, two, or three-digit octal integer to
111511 be placed into the array. Multi-byte characters require multiple, concatenated
111512 escape sequences of this type, including the leading <backslash> for each byte.

111513 *\character* The <backslash>-escape sequences in XBD Table 5-1 (on page 121) (`'\\'`, `'\a'`,
111514 `'\b'`,`'\f'`,`'\n'`,`'\r'`,`'\t'`,`'\v'`) shall be supported. The results of using any
111515 other character, other than an octal digit, following the <backslash> are
111516 unspecified. Also, if there is no character following the <backslash>, the results are
111517 unspecified.

111518 *c–c* In the POSIX locale, this construct shall represent the range of collating elements
111519 between the range endpoints (as long as neither endpoint is an octal sequence of
111520 the form *\octal*), inclusive, as defined by the collation sequence. The characters or
111521 collating elements in the range shall be placed in the array in ascending collation
111522 sequence. If the second endpoint precedes the starting endpoint in the collation
111523 sequence, it is unspecified whether the range of collating elements is empty, or this
111524 construct is treated as invalid. In locales other than the POSIX locale, this construct
111525 has unspecified behavior.

111526 If either or both of the range endpoints are octal sequences of the form *\octal*, this
111527 shall represent the range of specific coded values between the two range
111528 endpoints, inclusive.

111529 [:*class*:] Represents all characters belonging to the defined character class, as defined by the
111530 current setting of the *LC_CTYPE* locale category. The following character class
111531 names shall be accepted when specified in *string1*:

111532 **alnum blank digit lower punct upper**
111533 **alpha cntrl graph print space xdigit**

111534 XSI In addition, character class expressions of the form [:*name*:] shall be recognized in
111535 those locales where the *name* keyword has been given a **charclass** definition in the
111536 *LC_CTYPE* category.

111537 When both the −**d** and −**s** options are specified, any of the character class names
111538 shall be accepted in *string2*. Otherwise, only character class names **lower** or **upper**
111539 are valid in *string2* and then only if the corresponding character class (**upper** and
111540 **lower**, respectively) is specified in the same relative position in *string1*. Such a
111541 specification shall be interpreted as a request for case conversion. When [:*lower*:]
111542 appears in *string1* and [:*upper*:] appears in *string2*, the arrays shall contain the
111543 characters from the **toupper** mapping in the *LC_CTYPE* category of the current
111544 locale. When [:*upper*:] appears in *string1* and [:*lower*:] appears in *string2*, the arrays
111545 shall contain the characters from the **tolower** mapping in the *LC_CTYPE* category
111546 of the current locale. The first character from each mapping pair shall be in the
111547 array for *string1* and the second character from each mapping pair shall be in the
111548 array for *string2* in the same relative position.

111549 Except for case conversion, the characters specified by a character class expression
111550 shall be placed in the array in an unspecified order.

111551 If the name specified for *class* does not define a valid character class in the current
111552 locale, the behavior is undefined.

111553 [=*equiv*=] Represents all characters or collating elements belonging to the same equivalence
111554 class as *equiv*, as defined by the current setting of the *LC_COLLATE* locale category.
111555 An equivalence class expression shall be allowed only in *string1*, or in *string2* when
111556 it is being used by the combined −**d** and −**s** options. The characters belonging to
111557 the equivalence class shall be placed in the array in an unspecified order.

111558 [*x***n*] Represents *n* repeated occurrences of the character *x*. Because this expression is
111559 used to map multiple characters to one, it is only valid when it occurs in *string2*. If
111560 *n* is omitted or is zero, it shall be interpreted as large enough to extend the
111561 *string2*-based sequence to the length of the *string1*-based sequence. If *n* has a
111562 leading zero, it shall be interpreted as an octal value. Otherwise, it shall be
111563 interpreted as a decimal value.

111564 When the −**d** option is not specified:

111565 If *string2* is present, each input character found in the array specified by *string1* shall be
111566 replaced by the character in the same relative position in the array specified by *string2*. If
111567 the array specified by *string2* is shorter that the one specified by *string1*, or if a character
111568 occurs more than once in *string1*, the results are unspecified.

111569 If the −**C** option is specified, the complements of the characters specified by *string1* (the set
111570 of all characters in the current character set, as defined by the current setting of *LC_CTYPE*,
111571 except for those actually specified in the *string1* operand) shall be placed in the array in
111572 ascending collation sequence, as defined by the current setting of *LC_COLLATE*.

111573 If the −**c** option is specified, the complement of the values specified by *string1* shall be
111574 placed in the array in ascending order by binary value.

111575 Because the order in which characters specified by character class expressions or
111576 equivalence class expressions is undefined, such expressions should only be used if the
111577 intent is to map several characters into one. An exception is case conversion, as described
111578 previously.

111579 When the −**d** option is specified:

111580 Input characters found in the array specified by *string1* shall be deleted.

111581 When the −**C** option is specified with −**d**, all characters except those specified by *string1*
111582 shall be deleted. The contents of *string2* are ignored, unless the −**s** option is also specified.

111583 When the −**c** option is specified with −**d**, all values except those specified by *string1* shall
111584 be deleted. The contents of *string2* shall be ignored, unless the −**s** option is also specified.

111585 The same string cannot be used for both the −**d** and the −**s** option; when both options are
111586 specified, both *string1* (used for deletion) and *string2* (used for squeezing) shall be
111587 required.

111588 When the −**s** option is specified, after any deletions or translations have taken place, repeated
111589 sequences of the same character shall be replaced by one occurrence of the same character, if the
111590 character is found in the array specified by the last operand. If the last operand contains a
111591 character class, such as the following example:

111592 `tr −s '[:space:]'`

111593 the last operand's array shall contain all of the characters in that character class. However, in a
111594 case conversion, as described previously, such as:

111595 `tr −s '[:upper:]' '[:lower:]'`

111596 the last operand's array shall contain only those characters defined as the second characters in
111597 each of the **toupper** or **tolower** character pairs, as appropriate.

111598 An empty string used for *string1* or *string2* produces undefined results.

111599 **EXIT STATUS**

111600 The following exit values shall be returned:

111601 0 All input was processed successfully.

111602 >0 An error occurred.

111603 **CONSEQUENCES OF ERRORS**

111604 Default.

111605 **APPLICATION USAGE**

111606 If necessary, *string1* and *string2* can be quoted to avoid pattern matching by the shell.

111607 If an ordinary digit (representing itself) is to follow an octal sequence, the octal sequence must
111608 use the full three digits to avoid ambiguity.

111609 When *string2* is shorter than *string1*, a difference results between historical System V and BSD
111610 systems. A BSD system pads *string2* with the last character found in *string2*. Thus, it is possible
111611 to do the following:

111612 `tr 0123456789 d`

111613 which would translate all digits to the letter `'d'`. Since this area is specifically unspecified in

this volume of POSIX.1-2017, both the BSD and System V behaviors are allowed, but a conforming application cannot rely on the BSD behavior. It would have to code the example in the following way:

```
tr 0123456789 '[d*]'
```

It should be noted that, despite similarities in appearance, the string operands used by *tr* are not regular expressions.

Unlike some historical implementations, this definition of the *tr* utility correctly processes NUL characters in its input stream. NUL characters can be stripped by using:

```
tr -d '\000'
```

EXAMPLES

1. The following example creates a list of all words in **file1** one per line in **file2**, where a word is taken to be a maximal string of letters.

   ```
   tr -cs "[:alpha:]" "[\n*]" <file1 >file2
   ```

2. The next example translates all lowercase characters in **file1** to uppercase and writes the results to standard output.

   ```
   tr "[:lower:]" "[:upper:]" <file1
   ```

3. This example uses an equivalence class to identify accented variants of the base character `'e'` in **file1**, which are stripped of diacritical marks and written to **file2**.

   ```
   tr "[=e=]" "[e*]" <file1 >file2
   ```

RATIONALE

In some early proposals, an explicit option **-n** was added to disable the historical behavior of stripping NUL characters from the input. It was considered that automatically stripping NUL characters from the input was not correct functionality. However, the removal of **-n** in a later proposal does not remove the requirement that *tr* correctly process NUL characters in its input stream. NUL characters can be stripped by using *tr* **-d** '\000'.

Historical implementations of *tr* differ widely in syntax and behavior. For example, the BSD version has not needed the bracket characters for the repetition sequence. The *tr* utility syntax is based more closely on the System V and XPG3 model while attempting to accommodate historical BSD implementations. In the case of the short *string2* padding, the decision was to unspecify the behavior and preserve System V and XPG3 scripts, which might find difficulty with the BSD method. The assumption was made that BSD users of *tr* have to make accommodations to meet the syntax defined here. Since it is possible to use the repetition sequence to duplicate the desired behavior, whereas there is no simple way to achieve the System V method, this was the correct, if not desirable, approach.

The use of octal values to specify control characters, while having historical precedents, is not portable. The introduction of escape sequences for control characters should provide the necessary portability. It is recognized that this may cause some historical scripts to break.

An early proposal included support for multi-character collating elements. It was pointed out that, while *tr* does employ some syntactical elements from REs, the aim of *tr* is quite different; ranges, for example, do not have a similar meaning (``any of the chars in the range matches'', *versus* ``translate each character in the range to the output counterpart''). As a result, the previously included support for multi-character collating elements has been removed. What remains are ranges in current collation order (to support, for example, accented characters), character classes, and equivalence classes.

In XPG3 the [:*class*:] and [=*equiv*=] conventions are shown with double brackets, as in RE syntax. However, *tr* does not implement RE principles; it just borrows part of the syntax. Consequently, [:*class*:] and [=*equiv*=] should be regarded as syntactical elements on a par with [*x***n*], which is not an RE bracket expression.

The standard developers will consider changes to *tr* that allow it to translate characters between different character encodings, or they will consider providing a new utility to accomplish this.

On historical System V systems, a range expression requires enclosing square-brackets, such as:

```
tr '[a-z]' '[A-Z]'
```

However, BSD-based systems did not require the brackets, and this convention is used here to avoid breaking large numbers of BSD scripts:

```
tr a-z A-Z
```

The preceding System V script will continue to work because the brackets, treated as regular characters, are translated to themselves. However, any System V script that relied on `"a-z"` representing the three characters `'a'`, `'-'`, and `'z'` have to be rewritten as `"az-"`.

The ISO POSIX-2: 1993 standard had a **−c** option that behaved similarly to the **−C** option, but did not supply functionality equivalent to the **−c** option specified in POSIX.1-2017.

The earlier version also said that octal sequences referred to collating elements and could be placed adjacent to each other to specify multi-byte characters. However, it was noted that this caused ambiguities because *tr* would not be able to tell whether adjacent octal sequences were intending to specify multi-byte characters or multiple single byte characters. POSIX.1-2017 specifies that octal sequences always refer to single byte binary values when used to specify an endpoint of a range of collating elements.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The **−C** operand is added, and the description of the **−c** operand is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/31 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/32 is applied, updating an example in the EXAMPLES section to avoid using unspecified behavior.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/33 is applied, making a correction to the RATIONALE.

Issue 7

SD5-XCU-ERN-30 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #132 is applied, adding rationale to the *character* construct.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0145 [325] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0196 [663] is applied.

NAME

true — return true value

SYNOPSIS

```
true
```

DESCRIPTION

The *true* utility shall return with exit code zero.

OPTIONS

None.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Not used.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

Zero.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

This utility is typically used in shell scripts, as shown in the EXAMPLES section. The special built-in utility **:** is sometimes more efficient than *true*.

EXAMPLES

This command is executed forever:

```
while true
do
    command
done
```

RATIONALE

The *true* utility has been retained in this volume of POSIX.1-2017, even though the shell special built-in **:** provides similar functionality, because *true* is widely used in historical scripts and is less cryptic to novice script readers.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/39 is applied, replacing the terms ``None'' and ``Default'' from the STDERR and EXIT STATUS sections, respectively, with terms as defined in Section 1.4 (on page 2336).

111759 **NAME**

111760 tsort ‡'topological sort

111761 **SYNOPSIS**

111762 `tsort [`*`file`*`]`

111763 **DESCRIPTION**

111764 The *tsort* utility shall write to standard output a totally ordered list of items consistent with a
111765 partial ordering of items contained in the input.

111766 The application shall ensure that the input consists of pairs of items (non-empty strings)
111767 separated by <blank> characters. Pairs of different items indicate ordering. Pairs of identical
111768 items indicate presence, but not ordering.

111769 **OPTIONS**

111770 None.

111771 **OPERANDS**

111772 The following operand shall be supported:

111773 *file* A pathname of a text file to order. If no *file* operand is given, the standard input
111774 shall be used.

111775 **STDIN**

111776 The standard input shall be used if no *file* operand is specified, and shall be used if the *file*
111777 operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise,
111778 the standard input shall not be used. See the INPUT FILES section.

111779 **INPUT FILES**

111780 The input file shall be a text file.

111781 **ENVIRONMENT VARIABLES**

111782 The following environment variables shall affect the execution of *tsort*:

111783 *LANG* Provide a default value for the internationalization variables that are unset or null.
111784 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
111785 variables used to determine the values of locale categories.)

111786 *LC_ALL* If set to a non-empty string value, override the values of all the other
111787 internationalization variables.

111788 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
111789 characters (for example, single-byte as opposed to multi-byte characters in
111790 arguments and input files).

111791 *LC_MESSAGES*

111792 Determine the locale that should be used to affect the format and contents of
111793 diagnostic messages written to standard error.

111794 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

111795 **ASYNCHRONOUS EVENTS**

111796 Default.

111797 **STDOUT**

111798 The standard output shall be a text file consisting of the order list produced from the partially
111799 ordered input.

111800 **STDERR**

111801 The standard error shall be used only for diagnostic messages.

111802 **OUTPUT FILES**

111803 None.

111804 **EXTENDED DESCRIPTION**

111805 None.

111806 **EXIT STATUS**

111807 The following exit values shall be returned:

111808 0 Successful completion.

111809 >0 An error occurred.

111810 **CONSEQUENCES OF ERRORS**

111811 Default.

111812 **APPLICATION USAGE**

111813 The *LC_COLLATE* variable need not affect the actions of *tsort*. The output ordering is not
111814 lexicographic, but depends on the pairs of items given as input.

111815 **EXAMPLES**

111816 The command:

```
111817 tsort <<EOF
111818 a b c c d e
111819 g g
111820 f g e f
111821 h h
111822 EOF
```

111823 produces the output:

```
111824 a
111825 b
111826 c
111827 d
111828 e
111829 f
111830 g
111831 h
```

111832 **RATIONALE**

111833 None.

111834 **FUTURE DIRECTIONS**

111835 None.

111836 **SEE ALSO**

111837 XBD Chapter 8 (on page 173)

111838 **CHANGE HISTORY**

111839 First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

The *tsort* utility is moved from the XSI option to the Base.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0146 [241] is applied.

NAME

tty — return user's terminal name

SYNOPSIS

```
tty
```

DESCRIPTION

The *tty* utility shall write to the standard output the name of the terminal that is open as standard input. The name that is used shall be equivalent to the string that would be returned by the *ttyname*( ) function defined in the System Interfaces volume of POSIX.1-2017.

OPTIONS

The *tty* utility shall conform to XBD Section 12.2 (on page 216).

OPERANDS

None.

STDIN

While no input is read from standard input, standard input shall be examined to determine whether or not it is a terminal, and, if so, to determine the name of the terminal.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tty*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If standard input is a terminal device, a pathname of the terminal as specified by the *ttyname*( ) function defined in the System Interfaces volume of POSIX.1-2017 shall be written in the following format:

```
"%s\n", <terminal name>
```

Otherwise, a message shall be written indicating that standard input is not connected to a terminal. In the POSIX locale, the *tty* utility shall use the format:

```
"not a tty\n"
```

111888 **STDERR**

111889 The standard error shall be used only for diagnostic messages.

111890 **OUTPUT FILES**

111891 None.

111892 **EXTENDED DESCRIPTION**

111893 None.

111894 **EXIT STATUS**

111895 The following exit values shall be returned:

111896 0 Standard input is a terminal.

111897 1 Standard input is not a terminal.

111898 >1 An error occurred.

111899 **CONSEQUENCES OF ERRORS**

111900 Default.

111901 **APPLICATION USAGE**

111902 This utility checks the status of the file open as standard input against that of an
111903 implementation-defined set of files. It is possible that no match can be found, or that the match
111904 found need not be the same file as that which was opened for standard input (although they are
111905 the same device).

111906 **EXAMPLES**

111907 None.

111908 **RATIONALE**

111909 None.

111910 **FUTURE DIRECTIONS**

111911 None.

111912 **SEE ALSO**

111913 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

111914 XSH *isatty*( ), *ttyname*( )

111915 **CHANGE HISTORY**

111916 First released in Issue 2.

111917 **Issue 5**

111918 The SYNOPSIS is changed to indicate two forms of the command, with the second form marked
111919 as obsolete. This is a clarification and does not change the functionality published in previous
111920 issues.

111921 **Issue 6**

111922 The obsolescent **−s** option is removed.

NAME

type ‡'write a description of command type

SYNOPSIS

XSI

```
type name...
```

DESCRIPTION

The *type* utility shall indicate how each argument would be interpreted if used as a command name.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

name A name to be interpreted.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *type*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the location of *name*, as described in XBD Chapter 8 (on page 173).

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output of *type* contains information about each operand in an unspecified format. The information provided typically identifies the operand as a shell built-in, function, alias, or keyword, and where applicable, may display the operand's pathname.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *type* must be aware of the contents of the current shell execution environment (such as the lists of commands, functions, and built-ins processed by *hash*), it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:

```
nohup type writer
find . −type f | xargs type
```

it might not produce accurate results.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

ulimit — set or report file size limit

SYNOPSIS

XSI

```
ulimit [-f] [blocks]
```

DESCRIPTION

The *ulimit* utility shall set or report the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.

OPTIONS

The *ulimit* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-f Set (or report, if no *blocks* operand is present), the file size limit in blocks. The **-f** option shall also be the default case.

OPERANDS

The following operand shall be supported:

blocks The number of 512-byte blocks to use as the new file size limit.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ulimit*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used when no *blocks* operand is present. If the current number of blocks is limited, the number of blocks in the current limit shall be written in the following format:

```
"%d\n", <number of 512-byte blocks>
```

If there is no current limit on the number of blocks, in the POSIX locale the following format

shall be used:

```
"unlimited\n"
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 A request for a higher limit was rejected or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *ulimit* affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:

```
nohup ulimit -f 10000
env ulimit 10000
```

it does not affect the file size limit of the caller's environment.

Once a limit has been decreased by a process, it cannot be increased (unless appropriate privileges are involved), even back to the original system limit.

EXAMPLES

Set the file size limit to 51 200 bytes:

```
ulimit -f 100
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

umask — get or set the file mode creation mask

SYNOPSIS

```
umask [-S] [mask]
```

DESCRIPTION

The *umask* utility shall set the file mode creation mask of the current shell execution environment (see Section 2.12, on page 2381) to the value specified by the *mask* operand. This mask shall affect the initial value of the file permission bits of subsequently created files. If *umask* is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . -exec umask ... \;
```

it shall not affect the file mode creation mask of the caller's environment.

If the *mask* operand is not specified, the *umask* utility shall write to standard output the value of the file mode creation mask of the invoking process.

OPTIONS

The *umask* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-S Produce symbolic output.

The default output style is unspecified, but shall be recognized on a subsequent invocation of *umask* on the same system as a *mask* operand to restore the previous file mode creation mask.

OPERANDS

The following operand shall be supported:

mask A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the EXTENDED DESCRIPTION section for *chmod*.

For a *symbolic_mode* value, the new value of the file mode creation mask shall be the logical complement of the file permission bits portion of the file mode specified by the *symbolic_mode* string.

In a *symbolic_mode* value, the permissions *op* characters `'+'` and `'-'` shall be interpreted relative to the current file mode creation mask; `'+'` shall cause the bits for the indicated permissions to be cleared in the mask; `'-'` shall cause the bits for the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

In the octal integer form of *mode*, the specified bits are set in the file mode creation mask.

The file mode creation mask shall be set to the resulting numeric value.

The default output of a prior invocation of *umask* on the same system with no operand also shall be recognized as a *mask* operand.

112110 **STDIN**

112111 Not used.

112112 **INPUT FILES**

112113 None.

112114 **ENVIRONMENT VARIABLES**

112115 The following environment variables shall affect the execution of *umask*:

112116 *LANG* Provide a default value for the internationalization variables that are unset or null.
112117 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
112118 variables used to determine the values of locale categories.)

112119 *LC_ALL* If set to a non-empty string value, override the values of all the other
112120 internationalization variables.

112121 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
112122 characters (for example, single-byte as opposed to multi-byte characters in
112123 arguments).

112124 *LC_MESSAGES*
112125 Determine the locale that should be used to affect the format and contents of
112126 diagnostic messages written to standard error.

112127 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

112128 **ASYNCHRONOUS EVENTS**

112129 Default.

112130 **STDOUT**

112131 When the *mask* operand is not specified, the *umask* utility shall write a message to standard
112132 output that can later be used as a *umask mask* operand.

112133 If **–S** is specified, the message shall be in the following format:

112134 `"u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>,`
112135 `<other permissions>`

112136 where the three values shall be combinations of letters from the set {*r*, *w*, *x*}; the presence of a
112137 letter shall indicate that the corresponding bit is clear in the file mode creation mask.

112138 If a *mask* operand is specified, there shall be no output written to standard output.

112139 **STDERR**

112140 The standard error shall be used only for diagnostic messages.

112141 **OUTPUT FILES**

112142 None.

112143 **EXTENDED DESCRIPTION**

112144 None.

112145 **EXIT STATUS**

112146 The following exit values shall be returned:

112147 0 The file mode creation mask was successfully changed, or no *mask* operand was supplied.

112148 >0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *umask* affects the current shell execution environment, it is generally provided as a shell regular built-in.

In contrast to the negative permission logic provided by the file mode creation mask and the octal number form of the *mask* argument, the symbolic form of the *mask* argument specifies those permissions that are left alone.

EXAMPLES

Either of the commands:

```
umask a=rx,ug+w
umask 002
```

sets the mode mask so that subsequently created files have their S_IWOTH bit cleared.

After setting the mode mask with either of the above commands, the *umask* command can be used to write out the current value of the mode mask:

```
$ umask
0002
```

(The output format is unspecified, but historical implementations use the octal integer mode format.)

```
$ umask -S
u=rwx,g=rwx,o=rx
```

Either of these outputs can be used as the mask operand to a subsequent invocation of the *umask* utility.

Assuming the mode mask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their S_IWGRP and S_IWOTH bits cleared.

The command:

```
umask -- -w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Note that *mask* operands **-r**, **-w**, **-x** or anything beginning with a <hyphen-minus>, must be preceded by `"--"` to keep it from being interpreted as an option.

RATIONALE

Since *umask* affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . -exec umask ... \;
```

it does not affect the file mode creation mask of the environment of the caller.

The description of the historical utility was modified to allow it to use the symbolic modes of

chmod. The **−s** option used in early proposals was changed to **−S** because **−s** could be confused with a *symbolic_mode* form of mask referring to the S_ISUID and S_ISGID bits.

The default output style is unspecified to permit implementors to provide migration to the new symbolic style at the time most appropriate to their users. A **−o** flag to force octal mode output was omitted because the octal mode may not be sufficient to specify all of the information that may be present in the file mode creation mask when more secure file access permission checks are implemented.

It has been suggested that trusted systems developers might appreciate ameliorating the requirement that the mode mask ``affects'' the file access permissions, since it seems access control lists might replace the mode mask to some degree. The wording has been changed to say that it affects the file permission bits, and it leaves the details of the behavior of how they affect the file access permissions to the description in the System Interfaces volume of POSIX.1-2017.

FUTURE DIRECTIONS

None.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

> The octal mode is supported.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/34 is applied, making a correction to the RATIONALE.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0197 [584] is applied.

NAME

unalias — remove alias definitions

SYNOPSIS

```
unalias alias-name...
unalias -a
```

DESCRIPTION

The *unalias* utility shall remove the definition for each alias name specified. See Section 2.3.1 (on page 2348). The aliases shall be removed from the current shell execution environment; see Section 2.12 (on page 2381).

OPTIONS

The *unalias* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-a Remove all alias definitions from the current shell execution environment.

OPERANDS

The following operand shall be supported:

alias-name The name of an alias to be removed.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unalias*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 One of the *alias-name* operands specified did not represent a valid alias definition, or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *unalias* affects the current shell execution environment, it is generally provided as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The *unalias* description is based on that from historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of POSIX.1-2017, such as command line editing.

The **−a** option is the equivalent of the *unalias* * form of the C shell and is provided to address security concerns about unknown aliases entering the environment of a user (or application) through the allowable implementation-defined predefined alias route or as a result of an *ENV* file. (Although *unalias* could be used to simplify the ``secure'' shell script shown in the *command* rationale, it does not obviate the need to quote all command names. An initial call to *unalias* **−a** would have to be quoted in case there was an alias for *unalias*.)

FUTURE DIRECTIONS

None.

SEE ALSO

Chapter 2 (on page 2345), *alias*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Issue 7

The *unalias* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

uname — return system name

SYNOPSIS

```
uname [−amnrsv]
```

DESCRIPTION

By default, the *uname* utility shall write the operating system name to standard output. When options are specified, symbols representing one or more system characteristics shall be written to the standard output. The format and contents of the symbols are implementation-defined. On systems conforming to the System Interfaces volume of POSIX.1-2017, the symbols written shall be those supported by the *uname*( ) function as defined in the System Interfaces volume of POSIX.1-2017.

OPTIONS

The *uname* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−a Behave as though all of the options **−mnrsv** were specified.

−m Write the name of the hardware type on which the system is running to standard output.

−n Write the name of this node within an implementation-defined communications network.

−r Write the current release level of the operating system implementation.

−s Write the name of the implementation of the operating system.

−v Write the current version level of this release of the operating system implementation.

If no options are specified, the *uname* utility shall write the operating system name, as if the **−s** option had been specified.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uname*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
By default, the output shall be a single line of the following form:

```
"%s\n", <sysname>
```

If the **−a** option is specified, the output shall be a single line of the following form:

```
"%s %s %s %s %s\n", <sysname>, <nodename>, <release>,
    <version>, <machine>
```

Additional implementation-defined symbols may be written; all such symbols shall be written at the end of the line of output before the <newline>.

If options are specified to select different combinations of the symbols, only those symbols shall be written, in the order shown above for the **−a** option. If a symbol is not selected for writing, its corresponding trailing <blank> characters also shall not be written.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 The requested information was successfully written.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Note that any of the symbols could include embedded <space> characters, which may affect parsing algorithms if multiple options are selected for output.

The node name is typically a name that the system uses to identify itself for inter-system communication addressing.

EXAMPLES
The following command:

```
uname −sr
```

writes the operating system name and release level, separated by one or more <blank> characters.

RATIONALE

It was suggested that this utility cannot be used portably since the format of the symbols is implementation-defined. The POSIX.1 working group could not achieve consensus on defining these formats in the underlying *uname*( ) function, and there was no expectation that this volume of POSIX.1-2017 would be any more successful. Some applications may still find this historical utility of value. For example, the symbols could be used for system log entries or for comparison with operator or user input.

FUTURE DIRECTIONS

None.

XSH *uname*( )

CHANGE HISTORY

First released in Issue 2.

NAME

uncompress — expand compressed data

SYNOPSIS

XSI

```
uncompress [–cfv] [file...]
```

DESCRIPTION

The *uncompress* utility shall restore files to their original state after they have been compressed using the *compress* utility. If no files are specified, the standard input shall be uncompressed to the standard output. If the invoking process has appropriate privileges, the ownership, modes, access time, and modification time of the original file shall be preserved.

This utility shall support the uncompressing of any files produced by the *compress* utility on the same implementation. For files produced by *compress* on other systems, *uncompress* supports 9 to 14-bit compression (see *compress*, **–b**); it is implementation-defined whether values of **–b** greater than 14 are supported.

OPTIONS

The *uncompress* utility shall conform to XBD Section 12.2 (on page 216), except that Guideline 1 does apply since the utility name has ten letters.

The following options shall be supported:

–c Write to standard output; no files are changed.

–f Do not prompt for overwriting files. Except when run in the background, if **–f** is not given the user shall be prompted as to whether an existing file should be overwritten. If the standard input is not a terminal and **–f** is not given, *uncompress* shall write a diagnostic message to standard error and exit with a status greater than zero.

–v Write messages to standard error concerning the expansion of each file.

OPERANDS

The following operand shall be supported:

file A pathname of a file. If *file* already has the **.Z** suffix specified, it shall be used as the input file and the output file shall be named **file** with the **.Z** suffix removed. Otherwise, *file* shall be used as the name of the output file and **file** with the **.Z** suffix appended shall be used as the input file.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

INPUT FILES

Input files shall be in the format produced by the *compress* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uncompress*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

112433 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
112434 characters (for example, single-byte as opposed to multi-byte characters in
112435 arguments).

112436 *LC_MESSAGES*
112437 Determine the locale that should be used to affect the format and contents of
112438 diagnostic messages written to standard error.

112439 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

112440 **ASYNCHRONOUS EVENTS**
112441 Default.

112442 **STDOUT**
112443 When there are no *file* operands or the **−c** option is specified, the uncompressed output is written
112444 to standard output.

112445 **STDERR**
112446 Prompts shall be written to the standard error output under the conditions specified in the
112447 DESCRIPTION and OPTIONS sections. The prompts shall contain the *file* pathname, but their
112448 format is otherwise unspecified. Otherwise, the standard error output shall be used only for
112449 diagnostic messages.

112450 **OUTPUT FILES**
112451 Output files are the same as the respective input files to *compress*.

112452 **EXTENDED DESCRIPTION**
112453 None.

112454 **EXIT STATUS**
112455 The following exit values shall be returned:

112456 0 Successful completion.

112457 >0 An error occurred.

112458 **CONSEQUENCES OF ERRORS**
112459 The input file remains unmodified.

112460 **APPLICATION USAGE**
112461 The limit of 14 on the *compress* **−b** *bits* argument is to achieve portability to all systems (within
112462 the restrictions imposed by the lack of an explicit published file format). Some implementations
112463 based on 16-bit architectures cannot support 15 or 16-bit uncompression.

112464 **EXAMPLES**
112465 None.

112466 **RATIONALE**
112467 None.

112468 **FUTURE DIRECTIONS**
112469 None.

112470 **SEE ALSO**
112471 *compress*, *zcat*

112472 XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

SD5-XCU-ERN-26 is applied, clarifying that this utility is allowed to break the Utility Syntax Guidelines by having ten letters in its name.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

unexpand ‡'convert spaces to tabs

SYNOPSIS

```
unexpand [-a|-t tablist] [file...]
```

DESCRIPTION

The *unexpand* utility shall copy files or standard input to standard output, converting <blank> characters at the beginning of each line into the maximum number of <tab> characters followed by the minimum number of <space> characters needed to fill the same column positions originally filled by the translated <blank> characters. By default, tabstops shall be set at every eighth column position. Each <backspace> shall be copied to the output, and shall cause the column position count for tab calculations to be decremented; the count shall never be decremented to a value less than one.

OPTIONS

The *unexpand* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-a In addition to translating <blank> characters at the beginning of each line, translate all sequences of two or more <blank> characters immediately preceding a tab stop to the maximum number of <tab> characters followed by the minimum number of <space> characters needed to fill the same column positions originally filled by the translated <blank> characters.

-t *tablist* Specify the tab stops. The application shall ensure that the *tablist* option-argument is a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by <blank> or <comma> characters, in ascending order. If a single number is given, tabs shall be set *tablist* column positions apart instead of the default 8. If multiple numbers are given, the tabs shall be set at those specific column positions.

The application shall ensure that each tab-stop position *N* is an integer value greater than zero, and the list shall be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line. When the **-t** option is not specified, the default shall be the equivalent of specifying **-t 8** (except for the interaction with **-a**, described below).

No <space>-to-<tab> conversions shall occur for characters at positions beyond the last of those specified in a multiple tab-stop list.

When **-t** is specified, the presence or absence of the **-a** option shall be ignored; conversion shall not be limited to the processing of leading <blank> characters.

OPERANDS

The following operand shall be supported:

file A pathname of a text file to be used as input.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unexpand*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab> and <space> characters, and for the determination of the width in column positions each character would occupy on an output device.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be equivalent to the input files with the specified <space>-to-<tab> conversions.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

One non-intuitive aspect of *unexpand* is its restriction to leading <space> characters when neither **−a** nor **−t** is specified. Users who always want to convert all <space> characters in a file can easily alias *unexpand* to use the **−a** or **−t 8** option.

EXAMPLES

None.

RATIONALE

On several occasions, consideration was given to adding a **−t** option to the *unexpand* utility to complement the **−t** in *expand* (see *expand*). The historical intent of *unexpand* was to translate multiple <blank> characters into tab stops, where tab stops were a multiple of eight column

positions on most UNIX systems. An early proposal omitted **−t** because it seemed outside the scope of the User Portability Utilities option; it was not described in any of the base documents for IEEE Std 1003.2-1992. However, hard-coding tab stops every eight columns was not suitable for the international community and broke historical precedents for some vendors in the FORTRAN community, so **−t** was restored in conjunction with the list of valid extension categories considered by the standard developers. Thus, *unexpand* is now the logical converse of *expand*.

FUTURE DIRECTIONS

None.

SEE ALSO

expand, *tabs*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The definition of the *LC_CTYPE* environment variable is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

The *unexpand* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0198 [885] is applied.

NAME

unget — undo a previous get of an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI

```
unget [−ns] [−r SID] file...
```

DESCRIPTION

The *unget* utility shall reverse the effect of a *get* **−e** done prior to creating the intended new delta.

OPTIONS

The *unget* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−r *SID* Uniquely identify which delta is no longer intended. (This would have been specified by *get* as the new delta.) The use of this option is necessary only if two or more outstanding *get* commands for editing on the same SCCS file were done by the same person (login name).

−s Suppress the writing to standard output of the intended delta's SID.

−n Retain the file that was obtained by *get*, which would normally be removed from the current directory.

OPERANDS

The following operands shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *unget* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

Any SCCS files processed shall be files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unget*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall consist of a line for each file, in the following format:

`"%s\n", <SID removed from file>`

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:

`"\n%s:\n", <pathname>`

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Any SCCS files updated shall be files of an unspecified format. During processing of a *file*, a locking *z-file*, as described in *get*, and a *q-file* (a working copy of the *p-file*), may be created and deleted. The *p-file* and *g-file*, as described in *get*, shall be deleted.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

112672 **Issue 7**
112673 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

uniq — report or filter out repeated lines in a file

SYNOPSIS

```
uniq [−c|−d|−u] [−f fields] [−s char] [input_file [output_file]]
```

DESCRIPTION

The *uniq* utility shall read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines shall not be written. The trailing <newline> of each line in the input shall be ignored when doing comparisons.

Repeated lines in the input shall not be detected if they are not adjacent.

OPTIONS

The *uniq* utility shall conform to XBD Section 12.2 (on page 216), except that `'+'` may be recognized as an option delimiter as well as `'−'`.

The following options shall be supported:

−c Precede each output line with a count of the number of times the line occurred in the input.

−d Suppress the writing of lines that are not repeated in the input.

−f *fields* Ignore the first *fields* fields on each input line when doing comparisons, where *fields* is a positive decimal integer. A field is the maximal string matched by the basic regular expression:

```
[[:blank:]]*[^[:blank:]]*
```

If the *fields* option-argument specifies more fields than appear on an input line, a null string shall be used for comparison.

−s *chars* Ignore the first *chars* characters when doing comparisons, where *chars* shall be a positive decimal integer. If specified in conjunction with the **−f** option, the first *chars* characters after the first *fields* fields shall be ignored. If the *chars* option-argument specifies more characters than remain on an input line, a null string shall be used for comparison.

−u Suppress the writing of lines that are repeated in the input.

OPERANDS

The following operands shall be supported:

input_file A pathname of the input file. If the *input_file* operand is not specified, or if the *input_file* is `'−'`, the standard input shall be used.

output_file A pathname of the output file. If the *output_file* operand is not specified, the standard output shall be used. The results are unspecified if the file named by *output_file* is the file named by *input_file*.

STDIN

The standard input shall be used only if no *input_file* operand is specified or if *input_file* is `'−'`. See the INPUT FILES section.

INPUT FILES

The input file shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uniq*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters constitute a <blank> in the current locale.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used if no *output_file* operand is specified, and shall be used if the *output_file* operand is `'-'` and the implementation treats the `'-'` as meaning standard output. Otherwise, the standard output shall not be used. See the OUTPUT FILES section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

If the **−c** option is specified, the output file shall be empty or each line shall be of the form:

`"%d %s", <number of duplicates>, <line>`

otherwise, the output file shall be empty or each line shall be of the form:

`"%s", <line>`

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the collating sequence of the current locale has a total ordering of all characters, the *sort* utility can be used to cause repeated lines to be adjacent in the input file. If the collating sequence does not have a total ordering of all characters, the *sort* utility should still do this but it might not. To ensure that all duplicate lines are eliminated, and have the output sorted according the collating sequence of the current locale, applications should use:

```
LC_ALL=C sort -u | sort
```

instead of:

```
sort | uniq
```

To remove duplicate lines based on whether they collate equally instead of whether they are identical, applications should use:

```
sort -u
```

instead of:

```
sort | uniq
```

When using *uniq* to process pathnames, it is recommended that LC_ALL, or at least LC_CTYPE and LC_COLLATE, are set to POSIX or C in the environment, since pathnames can contain byte sequences that do not form valid characters in some locales, in which case the utility's behavior would be undefined. In the POSIX locale each byte is a valid single-byte character, and therefore this problem is avoided.

EXAMPLES

The following input file data (but flushed left) was used for a test series on *uniq*:

```
#01 foo0 bar0 foo1 bar1
#02 bar0 foo1 bar1 foo1
#03 foo0 bar0 foo1 bar1
#04
#05 foo0 bar0 foo1 bar1
#06 foo0 bar0 foo1 bar1
#07 bar0 foo1 bar1 foo0
```

What follows is a series of test invocations of the *uniq* utility that use a mixture of *uniq* options against the input file data. These tests verify the meaning of *adjacent*. The *uniq* utility views the input data as a sequence of strings delimited by `'\n'`. Accordingly, for the *fields*th member of the sequence, *uniq* interprets unique or repeated adjacent lines strictly relative to the *fields*+1th member.

1. This first example tests the line counting option, comparing each line of the input file data starting from the second field:

   ```
   uniq -c -f 1 uniq_0I.t
       1 #01 foo0 bar0 foo1 bar1
       1 #02 bar0 foo1 bar1 foo1
       1 #03 foo0 bar0 foo1 bar1
       1 #04
       2 #05 foo0 bar0 foo1 bar1
       1 #07 bar0 foo1 bar1 foo0
   ```

   The number `'2'`, prefixing the fifth line of output, signifies that the *uniq* utility detected a pair of repeated lines. Given the input data, this can only be true when *uniq* is run using the **-f 1** option (which shall cause *uniq* to ignore the first field on each input line).

2. The second example tests the option to suppress unique lines, comparing each line of the input file data starting from the second field:

```
uniq -d -f 1 uniq_0I.t
#05 foo0 bar0 foo1 bar1
```

3. This test suppresses repeated lines, comparing each line of the input file data starting from the second field:

```
uniq -u -f 1 uniq_0I.t
#01 foo0 bar0 foo1 bar1
#02 bar0 foo1 bar1 foo1
#03 foo0 bar0 foo1 bar1
#04
#07 bar0 foo1 bar1 foo0
```

4. This suppresses unique lines, comparing each line of the input file data starting from the third character:

```
uniq -d -s 2 uniq_0I.t
```

In the last example, the *uniq* utility found no input matching the above criteria.

RATIONALE

Some historical implementations have limited lines to be 1 080 bytes in length, which does not meet the implied {LINE_MAX} limit.

Earlier versions of this standard allowed the *–number* and *+number* options. These options are no longer specified by POSIX.1-2017 but may be present in some implementations.

FUTURE DIRECTIONS

None.

NAME

unlink ‡'call the*unlink*( ) function

SYNOPSIS

XSI
```
unlink file
```

DESCRIPTION

The *unlink* utility shall perform the function call:

```
unlink(file);
```

A user may need appropriate privileges to invoke the *unlink* utility.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

file The pathname of an existing file.

STDIN

Not used.

INPUT FILES

Not used.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unlink*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5.

NAME

uucp ‡'system-to-system copy

SYNOPSIS

UU

```
uucp [−cCdfjmr] [−n user] source-file... destination-file
```

DESCRIPTION

The *uucp* utility shall copy files named by the *source-file* argument to the *destination-file* argument. The files named can be on local or remote systems.

The *uucp* utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used, and that only characters defined in the portable filename character set be used for naming files. The protocol for transfer of files is unspecified by POSIX.1-2017.

Typical implementations of this utility require a communications line configured to use XBD Chapter 11 (on page 199), but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

OPTIONS

The *uucp* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−c Do not copy local file to the spool directory for transfer to the remote machine (default).

−C Force the copy of local files to the spool directory for transfer.

−d Make all necessary directories for the file copy (default).

−f Do not make intermediate directories for the file copy.

−j Write the job identification string to standard output. This job identification can be used by *uustat* to obtain the status or terminate a job.

−m Send mail to the requester when the copy is completed.

−n *user* Notify *user* on the remote system that a file was sent.

−r Do not start the file transfer; just queue the job.

OPERANDS

The following operands shall be supported:

destination-file, *source-file*

A pathname of a file to be copied to, or from, respectively. Either name can be a pathname on the local machine, or can have the form:

```
system-name!pathname
```

where *system-name* is taken from a list of system names that *uucp* knows about. The destination *system-name* can also be a list of names such as:

```
system-name!system-name!...!system-name!pathname
```

in which case, an attempt is made to send the file via the specified route to the

112942 destination. Care should be taken to ensure that intermediate nodes in the route
112943 are willing to forward information.

112944 The shell pattern matching notation characters `'?'`, `'*'`, and `"[...]"` appearing
112945 in *pathname* shall be expanded on the appropriate system.

112946 Pathnames can be one of:

112947 1. An absolute pathname.

112948 2. A pathname preceded by *~user* where *user* is a login name on the specified
112949 system and is replaced by that user's login directory. Note that if an invalid
112950 login is specified, the default is to the public directory (called *PUBDIR*; the
112951 actual location of *PUBDIR* is implementation-defined).

112952 3. A pathname preceded by *~/destination* where *destination* is appended to
112953 *PUBDIR*.

112954 **Note:** This destination is treated as a filename unless more than one file is being
112955 transferred by this request or the destination is already a directory. To
112956 ensure that it is a directory, follow the destination with a `'/'`. For
112957 example, **~/dan/** as the destination makes the directory **PUBDIR/dan** if it
112958 does not exist and puts the requested files in that directory.

112959 4. Anything else shall be prefixed by the current directory.

112960 If the result is an erroneous pathname for the remote system, the copy shall fail. If
112961 the *destination-file* is a directory, the last part of the *source-file* name shall be used.

112962 The read, write, and execute permissions given by *uucp* are implementation-
112963 defined.

112964 **STDIN**

112965 Not used.

112966 **INPUT FILES**

112967 The files to be copied are regular files.

112968 **ENVIRONMENT VARIABLES**

112969 The following environment variables shall affect the execution of *uucp*:

112970 *LANG* Provide a default value for the internationalization variables that are unset or null.
112971 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
112972 variables used to determine the values of locale categories.)

112973 *LC_ALL* If set to a non-empty string value, override the values of all the other
112974 internationalization variables.

112975 *LC_COLLATE*
112976 Determine the locale for the behavior of ranges, equivalence classes, and multi-
112977 character collating elements within bracketed filename patterns.

112978 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
112979 characters (for example, single-byte as opposed to multi-byte characters in
112980 arguments and input files) and the behavior of character classes within bracketed
112981 filename patterns (for example, `"'[[:lower:]]*'"`).

112982 *LC_MESSAGES*
112983 Determine the locale that should be used to affect the format and contents of
112984 diagnostic messages written to standard error, and informative messages written
112985 to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files (which may be on other systems) are copies of the input files.

If **−m** is used, mail files are modified.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility is part of the UUCP Utilities option and need not be supported by all implementations.

The domain of remotely accessible files can (and for obvious security reasons usually should) be severely restricted.

Note that the `'!'` character in addresses has to be escaped when using *csh* as a command interpreter because of its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but may be used.

As noted above, shell metacharacters appearing in pathnames are expanded on the appropriate system. On an internationalized system, this is done under the control of local settings of *LC_COLLATE* and *LC_CTYPE*. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

The UN margin codes and associated shading are removed from the **−C**, **−f**, **−j**, **−n**, and **−r** options in response to The Open Group Base Resolution bwg2001-003.

Issue 7

SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

uudecode ‡'decode a binary file

SYNOPSIS

```
uudecode [−o outfile] [file]
```

DESCRIPTION

The *uudecode* utility shall read a file, or standard input if no file is specified, that includes data created by the *uuencode* utility. The *uudecode* utility shall scan the input file, searching for data compatible with one of the formats specified in *uuencode*, and attempt to create or overwrite the file described by the data (or overridden by the **−o** option). The pathname shall be contained in the data or specified by the **−o** option. The file access permission bits and contents for the file to be produced shall be contained in that data. The mode bits of the created file (other than standard output) shall be set from the file access permission bits contained in the data; that is, other attributes of the mode, including the file mode creation mask (see *umask*), shall not affect the file being produced. If either of the *op* characters '+' and '−' (see *chmod*) are specified in symbolic mode, the initial mode on which those operations are based is unspecified.

If the pathname of the file resolves to an existing file and the user does not have write permission on that file, *uudecode* shall terminate with an error. If the pathname of the file resolves to an existing file and the user has write permission on that file, the existing file shall be overwritten and, if possible, the mode bits of the file (other than standard output) shall be set as described above; if the mode bits cannot be set, *uudecode* shall not treat this as an error.

If the input data was produced by *uuencode* on a system with a different number of bits per byte than on the target system, the results of *uudecode* are unspecified.

OPTIONS

The *uudecode* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported by the implementation:

−o *outfile* A pathname of a file that shall be used instead of any pathname contained in the input data. Specifying an *outfile* option-argument of **/dev/stdout** shall indicate standard output.

OPERANDS

The following operand shall be supported:

file The pathname of a file containing the output of *uuencode*.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be files containing the output of *uuencode*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uudecode*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
If the file data header encoded by *uuencode* is − or **/dev/stdout**, or the **−o /dev/stdout** option overrides the file data, the standard output shall be in the same format as the file originally encoded by *uuencode*. Otherwise, the standard output shall not be used.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
The output file shall be in the same format as the file originally encoded by *uuencode*.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The user who is invoking *uudecode* must have write permission on any file being created.

The output of *uuencode* is essentially an encoded bit stream that is not cognizant of byte boundaries. It is possible that a 9-bit byte target machine can process input from an 8-bit source, if it is aware of the requirement, but the reverse is unlikely to be satisfying. Of course, the only data that is meaningful for such a transfer between architectures is generally character data.

EXAMPLES
None.

RATIONALE
Input files are not necessarily text files, as stated by an early proposal. Although the *uuencode* output is a text file, that output could have been wrapped within another file or mail message that is not a text file.

The **−o** option is not historical practice, but was added at the request of WG15 so that the user could override the target pathname without having to edit the input data itself.

In early drafts, the [**−o** *outfile*] option-argument allowed the use of − to mean standard output. The symbol − has only been used previously in POSIX.1-2017 as a standard input indicator. The standard developers did not wish to overload the meaning of − in this manner. The **/dev/stdout** concept exists on most modern systems. The **/dev/stdout** syntax does not refer to a new special file. It is just a magic cookie to specify standard output.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The **−o** *outfile* option is added, as specified in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/35 is applied, clarifying in the DESCRIPTION that the initial mode used if either of the *op* characters is '+' or '−' is unspecified.

Issue 7

The *uudecode* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0201 [635] is applied.

NAME

uuencode ‡'encode a binary file

SYNOPSIS

```
uuencode [-m] [file] decode_pathname
```

DESCRIPTION

The *uuencode* utility shall write an encoded version of the named input file, or standard input if no *file* is specified, to standard output. The output shall be encoded using one of the algorithms described in the STDOUT section and shall include the file access permission bits (in *chmod* octal or symbolic notation) of the input file and the *decode_pathname*, for re-creation of the file on another system that conforms to this volume of POSIX.1-2017.

OPTIONS

The *uuencode* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported by the implementation:

−m Encode the output using the MIME Base64 algorithm described in STDOUT. If **−m** is not specified, the historical algorithm described in STDOUT shall be used.

OPERANDS

The following operands shall be supported:

decode_pathname
: The pathname of the file into which the *uudecode* utility shall place the decoded file. Specifying a *decode_pathname* operand of **/dev/stdout** shall indicate that *uudecode* is to use standard output. If there are characters in *decode_pathname* that are not in the portable filename character set the results are unspecified.

file A pathname of the file to be encoded.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files can be files of any type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uuencode*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
: Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

uuencode Base64 Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:

`"begin-base64Δ%sΔ%s\n", <mode>, <decode_pathname>`

and ends with the line:

`"====\n"`

In both cases, the lines shall have no preceding or trailing <blank> characters.

The encoding process represents 24-bit groups of input bits as output strings of four encoded characters. Proceeding from left to right, a 24-bit input group shall be formed by concatenating three 8-bit input groups. Each 24-bit input group then shall be treated as four concatenated 6-bit groups, each of which shall be translated into a single digit in the Base64 alphabet. When encoding a bit stream via the Base64 encoding, the bit stream shall be presumed to be ordered with the most-significant bit first. That is, the first bit in the stream shall be the high-order bit in the first byte, and the eighth bit shall be the low-order bit in the first byte, and so on. Each 6-bit group is used as an index into an array of 64 printable characters, as shown in Table 4-22.

Table 4-22 uuencode Base64 Values

Value	Encoding	Value	Encoding	Value	Encoding	Value	Encoding
0	A	17	R	34	i	51	z
1	B	18	S	35	j	52	0
2	C	19	T	36	k	53	1
3	D	20	U	37	l	54	2
4	E	21	V	38	m	55	3
5	F	22	W	39	n	56	4
6	G	23	X	40	o	57	5
7	H	24	Y	41	p	58	6
8	I	25	Z	42	q	59	7
9	J	26	a	43	r	60	8
10	K	27	b	44	s	61	9
11	L	28	c	45	t	62	+
12	M	29	d	46	u	63	/
13	N	30	e	47	v		
14	O	31	f	48	w	(pad)	=
15	P	32	g	49	x		
16	Q	33	h	50	y		

The character referenced by the index shall be placed in the output string.

The output stream (encoded bytes) shall be represented in lines of no more than 76 characters each. All line breaks or other characters not found in the table shall be ignored by decoding software (see *uudecode*).

Special processing shall be performed if fewer than 24 bits are available at the end of a message or encapsulated part of a message. A full encoding quantum shall always be completed at the

113225 end of a message. When fewer than 24 input bits are available in an input group, zero bits shall
113226 be added (on the right) to form an integral number of 6-bit groups. Output character positions
113227 that are not required to represent actual input data shall be set to the character `'='`. Since all
113228 Base64 input is an integral number of octets, only the following cases can arise:

113229 1. The final quantum of encoding input is an integral multiple of 24 bits; here, the final unit
113230 of encoded output shall be an integral multiple of 4 characters with no `'='` padding.

113231 2. The final quantum of encoding input is exactly 16 bits; here, the final unit of encoded
113232 output shall be three characters followed by one `'='` padding character.

113233 3. The final quantum of encoding input is exactly 8 bits; here, the final unit of encoded
113234 output shall be two characters followed by two `'='` padding characters.

113235 A terminating `"===="` evaluates to nothing and denotes the end of the encoded data.

113236 **uuencode Historical Algorithm**

113237 The standard output shall be a text file (encoded in the character set of the current locale) that
113238 begins with the line:

113239 `"begin␣%s␣%s\n"` *<mode>*, *<decode_pathname>*

113240 and ends with the line:

113241 `"end\n"`

113242 In both cases, the lines shall have no preceding or trailing <blank> characters.

113243 The algorithm that shall be used for lines in between **begin** and **end** takes three octets as input
113244 and writes four characters of output by splitting the input at six-bit intervals into four octets,
113245 containing data in the lower six bits only. These octets shall be converted to characters by adding
113246 a value of 0x20 to each octet, so that each octet is in the range [0x20,0x5f], and then it shall be
113247 assumed to represent a printable character in the ISO/IEC 646:1991 standard encoded character
113248 set. It then shall be translated into the corresponding character codes for the codeset in use in the
113249 current locale. (For example, the octet 0x41, representing `'A'`, would be translated to `'A'` in the
113250 current codeset, such as 0xc1 if it were EBCDIC.)

113251 Where the bits of two octets are combined, the least significant bits of the first octet shall be
113252 shifted left and combined with the most significant bits of the second octet shifted right. Thus
113253 the three octets *A*, *B*, *C* shall be converted into the four octets:

```
113254 0x20 + (( A >> 2                     ) & 0x3F)
113255 0x20 + (((A << 4) | ((B >> 4) & 0xF)) & 0x3F)
113256 0x20 + (((B << 2) | ((C >> 6) & 0x3)) & 0x3F)
113257 0x20 + (( C                          ) & 0x3F)
```

113258 These octets then shall be translated into the local character set.

113259 Each encoded line contains a length character, equal to the number of characters to be decoded
113260 plus 0x20 translated to the local character set as described above, followed by the encoded
113261 characters. The maximum number of octets to be encoded on each line shall be 45.

113262 **STDERR**

113263 The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The file is expanded by 35 percent (each three octets become four, plus control information) causing it to take longer to transmit.

Since this utility is intended to create files to be used for data interchange between systems with possibly different codesets, and to represent binary data as a text file, the ISO/IEC 646:1991 standard was chosen for a midpoint in the algorithm as a known reference point. The output from *uuencode* is a text file on the local system. If the output were in the ISO/IEC 646:1991 standard codeset, it might not be a text file (at least because the <newline> characters might not match), and the goal of creating a text file would be defeated. If this text file was then carried to another machine with the same codeset, it would be perfectly compatible with that system's *uudecode*. If it was transmitted over a mail system or sent to a machine with a different codeset, it is assumed that, as for every other text file, some translation mechanism would convert it (by the time it reached a user on the other system) into an appropriate codeset. This translation only makes sense from the local codeset, not if the file has been put into a ISO/IEC 646:1991 standard representation first. Similarly, files processed by *uuencode* can be placed in *pax* archives, intermixed with other text files in the same codeset.

EXAMPLES

None.

RATIONALE

A new algorithm was added at the request of the international community to parallel work in RFC 2045 (MIME). As with the historical *uuencode* format, the Base64 Content-Transfer-Encoding is designed to represent arbitrary sequences of octets in a form that is not humanly readable. A 65-character subset of the ISO/IEC 646:1991 standard is used, enabling 6 bits to be represented per printable character. (The extra 65th character, `'='`, is used to signify a special processing function.)

This subset has the important property that it is represented identically in all versions of the ISO/IEC 646:1991 standard, including US ASCII, and all characters in the subset are also represented identically in all versions of EBCDIC. The historical *uuencode* algorithm does not share this property, which is the reason that a second algorithm was added to the ISO POSIX-2 standard.

The string `"===="` was used for the termination instead of the end used in the original format because the latter is a string that could be valid encoded input.

In an early draft, the **−m** option was named **−b** (for Base64), but it was renamed to reflect its relationship to the RFC 2045. A **−u** was also present to invoke the default algorithm, but since this was not historical practice, it was omitted as being unnecessary.

See the RATIONALE section in *uudecode* for the derivation of the **/dev/stdout** symbol.

FUTURE DIRECTIONS

None.

chmod, *mailx*, *uudecode*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The Base64 algorithm and the ability to output to **/dev/stdout** are added as specified in the IEEE P1003.2b draft standard.

Issue 7

The *uuencode* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

uustat — uucp status enquiry and job control

SYNOPSIS

UU

```
uustat [−q|−k jobid|−r jobid]
uustat [−s system] [−u user]
```

DESCRIPTION

The *uustat* utility shall display the status of, or cancel, previously specified *uucp* requests, or provide general status on *uucp* connections to other systems.

When no options are given, *uustat* shall write to standard output the status of all *uucp* requests issued by the current user.

Typical implementations of this utility require a communications line configured to use XBD Chapter 11 (on page 199), but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

OPTIONS

The *uustat* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−q Write the jobs queued for each machine.

−k *jobid* Kill the *uucp* request whose job identification is *jobid*. The application shall ensure that the killed *uucp* request belongs to the person invoking *uustat* unless that user has appropriate privileges.

−r *jobid* Rejuvenate *jobid*. The files associated with *jobid* are touched so that their modification time is set to the current time. This prevents the cleanup program from deleting the job until the jobs modification time reaches the limit imposed by the program.

−s *system* Write the status of all *uucp* requests for remote system *system*.

−u *user* Write the status of all *uucp* requests issued by *user*.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uustat*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

113365 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
113366 characters (for example, single-byte as opposed to multi-byte characters in
113367 arguments).

113368 *LC_MESSAGES*
113369 Determine the locale that should be used to affect the format and contents of
113370 diagnostic messages written to standard error, and informative messages written
113371 to standard output.

113372 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

113373 **ASYNCHRONOUS EVENTS**
113374 Default.

113375 **STDOUT**
113376 The standard output shall consist of information about each job selected, in an unspecified
113377 format. The information shall include at least the job ID, the user ID or name, and the remote
113378 system name.

113379 **STDERR**
113380 The standard error shall be used only for diagnostic messages.

113381 **OUTPUT FILES**
113382 None.

113383 **EXTENDED DESCRIPTION**
113384 None.

113385 **EXIT STATUS**
113386 The following exit values shall be returned:

113387 0 Successful completion.

113388 >0 An error occurred.

113389 **CONSEQUENCES OF ERRORS**
113390 Default.

113391 **APPLICATION USAGE**
113392 This utility is part of the UUCP Utilities option and need not be supported by all
113393 implementations.

113394 **EXAMPLES**
113395 None.

113396 **RATIONALE**
113397 None.

113398 **FUTURE DIRECTIONS**
113399 None.

113400 **SEE ALSO**
113401 *uucp*

113403 **CHANGE HISTORY**
113404 First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

The UN margin code and associated shading are removed from the **−q** option in response to The Open Group Base Resolution bwg2001-003.

Issue 7

SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

uux — remote command execution

SYNOPSIS

UU

```
uux [-jnp] command-string
```

DESCRIPTION

The *uux* utility shall gather zero or more files from various systems, execute a shell pipeline (see Section 2.9, on page 2365) on a specified system, and then send the standard output of the command to a file on a specified system. Only the first command of a pipeline can have a *system-name*! prefix. All other commands in the pipeline shall be executed on the system of the first command.

The following restrictions are applicable to the shell pipeline processed by *uux*:

In gathering files from different systems, pathname expansion shall not be performed by *uux*. Thus, a request such as:

```
uux "c99 remsys!~/*.c"
```

would attempt to copy the file named literally ***.c** to the local system.

The redirection operators `">>"`, `"<<"`, `">|"`, and `">&"` shall not be accepted. Any use of these redirection operators shall cause this utility to write an error message describing the problem and exit with a non-zero exit status.

The reserved word **!** cannot be used at the head of the pipeline to modify the exit status. (See the *command-string* operand description below.)

Alias substitution shall not be performed.

A filename can be specified as for *uucp*; it can be an absolute pathname, a pathname preceded by *~name* (which is replaced by the corresponding login directory), a pathname specified as *~/dest* (*dest* is prefixed by the public directory called *PUBDIR*; the actual location of *PUBDIR* is implementation-defined), or a simple filename (which is prefixed by *uux* with the current directory). See *uucp* for the details.

The execution of commands on remote systems shall take place in an execution directory known to the *uucp* system. All files required for the execution shall be put into this directory unless they already reside on that machine. Therefore, the application shall ensure that non-local filenames (without path or machine reference) are unique within the *uux* request.

The *uux* utility shall attempt to get all files to the execution system. For files that are output files, the application shall ensure that the filename is escaped using parentheses.

The remote system shall notify the user by mail if the requested command on the remote system was disallowed or the files were not accessible. This notification can be turned off by the **–n** option.

Typical implementations of this utility require a communications line configured to use XBD Chapter 11 (on page 199), but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

The *uux* utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used

and that only characters defined in the portable filename character set be used for naming files.

OPTIONS

The *uux* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−j Write the job identification string to standard output. This job identification can be used by *uustat* to obtain the status or terminate a job.

−n Do not notify the user if the command fails.

−p Make the standard input to *uux* the standard input to the *command-string*.

OPERANDS

The following operand shall be supported:

command-string
A string made up of one or more arguments that are similar to normal command arguments, except that the command and any filenames can be prefixed by *system-name*!. A null *system-name* shall be interpreted as the local system.

STDIN

The standard input shall not be used unless the `'-'` or **−p** option is specified; in those cases, the standard input shall be made the standard input of the *command-string*.

INPUT FILES

Input files shall be selected according to the contents of *command-string*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uux*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall not be used unless the **−j** option is specified; in that case, the job identification string shall be written to standard output in the following format:

`"%s\n", <jobid>`

113496 **STDERR**

113497 The standard error shall be used only for diagnostic messages.

113498 **OUTPUT FILES**

113499 Output files shall be created or written, or both, according to the contents of *command-string*.

113500 If **−n** is not used, mail files shall be modified following any command or file-access failures on
113501 the remote system.

113502 **EXTENDED DESCRIPTION**

113503 None.

113504 **EXIT STATUS**

113505 The following exit values shall be returned:

113506 0 Successful completion.

113507 >0 An error occurred.

113508 **CONSEQUENCES OF ERRORS**

113509 Default.

113510 **APPLICATION USAGE**

113511 This utility is part of the UUCP Utilities option and need not be supported by all
113512 implementations.

113513 Note that, for security reasons, many installations limit the list of commands executable on
113514 behalf of an incoming request from *uux*. Many sites permit little more than the receipt of mail
113515 via *uux*.

113516 Any characters special to the command interpreter should be quoted either by quoting the entire
113517 *command-string* or quoting the special characters as individual arguments.

113518 As noted in *uucp*, shell pattern matching notation characters appearing in pathnames are
113519 expanded on the appropriate local system. This is done under the control of local settings of
113520 *LC_COLLATE* and *LC_CTYPE*. Thus, care should be taken when using bracketed filename
113521 patterns, as collation and typing rules may vary from one system to another. Also be aware that
113522 certain types of expression (that is, equivalence classes, character classes, and collating symbols)
113523 need not be supported on non-internationalized systems.

113524 **EXAMPLES**

113525 1. The following command gets **file1** from system **a** and **file2** from system **b**, executes *diff* on
113526 the local system, and puts the results in **file.diff** in the local *PUBDIR* directory. (*PUBDIR*
113527 is the *uucp* public directory on the local system.)

113528 ```
uux "!diff a!/usr/file1 b!/a4/file2 >!~/file.diff"
```

113529 2. The following command fails because *uux* places all files copied to a system in the same
113530 working directory. Although the files **xyz** are from two different systems, their filenames
113531 are the same and conflict.

113532 ```
uux "!diff a!/usr1/xyz b!/usr2/xyz >!~/xyz.diff"
```

113533 3. The following command succeeds (assuming *diff* is permitted on system **a**) because the
113534 file local to system **a** is not copied to the working directory, and hence does not conflict
113535 with the file from system **c**.

113536 ```
uux "a!diff a!/usr/xyz c!/usr/xyz >!~/xyz.diff"
```

  
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent SYNOPSIS is removed.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

The UN margin code and associated shading are removed from the **–j** option in response to The Open Group Base Resolution bwg2001-003.

Issue 7

SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

NAME

val ‡'validate SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI
```
val -

val [-s] [-m name] [-r SID] [-y type] file...
```

DESCRIPTION

The *val* utility shall determine whether the specified *file* is an SCCS file meeting the characteristics specified by the options.

OPTIONS

The *val* utility shall conform to XBD Section 12.2 (on page 216), except that the usage of the '-' operand is not strictly as intended by the guidelines (that is, reading options and operands from standard input).

The following options shall be supported:

-m *name* Specify a *name*, which is compared with the SCCS %**M**% keyword in *file*; see *get*.

-r *SID* Specify a *SID* (SCCS Identification String), an SCCS delta number. A check shall be made to determine whether the *SID* is ambiguous (for example, **-r 1** is ambiguous because it physically does not exist but implies 1.1, 1.2, and so on, which may exist) or invalid (for example, **-r 1.0** or **-r 1.1.0** are invalid because neither case can exist as a valid delta number). If the *SID* is valid and not ambiguous, a check shall be made to determine whether it actually exists.

-s Silence the diagnostic message normally written to standard output for any error that is detected while processing each named file on a given command line.

-y *type* Specify a *type*, which shall be compared with the SCCS %**Y**% keyword in *file*; see *get*.

OPERANDS

The following operands shall be supported:

file A pathname of an existing SCCS file. If exactly one *file* operand appears, and it is '-', the standard input shall be read: each line shall be independently processed as if it were a command line argument list. (However, the line is not subjected to any of the shell word expansions, such as parameter expansion or quote removal.)

STDIN

The standard input shall be a text file used only when the *file* operand is specified as '-'.

INPUT FILES

Any SCCS files processed shall be files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *val*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

113594 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
113595 characters (for example, single-byte as opposed to multi-byte characters in
113596 arguments and input files).

113597 *LC_MESSAGES*
113598 Determine the locale that should be used to affect the format and contents of
113599 diagnostic messages written to standard error, and informative messages written
113600 to standard output.

113601 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

113602 **ASYNCHRONOUS EVENTS**
113603 Default.

113604 **STDOUT**
113605 The standard output shall consist of informative messages about either:

113606 1. Each file processed

113607 2. Each command line read from standard input

113608 If the standard input is not used, for each *file* operand yielding a discrepancy, the output line
113609 shall have the following format:

113610 `"%s: %s\n", <pathname>, <unspecified string>`

113611 If the standard input is used, for each input line yielding a discrepancy, the output shall have the
113612 following format:

113613 `"%s\n\n %s: %s\n", <input>, <pathname>, <unspecified string>`

113614 where <*input*> is the input line minus its terminating <newline>.

113615 **STDERR**
113616 Not used.

113617 **OUTPUT FILES**
113618 None.

113619 **EXTENDED DESCRIPTION**
113620 None.

113621 **EXIT STATUS**
113622 The 8-bit code returned by *val* shall be a disjunction of the possible errors; that is, it can be
113623 interpreted as a bit string where set bits are interpreted as follows:

113624 0x80 = Missing file argument.
113625 0x40 = Unknown or duplicate option.
113626 0x20 = Corrupted SCCS file.
113627 0x10 = Cannot open file or file not SCCS.
113628 0x08 = *SID* is invalid or ambiguous.
113629 0x04 = *SID* does not exist.
113630 0x02 = %**Y**%, **−y** mismatch.
113631 0x01 = %**M**%, **−m** mismatch.

113632 Note that *val* can process two or more files on a given command line and can process multiple
113633 command lines (when reading the standard input). In these cases an aggregate code shall be
113634 returned: a logical OR of the codes generated for each command line and file processed.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since the *val* exit status sets the 0x80 bit, shell applications checking `"$?"` cannot tell if it terminated due to a missing file argument or receipt of a signal.

EXAMPLES

In a directory with three SCCS files—**s.x** (of **t** type ``text''), **s.y**, and **s.z** (a corrupted file)—the following command could produce the output shown:

```
val - <<EOF
-y source s.x
-m y s.y
s.z
EOF
-y source s.x
```

```
    s.x: %Y%, -y mismatch
s.z
```

```
    s.z: corrupted SCCS file
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The Open Group Corrigendum U025/4 is applied, correcting a typographical error in the EXIT STATUS.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0147 [416] and XCU/TC1-2008/0148 [416] are applied.

NAME

vi — screen-oriented (visual) display editor

SYNOPSIS

UP

```
vi [−rR] [−c command] [−t tagstring] [−w size] [file...]
```

DESCRIPTION

This utility shall be provided on systems that both support the User Portability Utilities option and define the POSIX2_CHAR_TERM symbol. On other systems it is optional.

The *vi* (visual) utility is a screen-oriented text editor. Only the open and visual modes of the editor are described in POSIX.1-2017; see the line editor *ex* for additional editing capabilities used in *vi*. The user can switch back and forth between *vi* and *ex* and execute *ex* commands from within *vi*.

This reference page uses the term *edit buffer* to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.

When using *vi*, the terminal screen acts as a window into the editing buffer. Changes made to the editing buffer shall be reflected in the screen display; the position of the cursor on the screen shall indicate the position within the editing buffer.

Certain terminals do not have all the capabilities necessary to support the complete *vi* definition. When these commands cannot be supported on such terminals, this condition shall not produce an error message such as ``not an editor command'' or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of POSIX.1-2017 or report an error describing the terminal-related deficiency.

OPTIONS

The *vi* utility shall conform to XBD Section 12.2 (on page 216), except that `'+'` may be recognized as an option delimiter as well as `'−'`.

The following options shall be supported:

−c *command* See the *ex* command description of the **−c** option.

−r See the *ex* command description of the **−r** option.

−R See the *ex* command description of the **−R** option.

−t *tagstring* See the *ex* command description of the **−t** option.

−w *size* See the *ex* command description of the **−w** option.

OPERANDS

See the OPERANDS section of the *ex* command for a description of the operands supported by the *vi* command.

STDIN

If standard input is not a terminal device, the results are undefined. The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section.

If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

INPUT FILES

See the INPUT FILES section of the *ex* command for a description of the input files supported by the *vi* command.

ENVIRONMENT VARIABLES

See the ENVIRONMENT VARIABLES section of the *ex* command for the environment variables that affect the execution of the *vi* command.

ASYNCHRONOUS EVENTS

See the ASYNCHRONOUS EVENTS section of the *ex* for the asynchronous events that affect the execution of the *vi* command.

STDOUT

If standard output is not a terminal device, undefined results occur.

Standard output may be used for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR

If standard output is not a terminal device, undefined results occur.

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

See the OUTPUT FILES section of the *ex* command for a description of the output files supported by the *vi* command.

EXTENDED DESCRIPTION

If the terminal does not have the capabilities necessary to support an unspecified portion of the *vi* definition, implementations shall start initially in *ex* mode or open mode. Otherwise, after initialization, *vi* shall be in command mode; text input mode can be entered by one of several commands used to insert or change text. In text input mode, <ESC> can be used to return to command mode; other uses of <ESC> are described later in this section; see Terminate Command or Input Mode (on page 3385).

Initialization in ex and vi

See Initialization in ex and vi (on page 2701) for a description of *ex* and *vi* initialization for the *vi* utility.

Command Descriptions in vi

The following symbols are used in this reference page to represent arguments to commands.

buffer See the description of *buffer* in the EXTENDED DESCRIPTION section of the *ex* utility; see Command Descriptions in ex (on page 2710).

In open and visual mode, when a command synopsis shows both [*buffer*] and [*count*] preceding the command name, they can be specified in either order.

count A positive integer used as an optional argument to most commands, either to give a repeat count or as a size. This argument is optional and shall default to 1 unless otherwise specified.

The Synopsis lines for the *vi* commands <control>-G, <control>-L, <control>-R, <control>-], **%**, **&**, **^**, **D**, **m**, **M**, **Q**, **u**, **U**, and **ZZ** do not have *count* as an optional argument. Regardless, it shall not be an error to specify a *count* to these commands, and any specified *count* shall be ignored.

motion An optional trailing argument used by the **!**, **<**, **>**, **c**, **d**, and **y** commands, which is used to indicate the region of text that shall be affected by the command. The motion can be either one of the command characters repeated or one of several other *vi* commands (listed in the following table). Each of the applicable commands specifies the region of text matched by repeating the command; each command that can be used as a motion command specifies the region of text it affects.

Commands that take *motion* arguments operate on either lines or characters, depending on the circumstances. When operating on lines, all lines that fall partially or wholly within the text region specified for the command shall be affected. When operating on characters, only the exact characters in the specified text region shall be affected. Each motion command specifies this individually.

When commands that may be motion commands are not used as motion commands, they shall set the current position to the current line and column as specified.

The following commands shall be valid cursor motion commands:

<apostrophe>	(	-	j	H
<carriage-return>	)	$	k	L
<comma>	[[	%	l	M
<control>-H	]]	_	n	N
<control>-N	{	;	t	T
<control>-P	}	?	w	W
<grave-accent>	^	b	B	
<newline>	+	e	E	
<space>	|	f	F	
<zero>	/	h	G	

Any *count* that is specified to a command that has an associated motion command shall be applied to the motion command. If a *count* is applied to both the command and its associated motion command, the effect shall be multiplicative.

The following symbols are used in this section to specify locations in the edit buffer:

current character
The character that is currently indicated by the cursor.

end of a line
The point located between the last non-<newline> (if any) and the terminating <newline> of a line. For an empty line, this location coincides with the beginning of the line.

end of the edit buffer
The location corresponding to the end of the last line in the edit buffer.

The following symbols are used in this section to specify command actions:

bigword In the POSIX locale, *vi* shall recognize four kinds of *bigwords*:

1. A maximal sequence of non-<blank> characters preceded and followed by <blank> characters or the beginning or end of a line or the edit buffer
2. One or more sequential blank lines
3. The first character in the edit buffer

4. The last non-<newline> in the edit buffer

word In the POSIX locale, *vi* shall recognize five kinds of words:

1. A maximal sequence of letters, digits, and underscores, delimited at both ends by:
   - ‡ hCacters other than letters, digits, or underscores
   - ‡ hélbeginning or end of a line
   - ‡ hélbeginning or end of the edit buffer
2. A maximal sequence of characters other than letters, digits, underscores, or <blank> characters, delimited at both ends by:
   - ‡ leAter, digit, underscore
   - ‡ blank> characters
   - ‡ hélbeginning or end of a line
   - ‡ hélbeginning or end of the edit buffer
3. One or more sequential blank lines
4. The first character in the edit buffer
5. The last non-<newline> in the edit buffer

section boundary

A *section boundary* is one of the following:

1. A line whose first character is a <form-feed>
2. A line whose first character is an open curly brace (`'{'`)
3. A line whose first character is a <period> and whose second and third characters match a two-character pair in the **sections** edit option (see *ex*)
4. A line whose first character is a <period> and whose only other character matches the first character of a two-character pair in the **sections** edit option, where the second character of the two-character pair is a <space>
5. The first line of the edit buffer
6. The last line of the edit buffer if the last line of the edit buffer is empty or if it is a]] or } command; otherwise, the last non-<newline> of the last line of the edit buffer

paragraph boundary

A *paragraph boundary* is one of the following:

1. A section boundary
2. A line whose first character is a <period> and whose second and third characters match a two-character pair in the **paragraphs** edit option (see *ex*)
3. A line whose first character is a <period> and whose only other character matches the first character of a two-character pair in the *paragraphs* edit option, where the second character of the two-character pair is a <space>

4. One or more sequential blank lines

remembered search direction
: See the description of *remembered search direction* in *ex*.

sentence boundary
: A *sentence boundary* is one of the following:

1. A paragraph boundary
2. The first non-<blank> that occurs after a paragraph boundary
3. The first non-<blank> that occurs after a <period> (`'.'`), <exclamation-mark> (`'!'`), or <question-mark> (`'?'`), followed by two <space> characters or the end of a line; any number of closing parenthesis (`')'`), closing brackets (`']'`), double-quote (`'"'`), or single-quote (<apostrophe>) characters can appear between the punctuation mark and the two <space> characters or end-of-line

In the remainder of the description of the *vi* utility, the term ``buffer line'' refers to a line in the edit buffer and the term ``display line'' refers to the line or lines on the display screen used to display one buffer line. The term ``current line'' refers to a specific ``buffer line''.

If there are display lines on the screen for which there are no corresponding buffer lines because they correspond to lines that would be after the end of the file, they shall be displayed as a single <tilde> (`'~'`) character, plus the terminating <newline>.

The last line of the screen shall be used to report errors or display informational messages. It shall also be used to display the input for ``line-oriented commands'' (**/**, **?**, **:**, and **!**). When a line-oriented command is executed, the editor shall enter text input mode on the last line on the screen, using the respective command characters as prompt characters. (In the case of the **!** command, the associated motion shall be entered by the user before the editor enters text input mode.) The line entered by the user shall be terminated by a <newline>, a non-<control>-V-escaped <carriage-return>, or unescaped <ESC>. It is unspecified if more characters than require a display width minus one column number of screen columns can be entered.

If any command is executed that overwrites a portion of the screen other than the last line of the screen (for example, the *ex* **suspend** or **!** commands), other than the *ex* **shell** command, the user shall be prompted for a character before the screen is refreshed and the edit session continued.

<tab> characters shall take up the number of columns on the screen set by the **tabstop** edit option (see *ex*), unless there are less than that number of columns before the display margin that will cause the displayed line to be folded; in this case, they shall only take up the number of columns up to that boundary.

The cursor shall be placed on the current line and relative to the current column as specified by each command described in the following sections.

In open mode, if the current line is not already displayed, then it shall be displayed.

In visual mode, if the current line is not displayed, then the lines that are displayed shall be expanded, scrolled, or redrawn to cause an unspecified portion of the current line to be displayed. If the screen is redrawn, no more than the number of display lines specified by the value of the **window** edit option shall be displayed (unless the current line cannot be completely displayed in the number of display lines specified by the **window** edit option) and the current line shall be positioned as close to the center of the displayed lines as possible (within the constraints imposed by the distance of the line from the beginning or end of the edit buffer). If the current line is before the first line in the display and the screen is scrolled, an unspecified

113874 portion of the current line shall be placed on the first line of the display. If the current line is after
113875 the last line in the display and the screen is scrolled, an unspecified portion of the current line
113876 shall be placed on the last line of the display.

113877 In visual mode, if a line from the edit buffer (other than the current line) does not entirely fit into
113878 the lines at the bottom of the display that are available for its presentation, the editor may choose
113879 not to display any portion of the line. The lines of the display that do not contain text from the
113880 edit buffer for this reason shall each consist of a single '@' character.

113881 In visual mode, the editor may choose for unspecified reasons to not update lines in the display
113882 to correspond to the underlying edit buffer text. The lines of the display that do not correctly
113883 correspond to text from the edit buffer for this reason shall consist of a single '@' character (plus
113884 the terminating <newline>), and the <control>-R command shall cause the editor to update the
113885 screen to correctly represent the edit buffer.

113886 Open and visual mode commands that set the current column set it to a column position in the
113887 display, and not a character position in the line. In this case, however, the column position in the
113888 display shall be calculated for an infinite width display; for example, the column related to a
113889 character that is part of a line that has been folded onto additional screen lines will be offset from
113890 the display line column where the buffer line begins, not from the beginning of a particular
113891 display line.

113892 The display cursor column in the display is based on the value of the current column, as follows,
113893 with each rule applied in turn:

113894 1. If the current column is after the last display line column used by the displayed line, the
113895 display cursor column shall be set to the last display line column occupied by the last
113896 non-<newline> in the current line; otherwise, the display cursor column shall be set to the
113897 current column.

113898 2. If the character of which some portion is displayed in the display line column specified by
113899 the display cursor column requires more than a single display line column:

113900 a. If in text input mode, the display cursor column shall be adjusted to the first
113901 display line column in which any portion of that character is displayed.

113902 b. Otherwise, the display cursor column shall be adjusted to the last display line
113903 column in which any portion of that character is displayed.

113904 The current column shall not be changed by these adjustments to the display cursor column.

113905 If an error occurs during the parsing or execution of a *vi* command:

113906 The terminal shall be alerted. Execution of the *vi* command shall stop, and the cursor (for
113907 example, the current line and column) shall not be further modified.

113908 Unless otherwise specified by the following command sections, it is unspecified whether
113909 an informational message shall be displayed.

113910 Any partially entered *vi* command shall be discarded.

113911 If the *vi* command resulted from a **map** expansion, all characters from that **map** expansion
113912 shall be discarded, except as otherwise specified by the **map** command (see *ex*).

113913 If the *vi* command resulted from the execution of a buffer, no further commands caused by
113914 the execution of the buffer shall be executed.

113915 **Page Backwards**

113916 *Synopsis*: **[***count***]** <control>-B

113917 If in open mode, the <control>-B command shall behave identically to the **z** command.
113918 Otherwise, if the current line is the first line of the edit buffer, it shall be an error.

113919 If the **window** edit option is less than 3, display a screen where the last line of the display shall
113920 be some portion of:

113921 (*current first line*) −1

113922 otherwise, display a screen where the first line of the display shall be some portion of:

113923 (*current first line*) − *count* x ((window edit option) −2)

113924 If this calculation would result in a line that is before the first line of the edit buffer, the first line
113925 of the display shall display some portion of the first line of the edit buffer.

113926 *Current line*: If no lines from the previous display remain on the screen, set to the last line of the
113927 display; otherwise, set to (*line* – the number of new lines displayed on this screen).

113928 *Current column*: Set to non-<blank>.

113929 **Scroll Forward**

113930 *Synopsis*: **[***count***]** <control>-D

113931 If the current line is the last line of the edit buffer, it shall be an error.

113932 If no *count* is specified, *count* shall default to the *count* associated with the previous <control>-D
113933 or <control>-U command. If there was no previous <control>-D or <control>-U command, *count*
113934 shall default to the value of the **scroll** edit option.

113935 If in open mode, write lines starting with the line after the current line, until *count* lines or the
113936 last line of the file have been written.

113937 *Current line*: If the current line + *count* is past the last line of the edit buffer, set to the last line of
113938 the edit buffer; otherwise, set to the current line + *count*.

113939 *Current column*: Set to non-<blank>.

113940 **Scroll Forward by Line**

113941 *Synopsis*: **[***count***]** <control>-E

113942 Display the line count lines after the last line currently displayed.

113943 If the last line of the edit buffer is displayed, it shall be an error. If there is no line *count* lines
113944 after the last line currently displayed, the last line of the display shall display some portion of
113945 the last line of the edit buffer.

113946 *Current line*: Unchanged if the previous current character is displayed; otherwise, set to the first
113947 line displayed.

113948 *Current column*: Unchanged.

113949 **Page Forward**

113950 *Synopsis*: **[***count***]** <control>-F

113951 If in open mode, the <control>-F command shall behave identically to the **z** command.
113952 Otherwise, if the current line is the last line of the edit buffer, it shall be an error.

113953 If the **window** edit option is less than 3, display a screen where the first line of the display shall
113954 be some portion of:

113955 (*current last line*) +1

113956 otherwise, display a screen where the first line of the display shall be some portion of:

113957 (*current first line*) + *count* x ((window edit option) −2)

113958 If this calculation would result in a line that is after the last line of the edit buffer, the last line of
113959 the display shall display some portion of the last line of the edit buffer.

113960 *Current line*: If no lines from the previous display remain on the screen, set to the first line of the
113961 display; otherwise, set to (*line* + the number of new lines displayed on this screen).

113962 *Current column*: Set to non-<blank>.

113963 **Display Information**

113964 *Synopsis*: <control>-G

113965 This command shall be equivalent to the *ex* **file** command.

113966 **Move Cursor Backwards**

113967 *Synopsis*: **[***count***]** <control>-H
113968 **[***count***]** h
113969 the current *erase* character (see stty)

113970 If there are no characters before the current character on the current line, it shall be an error. If
113971 there are less than *count* previous characters on the current line, *count* shall be adjusted to the
113972 number of previous characters on the line.

113973 If used as a motion command:

113974 1. The text region shall be from the character before the starting cursor up to and including
113975 the *count*th character before the starting cursor.

113976 2. Any text copied to a buffer shall be in character mode.

113977 If not used as a motion command:

113978 *Current line*: Unchanged.

113979 *Current column*: Set to (*column* − the number of columns occupied by *count* characters ending
113980 with the previous current column).

113981 **Move Down**

113982 *Synopsis*: **[***count***]** <newline>
113983 **[***count***]** <control>-J
113984 **[***count***]** <control>-M
113985 **[***count***]** <control>-N
113986 **[***count***]** j
113987 **[***count***]** <carriage-return>
113988 **[***count***]** +

113989 If there are less than *count* lines after the current line in the edit buffer, it shall be an error.

113990 If used as a motion command:

113991 1. The text region shall include the starting line and the next *count* – 1 lines.

113992 2. Any text copied to a buffer shall be in line mode.

113993 If not used as a motion command:

113994 *Current line*: Set to *current line*+ *count*.

113995 *Current column*: Set to non-<blank> for the <carriage-return>, <control>-M, and **+** commands;
113996 otherwise, unchanged.

113997 **Clear and Redisplay**

113998 *Synopsis*: <control>-L

113999 If in open mode, clear the screen and redisplay the current line. Otherwise, clear and redisplay
114000 the screen.

114001 *Current line*: Unchanged.

114002 *Current column*: Unchanged.

114003 **Move Up**

114004 *Synopsis*: **[***count***]** <control>-P
114005 **[***count***]** k
114006 **[***count***]** −

114007 If there are less than *count* lines before the current line in the edit buffer, it shall be an error.

114008 If used as a motion command:

114009 1. The text region shall include the starting line and the previous *count* lines.

114010 2. Any text copied to a buffer shall be in line mode.

114011 If not used as a motion command:

114012 *Current line*: Set to *current line* – *count*.

114013 *Current column*: Set to non-<blank> for the – command; otherwise, unchanged.

114014 **Redraw Screen**

114015 *Synopsis*: `<control>-R`

114016 If any lines have been deleted from the display screen and flagged as deleted on the terminal
114017 using the @ convention (see the beginning of the EXTENDED DESCRIPTION section), they shall
114018 be redisplayed to match the contents of the edit buffer.

114019 It is unspecified whether lines flagged with @ because they do not fit on the terminal display
114020 shall be affected.

114021 *Current line*: Unchanged.

114022 *Current column*: Unchanged.

114023 **Scroll Backward**

114024 *Synopsis*: **[***count***]** `<control>-U`

114025 If the current line is the first line of the edit buffer, it shall be an error.

114026 If no *count* is specified, *count* shall default to the *count* associated with the previous <control>-D
114027 or <control>-U command. If there was no previous <control>-D or <control>-U command, *count*
114028 shall default to the value of the **scroll** edit option.

114029 *Current line*: If *count* is greater than the current line, set to 1; otherwise, set to the current line –
114030 *count*.

114031 *Current column*: Set to non-<blank>.

114032 **Scroll Backward by Line**

114033 *Synopsis*: **[***count***]** `<control>-Y`

114034 Display the line *count* lines before the first line currently displayed.

114035 If the current line is the first line of the edit buffer, it shall be an error. If this calculation would
114036 result in a line that is before the first line of the edit buffer, the first line of the display shall
114037 display some portion of the first line of the edit buffer.

114038 *Current line*: Unchanged if the previous current character is displayed; otherwise, set to the first
114039 line displayed.

114040 *Current column*: Unchanged.

114041 **Edit the Alternate File**

114042 *Synopsis*: `<control>-^`

114043 This command shall be equivalent to the *ex* **edit** command, with the alternate pathname as its
114044 argument.

114045 **Terminate Command or Input Mode**

114046 *Synopsis*: `<ESC>`

114047 If a partial *vi* command (as defined by at least one, non-*count* character) has been entered,
114048 discard the *count* and the command character(s).

114049 Otherwise, if no command characters have been entered, and the <ESC> was the result of a map
114050 expansion, the terminal shall be alerted and the <ESC> character shall be discarded, but it shall
114051 not be an error.

114052 Otherwise, it shall be an error.

114053 *Current line*: Unchanged.

114054 *Current column*: Unchanged.

114055 **Search for tagstring**

114056 *Synopsis*: `<control>-]`

114057 If the current character is not a word or <blank>, it shall be an error.

114058 This command shall be equivalent to the *ex* **tag** command, with the argument to that command
114059 defined as follows.

114060 If the current character is a <blank>:

114061 1. Skip all <blank> characters after the cursor up to the end of the line.

114062 2. If the end of the line is reached, it shall be an error.

114063 Then, the argument to the *ex* **tag** command shall be the current character and all subsequent
114064 characters, up to the first non-word character or the end of the line.

114065 **Move Cursor Forward**

114066 *Synopsis*: **[***count***]** `<space>`
114067 **[***count***]** `l` (ell)

114068 If there are less than *count* non-<newline> characters after the cursor on the current line, *count*
114069 shall be adjusted to the number of non-<newline> characters after the cursor on the line.

114070 If used as a motion command:

114071 1. If the current or *count*th character after the cursor is the last non-<newline> in the line, the
114072 text region shall be comprised of the current character up to and including the last
114073 non-<newline> in the line. Otherwise, the text region shall be from the current character
114074 up to, but not including, the *count*th character after the cursor.

114075 2. Any text copied to a buffer shall be in character mode.

114076 If not used as a motion command:

114077 If there are no non-<newline> characters after the current character on the current line, it shall be
114078 an error.

114079 *Current line*: Unchanged.

114080 *Current column*: Set to the last column that displays any portion of the *count*th character after the
114081 current character.

Replace Text with Results from Shell Command

Synopsis: **[***count***]** **!** *motion shell-commands* <newline>

If the motion command is the **!** command repeated:

1. If the edit buffer is empty and no *count* was supplied, the command shall be the equivalent of the *ex* **:read !** command, with the text input, and no text shall be copied to any buffer.
2. Otherwise:
    a. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.
    b. The text region shall be from the current line up to and including the next *count* −1 lines.

Otherwise, the text region shall be the lines in which any character of the text region specified by the motion command appear.

Any text copied to a buffer shall be in line mode.

This command shall be equivalent to the *ex* **!** command for the specified lines.

Move Cursor to End-of-Line

Synopsis: **[***count***]** **$**

It shall be an error if there are less than (*count* −1) lines after the current line in the edit buffer.

If used as a motion command:

1. If *count* is 1:
    a. It shall be an error if the line is empty.
    b. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line, inclusive, and any text copied to a buffer shall be in character mode.
2. Otherwise, if the starting cursor position is at or before the first non-<blank> in the line, the text region shall consist of the current and the next *count* −1 lines, and any text saved to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line that is *count* −1 lines forward from the current line, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the *current line* + *count*−1.

Current column: The current column is set to the last display line column of the last non-<newline> in the line, or column position 1 if the line is empty.

The current column shall be adjusted to be on the last display line column of the last non-<newline> of the current line as subsequent commands change the current line, until a command changes the current column.

Move to Matching Character

Synopsis: %

If the character at the current position is not a parenthesis, bracket, or curly brace, search forward in the line to the first one of those characters. If no such character is found, it shall be an error.

The matching character shall be the parenthesis, bracket, or curly brace matching the parenthesis, bracket, or curly brace, respectively, that was at the current position or that was found on the current line.

Matching shall be determined as follows, for an open parenthesis:

1. Set a counter to 1.
2. Search forwards until a parenthesis is found or the end of the edit buffer is reached.
3. If the end of the edit buffer is reached, it shall be an error.
4. If an open parenthesis is found, increment the counter by 1.
5. If a close parenthesis is found, decrement the counter by 1.
6. If the counter is zero, the current character is the matching character.

Matching for a close parenthesis shall be equivalent, except that the search shall be backwards, from the starting character to the beginning of the buffer, a close parenthesis shall increment the counter by 1, and an open parenthesis shall decrement the counter by 1.

Matching for brackets and curly braces shall be equivalent, except that searching shall be done for open and close brackets or open and close curly braces. It is implementation-defined whether other characters are searched for and matched as well.

If used as a motion command:

1. If the matching cursor was after the starting cursor in the edit buffer, and the starting cursor position was at or before the first non-<blank> non-<newline> in the starting line, and the matching cursor position was at or after the last non-<blank> non-<newline> in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
2. If the matching cursor was before the starting cursor in the edit buffer, and the starting cursor position was at or after the last non-<blank> non-<newline> in the starting line, and the matching cursor position was at or before the first non-<blank> non-<newline> in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of the starting character to the matching character, inclusive, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the matching character is located.

Current column: Set to the last column where any portion of the matching character is displayed.

Repeat Substitution

Synopsis: `&`

Repeat the previous substitution command. This command shall be equivalent to the *ex* **&** command with the current line as its addresses, and without *options*, *count*, or *flags*.

Return to Previous Context at Beginning of Line

Synopsis: `' character`

It shall be an error if there is no line in the edit buffer marked by *character*.

If used as a motion command:

1. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
2. The text region shall consist of the starting line up to and including the marked line, and any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to the line referenced by the mark.

Current column: Set to non-<blank>.

Return to Previous Context

Synopsis: `` ` character ``

It shall be an error if the marked line is no longer in the edit buffer. If the marked line no longer contains a character in the saved numbered character position, it shall be as if the marked position is the first non-<blank>.

If used as a motion command:

1. It shall be an error if the marked cursor references the same character in the edit buffer as the starting cursor.
2. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
3. If the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the marked cursor line is empty or the marked cursor references the first character of the marked cursor line, the text region shall consist of all lines containing characters from the starting cursor to the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in line mode.
4. Otherwise, if the marked cursor line is empty or the marked cursor references a character at or before the first non-<blank> non-<newline> of the marked cursor line, the region of text shall be from the starting cursor to the last non-<newline> of the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in character mode.
5. Otherwise, the region of text shall be from the starting cursor (inclusive), to the marked cursor (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line referenced by the mark.

Current column: Set to the last column in which any portion of the character referenced by the

mark is displayed.

Return to Previous Section

Synopsis: **[***count***]** [[

Move the cursor backward through the edit buffer to the first character of the previous section boundary, *count* times.

If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the *count*th next boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the last line of the edit buffer or the last non-<newline> of the last line of the edit buffer, the text region shall consist of the last character in the edit buffer up to and including the starting character, and any text saved to a buffer shall be in character mode.
3. Otherwise, the text region shall consist of the starting character up to but not including the first character in the *count*th next boundary, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the *count*th next boundary in the edit buffer starts.

Current column: Set to the last column in which any portion of the first character of the *count*th next boundary is displayed, or column position 1 if the line is empty.

Move to Next Section

Synopsis: **[***count***]**]]

Move the cursor forward through the edit buffer to the first character of the next section boundary, *count* times.

If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the *count*th previous boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the first line of the edit buffer, the text region shall consist of the first character in the edit buffer up to but not including the starting character, and any text copied to a buffer shall be in character mode.
3. Otherwise, the text region shall consist of the first character in the *count*th previous section boundary up to but not including the starting character, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the *count*th previous boundary in the edit buffer starts.

Current column: Set to the last column in which any portion of the first character of the *count*th previous boundary is displayed, or column position 1 if the line is empty.

Move to First Non-<blank> Position on Current Line

Synopsis: ^

If used as a motion command:

1. If the line has no non-<blank> non-<newline> characters, or if the cursor is at the first non-<blank> non-<newline> of the line, it shall be an error.
2. If the cursor is before the first non-<blank> non-<newline> of the line, the text region shall be comprised of the current character, up to, but not including, the first non-<blank> non-<newline> of the line.
3. If the cursor is after the first non-<blank> non-<newline> of the line, the text region shall be from the character before the starting cursor up to and including the first non-<blank> non-<newline> of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to non-<blank>.

Current and Line Above

Synopsis: **[***count***]** _

If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. If *count* is less than 2, the text region shall be the current line.
2. Otherwise, the text region shall include the starting line and the next *count* −1 lines.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to current line + *count* −1.

Current column: Set to non-<blank>.

Move Back to Beginning of Sentence

Synopsis: **[***count***]** (

Move backward to the beginning of a sentence. This command shall be equivalent to the **[[** command, with the exception that sentence boundaries shall be used instead of section boundaries.

Move Forward to Beginning of Sentence

Synopsis: **[***count***]**)

Move forward to the beginning of a sentence. This command shall be equivalent to the **]]** command, with the exception that sentence boundaries shall be used instead of section boundaries.

Move Back to Preceding Paragraph

Synopsis: **[***count***]** {

Move back to the beginning of the preceding paragraph. This command shall be equivalent to the **[[** command, with the exception that paragraph boundaries shall be used instead of section boundaries.

Move Forward to Next Paragraph

Synopsis: **[***count***]** }

Move forward to the beginning of the next paragraph. This command shall be equivalent to the **]]** command, with the exception that paragraph boundaries shall be used instead of section boundaries.

Move to Specific Column Position

Synopsis: **[***count***]** |

For the purposes of this command, lines that are too long for the current display and that have been folded shall be treated as having a single, 1–based, number of columns.

If there are less than *count* columns in which characters from the current line are displayed on the screen, *count* shall be adjusted to be the last column in which any portion of the line is displayed on the screen.

If used as a motion command:

1. If the line is empty, or the cursor character is the same as the character on the *count*th column of the line, it shall be an error.
2. If the cursor is before the *count*th column of the line, the text region shall be comprised of the current character, up to but not including the character on the *count*th column of the line.
3. If the cursor is after the *count*th column of the line, the text region shall be from the character before the starting cursor up to and including the character on the *count*th column of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the character that is displayed in the *count* column of the line is displayed.

Reverse Find Character

Synopsis: **[***count***]** **,**

If the last **F**, **f**, **T**, or **t** command was **F**, **f**, **T**, or **t**, this command shall be equivalent to an **f**, **F**, **t**, or **T** command, respectively, with the specified *count* and the same search character.

If there was no previous **F**, **f**, **T**, or **t** command, it shall be an error.

Repeat

Synopsis: `[count] .`

Repeat the last **!**, **<**, **>**, **A**, **C**, **D**, **I**, **J**, **O**, **P**, **R**, **S**, **X**, **Y**, **a**, **c**, **d**, **i**, **o**, **p**, **r**, **s**, **x**, **y**, or ~ command. It shall be an error if none of these commands have been executed. Commands (other than commands that enter text input mode) executed as a result of map expansions, shall not change the value of the last repeatable command.

Repeated commands with associated motion commands shall repeat the motion command as well; however, any specified *count* shall replace the *count*(s) that were originally specified to the repeated command or its associated motion command.

If the motion component of the repeated command is **f**, **F**, **t**, or **T**, the repeated command shall not set the remembered search character for the **;** and **,** commands.

If the repeated command is **p** or **P**, and the buffer associated with that command was a numeric buffer named with a number less than 9, the buffer associated with the repeated command shall be set to be the buffer named by the name of the previous buffer logically incremented by 1.

If the repeated character is a text input command, the input text associated with that command is repeated literally:

> Input characters are neither macro or abbreviation-expanded.
>
> Input characters are not interpreted in any special way with the exception that <newline>, <carriage-return>, and <control>-T behave as described in Input Mode Commands in vi (on page 3410).

Current line: Set as described for the repeated command.

Current column: Set as described for the repeated command.

Find Regular Expression

Synopsis: /

If the input line contains no non-<newline> characters, it shall be equivalent to a line containing only the last regular expression encountered. The enhanced regular expressions supported by *vi* are described in Regular Expressions in ex (on page 2734).

Otherwise, the line shall be interpreted as one or more regular expressions, optionally followed by an address offset or a *vi* **z** command.

If the regular expression is not the last regular expression on the line, or if a line offset or **z** command is specified, the regular expression shall be terminated by an unescaped '/' character, which shall not be used as part of the regular expression. If the regular expression is not the first regular expression on the line, it shall be preceded by zero or more <blank> characters, a <semicolon>, zero or more <blank> characters, and a leading '/' character, which shall not be interpreted as part of the regular expression. It shall be an error to precede any regular expression with any characters other than these.

Each search shall begin from the character after the first character of the last match (or, if it is the first search, after the cursor). If the **wrapscan** edit option is set, the search shall continue to the character before the starting cursor character; otherwise, to the end of the edit buffer. It shall be an error if any search fails to find a match, and an informational message to this effect shall be displayed.

An optional address offset (see Addressing in ex, on page 2703) can be specified after the last regular expression by including a trailing '/' character after the regular expression and

specifying the address offset. This offset will be from the line containing the match for the last regular expression specified. It shall be an error if the line offset would indicate a line address less than 1 or greater than the last line in the edit buffer. An address offset of zero shall be supported. It shall be an error to follow the address offset with any other characters than <blank> characters.

If not used as a motion command, an optional **z** command (see Redraw Window, on page 3409) can be specified after the last regular expression by including a trailing `'/'` character after the regular expression, zero or more <blank> characters, a `'z'`, zero or more <blank> characters, an optional new **window** edit option value, zero or more <blank> characters, and a location character. The effect shall be as if the **z** command was executed after the **/** command. It shall be an error to follow the **z** command with any other characters than <blank> characters.

The remembered search direction shall be set to forward.

If used as a motion command:

1. It shall be an error if the last match references the same character in the edit buffer as the starting cursor.
2. If any address offset is specified, the last match shall be adjusted by the specified offset as described previously.
3. If the starting cursor is after the last match, then the locations of the starting cursor and the last match in the edit buffer shall be logically swapped.
4. If any address offset is specified, the text region shall consist of all lines containing characters from the starting cursor to the last match line, inclusive, and any text copied to a buffer shall be in line mode.
5. Otherwise, if the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the last match line is empty or the last match starts at the first character of the last match line, the text region shall consist of all lines containing characters from the starting cursor to the line before the last match line, inclusive, and any text copied to a buffer shall be in line mode.
6. Otherwise, if the last match line is empty or the last match begins at a character at or before the first non-<blank> non-<newline> of the last match line, the region of text shall be from the current cursor to the last non-<newline> of the line before the last match line, inclusive, and any text copied to a buffer shall be in character mode.
7. Otherwise, the region of text shall be from the current cursor (inclusive), to the first character of the last match (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: If a match is found, set to the last matched line plus the address offset, if any; otherwise, unchanged.

Current column: Set to the last column on which any portion of the first character in the last matched string is displayed, if a match is found; otherwise, unchanged.

114388 **Move to First Character in Line**

114389 *Synopsis*: `0` (zero)

114390 Move to the first character on the current line. The character `'0'` shall not be interpreted as a
114391 command if it is immediately preceded by a digit.

114392 If used as a motion command:

114393 1. If the cursor character is the first character in the line, it shall be an error.

114394 2. The text region shall be from the character before the cursor character up to and including
114395 the first character in the line.

114396 3. Any text copied to a buffer shall be in character mode.

114397 If not used as a motion command:

114398 *Current line*: Unchanged.

114399 *Current column*: The last column in which any portion of the first character in the line is
114400 displayed, or if the line is empty, unchanged.

114401 **Execute an ex Command**

114402 *Synopsis*: **:**

114403 Execute one or more *ex* commands.

114404 If any portion of the screen other than the last line of the screen was overwritten by any *ex*
114405 command (except **shell**), *vi* shall display a message indicating that it is waiting for an input from
114406 the user, and shall then read a character. This action may also be taken for other, unspecified
114407 reasons.

114408 If the next character entered is a `':'`, another *ex* command shall be accepted and executed. Any
114409 other character shall cause the screen to be refreshed and *vi* shall return to command mode.

114410 *Current line*: As specified for the *ex* command.

114411 *Current column*: As specified for the *ex* command.

114412 **Repeat Find**

114413 *Synopsis*: **[***count***]** **;**

114414 This command shall be equivalent to the last **F**, **f**, **T**, or **t** command, with the specified *count*, and
114415 with the same search character used for the last **F**, **f**, **T**, or **t** command. If there was no previous **F**,
114416 **f**, **T**, or **t** command, it shall be an error.

114417 **Shift Left**

114418 *Synopsis*: **[***count***]** *< motion*

114419 If the motion command is the **<** command repeated:

114420 1. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an
114421 error.

114422 2. The text region shall be from the current line, up to and including the next *count* −1 lines.

114423 Shift any line in the text region specified by the *count* and motion command one shiftwidth (see
114424 the *ex* **shiftwidth** option) toward the start of the line, as described by the *ex* **<** command. The
114425 unshifted lines shall be copied to the unnamed buffer in line mode.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column: Set to non-<blank>.

Shift Right

Synopsis: `[`*`count`*`] > `*`motion`*

If the motion command is the **>** command repeated:

1. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.
2. The text region shall be from the current line, up to and including the next *count* −1 lines.

Shift any line with characters in the text region specified by the *count* and motion command one shiftwidth (see the *ex* **shiftwidth** option) away from the start of the line, as described by the *ex* **>** command. The unshifted lines shall be copied into the unnamed buffer in line mode.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column: Set to non-<blank>.

Scan Backwards for Regular Expression

Synopsis: `?`

Scan backwards; the **?** command shall be equivalent to the **/** command (see Find Regular Expression, on page 3392) with the following exceptions:

1. The input prompt shall be a `'?'`.
2. Each search shall begin from the character before the first character of the last match (or, if it is the first search, the character before the cursor character).
3. The search direction shall be from the cursor toward the beginning of the edit buffer, and the **wrapscan** edit option shall affect whether the search wraps to the end of the edit buffer and continues.
4. The remembered search direction shall be set to backward.

Execute

Synopsis: `@`*`buffer`*

If the *buffer* is specified as **@**, the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

Behave as if the contents of the named buffer were entered as standard input. After each line of a line-mode buffer, and all but the last line of a character mode buffer, behave as if a <newline> were entered as standard input.

If an error occurs during this process, an error message shall be written, and no more characters resulting from the execution of this command shall be processed.

If a *count* is specified, behave as if that count were entered as user input before the characters from the **@** buffer were entered.

Current line: As specified for the individual commands.

Current column: As specified for the individual commands.

Reverse Case

Synopsis: **[***count***]** ~

Reverse the case of the current character and the next *count* −1 characters, such that lowercase characters that have uppercase counterparts shall be changed to uppercase characters, and uppercase characters that have lowercase counterparts shall be changed to lowercase characters, as prescribed by the current locale. No other characters shall be affected by this command.

If there are less than *count* −1 characters after the cursor in the edit buffer, *count* shall be adjusted to the number of characters after the cursor in the edit buffer minus 1.

For the purposes of this command, the next character after the last non-<newline> on the line shall be the next character in the edit buffer.

Current line: Set to the line including the (*count*−1)th character after the cursor.

Current column: Set to the last column in which any portion of the (*count*−1)th character after the cursor is displayed.

Append

Synopsis: **[***count***]** a

Enter text input mode after the current cursor position. No characters already in the edit buffer shall be affected by this command. A *count* shall cause the input text to be appended *count* −1 more times to the end of the input.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi, on page 3410).

Append at End-of-Line

Synopsis: **[***count***]** A

This command shall be equivalent to the *vi* command:

```
$ [ count ] a
```

(see Append).

Move Backward to Preceding Word

Synopsis: **[***count***]** b

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the **B** command.

114496 **Move Backward to Preceding Bigword**

114497 *Synopsis*: **[***count***]** B

114498 If the edit buffer is empty or the cursor is on the first character of the edit buffer, it shall be an
114499 error. If less than *count* bigwords begin between the cursor and the start of the edit buffer, *count*
114500 shall be adjusted to the number of bigword beginnings between the cursor and the start of the
114501 edit buffer.

114502 If used as a motion command:

114503 1. The text region shall be from the first character of the *count*th previous bigword beginning
114504 up to but not including the cursor character.

114505 2. Any text copied to a buffer shall be in character mode.

114506 If not used as a motion command:

114507 *Current line*: Set to the line containing the *current column*.

114508 *Current column*: Set to the last column upon which any part of the first character of the *count*th
114509 previous bigword is displayed.

114510 **Change**

114511 *Synopsis*: **[***buffer***][***count***]** c *motion*

114512 If the motion command is the **c** command repeated:

114513 1. The buffer text shall be in line mode.

114514 2. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an
114515 error.

114516 3. The text region shall be from the current line up to and including the next *count* −1 lines.

114517 Otherwise, the buffer text mode and text region shall be as specified by the motion command.

114518 The replaced text shall be copied into *buffer*, if specified, and into the unnamed buffer. If the text
114519 to be replaced contains characters from more than a single line, or the buffer text is in line mode,
114520 the replaced text shall be copied into the numeric buffers as well.

114521 If the buffer text is in line mode:

114522 1. Any lines that contain characters in the region shall be deleted, and the editor shall enter
114523 text input mode at the beginning of a new line which shall replace the first line deleted.

114524 2. If the **autoindent** edit option is set, **autoindent** characters equal to the **autoindent**
114525 characters on the first line deleted shall be inserted as if entered by the user.

114526 Otherwise, if characters from more than one line are in the region of text:

114527 1. The text shall be deleted.

114528 2. Any text remaining in the last line in the text region shall be appended to the first line in
114529 the region, and the last line in the region shall be deleted.

114530 3. The editor shall enter text input mode after the last character not deleted from the first
114531 line in the text region, if any; otherwise, on the first column of the first line in the region.

Otherwise:

1. If the glyph for '$' is smaller than the region, the end of the region shall be marked with a '$'.
2. The editor shall enter text input mode, overwriting the region of text.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi, on page 3410).

Change to End-of-Line

Synopsis: **[***buffer***][***count***]** C

This command shall be equivalent to the *vi* command:

[*buffer***][***count***]** c$

See the **c** command.

Delete

Synopsis: **[***buffer***][***count***]** d *motion*

If the motion command is the **d** command repeated:

1. The buffer text shall be in line mode.
2. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* −1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

If in open mode, and the current line is deleted, and the line remains on the display, an '@' character shall be displayed as the first glyph of that line.

Delete the region of text into *buffer*, if specified, and into the unnamed buffer. If the text to be deleted contains characters from more than a single line, or the buffer text is in line mode, the deleted text shall be copied into the numeric buffers, as well.

Current line: Set to the first text region line that appears in the edit buffer, unless that line has been deleted, in which case it shall be set to the last line in the edit buffer, or line 1 if the edit buffer is empty.

Current column:

1. If the line is empty, set to column position 1.
2. Otherwise, if the buffer text is in line mode or the motion was from the cursor toward the end of the edit buffer:
   a. If a character from the current line is displayed in the current column, set to the last column that displays any portion of that character.
   b. Otherwise, set to the last column in which any portion of any character in the line is displayed.
3. Otherwise, if a character is displayed in the column that began the text region, set to the last column that displays any portion of that character.

4. Otherwise, set to the last column in which any portion of any character in the line is displayed.

Delete to End-of-Line

Synopsis: **[***buffer***]** D

Delete the text from the current position to the end of the current line; equivalent to the *vi* command:

[*buffer***]** d$

Move to End-of-Word

Synopsis: **[***count***]** e

With the exception that words are used instead of bigwords as the delimiter, this command shall be equivalent to the **E** command.

Move to End-of-Bigword

Synopsis: **[***count***]** E

If the edit buffer is empty it shall be an error. If less than *count* bigwords end between the cursor and the end of the edit buffer, *count* shall be adjusted to the number of bigword endings between the cursor and the end of the edit buffer.

If used as a motion command:

1. The text region shall be from the last character of the *count*th next bigword up to and including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line containing the current column.

Current column: Set to the last column upon which any part of the last character of the *count*th next bigword is displayed.

Find Character in Current Line (Forward)

Synopsis: **[***count***]** f *character*

It shall be an error if *count* occurrences of the character do not occur after the cursor in the line.

If used as a motion command:

1. The text range shall be from the cursor character up to and including the *count*th occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the *count*th occurrence of the specified character after the cursor appears in the line.

114604 **Find Character in Current Line (Reverse)**

114605 *Synopsis*: **[***count***]** F *character*

114606 It shall be an error if *count* occurrences of the character do not occur before the cursor in the line.

114607 If used as a motion command:

114608 1. The text region shall be from the *count*th occurrence of the specified character before the
114609 cursor, up to, but not including the cursor character.

114610 2. Any text copied to a buffer shall be in character mode.

114611 If not used as a motion command:

114612 *Current line*: Unchanged.

114613 *Current column*: Set to the last column in which any portion of the *count*th occurrence of the
114614 specified character before the cursor appears in the line.

114615 **Move to Line**

114616 *Synopsis*: **[***count***]** G

114617 If *count* is not specified, it shall default to the last line of the edit buffer. If *count* is greater than
114618 the last line of the edit buffer, it shall be an error.

114619 If used as a motion command:

114620 1. The text region shall be from the cursor line up to and including the specified line.

114621 2. Any text copied to a buffer shall be in line mode.

114622 If not used as a motion command:

114623 *Current line*: Set to *count* if *count* is specified; otherwise, the last line.

114624 *Current column*: Set to non-<blank>.

114625 **Move to Top of Screen**

114626 *Synopsis*: **[***count***]** H

114627 If the beginning of the line *count* greater than the first line of which any portion appears on the
114628 display does not exist, it shall be an error.

114629 If used as a motion command:

114630 1. If in open mode, the text region shall be the current line.

114631 2. Otherwise, the text region shall be from the starting line up to and including (the first line
114632 of the display + *count* –1).

114633 3. Any text copied to a buffer shall be in line mode.

114634 If not used as a motion command:

114635 If in open mode, this command shall set the current column to non-<blank> and do nothing else.

114636 Otherwise, it shall set the current line and current column as follows.

114637 *Current line*: Set to (the first line of the display + *count* –1).

114638 *Current column*: Set to non-<blank>.

114639 **Insert Before Cursor**

114640 *Synopsis*: **[***count***]** i

114641 Enter text input mode before the current cursor position. No characters already in the edit buffer
114642 shall be affected by this command. A *count* shall cause the input text to be appended *count* –1
114643 more times to the end of the input.

114644 *Current line/column*: As specified for the text input commands (see Input Mode Commands in vi, on page 3410).

114646 **Insert at Beginning of Line**

114647 *Synopsis*: **[***count***]** I

114648 This command shall be equivalent to the *vi* command ^[*count*]**i**.

114649 **Join**

114650 *Synopsis*: **[***count***]** J

114651 If the current line is the last line in the edit buffer, it shall be an error.

114652 This command shall be equivalent to the *ex* **join** command with no addresses, and an *ex*
114653 command *count* value of 1 if *count* was not specified or if a *count* of 1 was specified, and an *ex*
114654 command *count* value of *count* –1 for any other value of *count*, except that the current line and
114655 column shall be set as follows.

114656 *Current line*: Unchanged.

114657 *Current column*: The last column in which any portion of the character following the last
114658 character in the initial line is displayed, or the last non-<newline> in the line if no characters
114659 were appended.

114660 **Move to Bottom of Screen**

114661 *Synopsis*: **[***count***]** L

114662 If the beginning of the line *count* less than the last line of which any portion appears on the
114663 display does not exist, it shall be an error.

114664 If used as a motion command:

114665 1. If in open mode, the text region shall be the current line.

114666 2. Otherwise, the text region shall include all lines from the starting cursor line to (the last
114667 line of the display –(*count* –1)).

114668 3. Any text copied to a buffer shall be in line mode.

114669 If not used as a motion command:

114670 1. If in open mode, this command shall set the current column to non-<blank> and do
114671 nothing else.

114672 2. Otherwise, it shall set the current line and current column as follows.

114673 *Current line*: Set to (the last line of the display –(*count* –1)).

114674 *Current column*: Set to non-<blank>.

114675 **Mark Position**

114676 *Synopsis*: `m letter`

114677 This command shall be equivalent to the *ex* **mark** command with the specified character as an
114678 argument.

114679 **Move to Middle of Screen**

114680 *Synopsis*: `M`

114681 The middle line of the display shall be calculated as follows:

114682 `(the top line of the display) + (((number of lines displayed) +1) /2) −1`

114683 If used as a motion command:

114684 1. If in open mode, the text region shall be the current line.

114685 2. Otherwise, the text region shall include all lines from the starting cursor line up to and
114686 including the middle line of the display.

114687 3. Any text copied to a buffer shall be in line mode.

114688 If not used as a motion command:

114689 If in open mode, this command shall set the current column to non-<blank> and do nothing else.

114690 Otherwise, it shall set the current line and current column as follows.

114691 *Current line*: Set to the middle line of the display.

114692 *Current column*: Set to non-<blank>.

114693 **Repeat Regular Expression Find (Forward)**

114694 *Synopsis*: `n`

114695 If the remembered search direction was forward, the **n** command shall be equivalent to the *vi* **/**
114696 command with no characters entered by the user. Otherwise, it shall be equivalent to the *vi* **?**
114697 command with no characters entered by the user.

114698 If the **n** command is used as a motion command for the **!** command, the editor shall not enter
114699 text input mode on the last line on the screen, and shall behave as if the user entered a single
114700 `'!'` character as the text input.

114701 **Repeat Regular Expression Find (Reverse)**

114702 *Synopsis*: `N`

114703 Scan for the next match of the last pattern given to **/** or **?**, but in the reverse direction; this is the
114704 reverse of **n**.

114705 If the remembered search direction was forward, the **N** command shall be equivalent to the *vi* **?**
114706 command with no characters entered by the user. Otherwise, it shall be equivalent to the *vi* **/**
114707 command with no characters entered by the user. If the **N** command is used as a motion
114708 command for the **!** command, the editor shall not enter text input mode on the last line on the
114709 screen, and shall behave as if the user entered a single **!** character as the text input.

114710 **Insert Empty Line Below**

114711 *Synopsis*: `o`

114712 Enter text input mode in a new line appended after the current line. A *count* shall cause the input
114713 text to be appended *count* −1 more times to the end of the already added text, each time starting
114714 on a new, appended line.

114715 *Current line/column*: As specified for the text input commands (see Input Mode Commands in vi,
114716 on page 3410).

114717 **Insert Empty Line Above**

114718 *Synopsis*: `O`

114719 Enter text input mode in a new line inserted before the current line. A *count* shall cause the input
114720 text to be appended *count* −1 more times to the end of the already added text, each time starting
114721 on a new, appended line.

114722 *Current line/column*: As specified for the text input commands (see Input Mode Commands in vi,
114723 on page 3410).

114724 **Put from Buffer Following**

114725 *Synopsis*: **[***buffer***]** `p`

114726 If no *buffer* is specified, the unnamed buffer shall be used.

114727 If the buffer text is in line mode, the text shall be appended below the current line, and each line
114728 of the buffer shall become a new line in the edit buffer. A *count* shall cause the buffer text to be
114729 appended *count* −1 more times to the end of the already added text, each time starting on a new,
114730 appended line.

114731 If the buffer text is in character mode, the text shall be appended into the current line after the
114732 cursor, and each line of the buffer other than the first and last shall become a new line in the edit
114733 buffer. A *count* shall cause the buffer text to be appended *count* −1 more times to the end of the
114734 already added text, each time starting after the last added character.

114735 *Current line*: If the buffer text is in line mode, set the line to line +1; otherwise, unchanged.

114736 *Current column*: If the buffer text is in line mode:

114737 1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any
114738 portion of the first non-<blank> in the line is displayed.

114739 2. If there is no non-<blank> in the first line of the buffer, set to the last column on which
114740 any portion of the last non-<newline> in the first line of the buffer is displayed.

114741 If the buffer text is in character mode:

114742 1. If the text in the buffer is from more than a single line, then set to the last column on
114743 which any portion of the first character from the buffer is displayed.

114744 2. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any
114745 portion of the last character from the buffer is displayed.

114746 3. Otherwise, set to the first column on which any portion of the first character from the
114747 buffer is displayed.

Put from Buffer Before

Synopsis: **[***buffer***]** P

If no *buffer* is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be inserted above the current line, and each line of the buffer shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* –1 more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be inserted into the current line before the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* –1 more times to the end of the already added text, each time starting after the last added character.

Current line: Unchanged.

Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of that character is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
2. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
3. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

Enter ex Mode

Synopsis: Q

Leave visual or open mode and enter *ex* command mode.

Current line: Unchanged.

Current column: Unchanged.

Replace Character

Synopsis: **[***count***]** r *character*

Replace the *count* characters at and after the cursor with the specified character. If there are less than *count* non-<newline> characters at and after the cursor on the line, it shall be an error.

If character is <control>-V, any next character other than the <newline> shall be stripped of any special meaning and used as a literal character.

If character is <ESC>, no replacement shall be made and the current line and current column shall be unchanged.

If character is <carriage-return> or <newline>, *count* new lines shall be appended to the current line. All but the last of these lines shall be empty. *count* characters at and after the cursor shall be

114787 discarded, and any remaining characters after the cursor in the current line shall be moved to the
114788 last of the new lines. If the **autoindent** edit option is set, they shall be preceded by the same
114789 number of **autoindent** characters found on the line from which the command was executed.

114790 *Current line*: Unchanged unless the replacement character is a <carriage-return> or <newline>, in
114791 which case it shall be set to line + *count*.

114792 *Current column*: Set to the last column position on which a portion of the last replaced character
114793 is displayed, or if the replacement character caused new lines to be created, set to non-<blank>.

114794 **Replace Characters**

114795 *Synopsis*: `R`

114796 Enter text input mode at the current cursor position possibly replacing text on the current line. A
114797 *count* shall cause the input text to be appended *count* −1 more times to the end of the input.

114798 *Current line/column*: As specified for the text input commands (see Input Mode Commands in vi,
114799 on page 3410).

114800 **Substitute Character**

114801 *Synopsis*: **[***buffer***][***count***]** `s`

114802 This command shall be equivalent to the *vi* command:

114803 **[***buffer***][***count***]** `c<space>`

114804 **Substitute Lines**

114805 *Synopsis*: **[***buffer***][***count***]** `S`

114806 This command shall be equivalent to the *vi* command:

114807 **[***buffer***][***count***]** `c_`

114808 **Move Cursor to Before Character (Forward)**

114809 *Synopsis*: **[***count***]** `t` *character*

114810 It shall be an error if *count* occurrences of the character do not occur after the cursor in the line.

114811 If used as a motion command:

114812 1. The text region shall be from the cursor up to but not including the *count*th occurrence of
114813 the specified character after the cursor.

114814 2. Any text copied to a buffer shall be in character mode.

114815 If not used as a motion command:

114816 *Current line*: Unchanged.

114817 *Current column*: Set to the last column in which any portion of the character before the *count*th
114818 occurrence of the specified character after the cursor appears in the line.

114819 **Move Cursor to After Character (Reverse)**

114820 *Synopsis*: `[`*count*`] T` *character*

114821 It shall be an error if *count* occurrences of the character do not occur before the cursor in the line.

114822 If used as a motion command:

114823 1. If the character before the cursor is the specified character, it shall be an error.

114824 2. The text region shall be from the character before the cursor up to but not including the
114825 *count*th occurrence of the specified character before the cursor.

114826 3. Any text copied to a buffer shall be in character mode.

114827 If not used as a motion command:

114828 *Current line*: Unchanged.

114829 *Current column*: Set to the last column in which any portion of the character after the *count*th
114830 occurrence of the specified character before the cursor appears in the line.

114831 **Undo**

114832 *Synopsis*: `u`

114833 This command shall be equivalent to the *ex* **undo** command except that the current line and
114834 current column shall be set as follows:

114835 *Current line*: Set to the first line added or changed if any; otherwise, move to the line preceding
114836 any deleted text if one exists; otherwise, move to line 1.

114837 *Current column*: If undoing an *ex* command, set to the first non-<blank>.

114838 Otherwise, if undoing a text input command:

114839 1. If the command was a **C**, **c**, **O**, **o**, **R**, **S**, or **s** command, the current column shall be set to
114840 the value it held when the text input command was entered.

114841 2. Otherwise, set to the last column in which any portion of the first character after the
114842 deleted text is displayed, or, if no non-<newline> characters follow the text deleted from
114843 this line, set to the last column in which any portion of the last non-<newline> in the line
114844 is displayed, or 1 if the line is empty.

114845 Otherwise, if a single line was modified (that is, not added or deleted) by the **u** command:

114846 1. If text was added or changed, set to the last column in which any portion of the first
114847 character added or changed is displayed.

114848 2. If text was deleted, set to the last column in which any portion of the first character after
114849 the deleted text is displayed, or, if no non-<newline> characters follow the deleted text,
114850 set to the last column in which any portion of the last non-<newline> in the line is
114851 displayed, or 1 if the line is empty.

114852 Otherwise, set to non-<blank>.

114853 **Undo Current Line**

114854 *Synopsis*: `U`

114855 Restore the current line to its state immediately before the most recent time that it became the
114856 current line.

114857 *Current line*: Unchanged.

114858 *Current column*: Set to the first column in the line in which any portion of the first character in
114859 the line is displayed.

114860 **Move to Beginning of Word**

114861 *Synopsis*: **[***count***]** `w`

114862 With the exception that words are used as the delimiter instead of bigwords, this command shall
114863 be equivalent to the **W** command.

114864 **Move to Beginning of Bigword**

114865 *Synopsis*: **[***count***]** `W`

114866 If the edit buffer is empty, it shall be an error. If there are less than *count* bigwords between the
114867 cursor and the end of the edit buffer, *count* shall be adjusted to move the cursor to the last
114868 bigword in the edit buffer.

114869 If used as a motion command:

114870 1. If the associated command is **c**, *count* is 1, and the cursor is on a <blank>, the region of
114871 text shall be the current character and no further action shall be taken.

114872 2. If there are less than *count* bigwords between the cursor and the end of the edit buffer,
114873 then the command shall succeed, and the region of text shall include the last character of
114874 the edit buffer.

114875 3. If there are <blank> characters or an end-of-line that precede the *count*th bigword, and the
114876 associated command is **c**, the region of text shall be up to and including the last character
114877 before the preceding <blank> characters or end-of-line.

114878 4. If there are <blank> characters or an end-of-line that precede the bigword, and the
114879 associated command is **d** or **y**, the region of text shall be up to and including the last
114880 <blank> before the start of the bigword or end-of-line.

114881 5. Any text copied to a buffer shall be in character mode.

114882 If not used as a motion command:

114883 1. If the cursor is on the last character of the edit buffer, it shall be an error.

114884 *Current line*: Set to the line containing the current column.

114885 *Current column*: Set to the last column in which any part of the first character of the *count*th next
114886 bigword is displayed.

Delete Character at Cursor

Synopsis: **[***buffer***][***count***]** x

Delete the *count* characters at and after the current character into *buffer*, if specified, and into the unnamed buffer.

If the line is empty, it shall be an error. If there are less than *count* non-<newline> characters at and after the cursor on the current line, *count* shall be adjusted to the number of non-<newline> characters at and after the cursor.

Current line: Unchanged.

Current column: If the line is empty, set to column position 1. Otherwise, if there were *count* or less non-<newline> characters at and after the cursor on the current line, set to the last column that displays any part of the last non-<newline> of the line. Otherwise, unchanged.

Delete Character Before Cursor

Synopsis: **[***buffer***][***count***]** X

Delete the *count* characters before the current character into *buffer*, if specified, and into the unnamed buffer.

If there are no characters before the current character on the current line, it shall be an error. If there are less than *count* previous characters on the current line, *count* shall be adjusted to the number of previous characters on the line.

Current line: Unchanged.

Current column: Set to (current column – the width of the deleted characters).

Yank

Synopsis: **[***buffer***][***count***]** y *motion*

Copy (yank) the region of text into *buffer*, if specified, and into the unnamed buffer.

If the motion command is the **y** command repeated:

1. The buffer shall be in line mode.
2. If there are less than *count* –1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* –1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column:

1. If the motion was from the current cursor position toward the end of the edit buffer, unchanged.
2. Otherwise, if the current line is empty, set to column position 1.
3. Otherwise, set to the last column that displays any part of the first character in the file that is part of the text region specified by the motion command.

114925 **Yank Current Line**

114926 *Synopsis*: **[***buffer***][***count***]** Y

114927 This command shall be equivalent to the *vi* command:

114928 **[***buffer***][***count***]** y_

114929 **Redraw Window**

114930 If in open mode, the **z** command shall have the Synopsis:

114931 *Synopsis*: **[***count***]** z

114932 If *count* is not specified, it shall default to the **window** edit option –1. The **z** command shall be
114933 equivalent to the *ex* **z** command, with a type character of **=** and a *count* of *count* –2, except that
114934 the current line and current column shall be set as follows, and the **window** edit option shall not
114935 be affected. If the calculation for the *count* argument would result in a negative number, the
114936 *count* argument to the *ex* **z** command shall be zero. A blank line shall be written after the last line
114937 is written.

114938 *Current line*: Unchanged.

114939 *Current column*: Unchanged.

114940 If not in open mode, the **z** command shall have the following Synopsis:

114941 *Synopsis*: **[***line***]** z **[***count***]** *character*

114942 If *line* is not specified, it shall default to the current line. If *line* is specified, but is greater than the
114943 number of lines in the edit buffer, it shall default to the number of lines in the edit buffer.

114944 If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in the
114945 *ex* **window** command), and the screen shall be redrawn.

114946 *line* shall be placed as specified by the following characters:

114947 <newline>, <carriage-return>
114948 Place the beginning of the line on the first line of the display.

114949 **.** Place the beginning of the line in the center of the display. The middle line of the display
114950 shall be calculated as described for the **M** command.

114951 – Place an unspecified portion of the line on the last line of the display.

114952 + If *line* was specified, equivalent to the <newline> case. If *line* was not specified, display a
114953 screen where the first line of the display shall be (current last line) +1. If there are no lines
114954 after the last line in the display, it shall be an error.

114955 ^ If *line* was specified, display a screen where the last line of the display shall contain an
114956 unspecified portion of the first line of a display that had an unspecified portion of the
114957 specified line on the last line of the display. If this calculation results in a line before the
114958 beginning of the edit buffer, display the first screen of the edit buffer.

114959 Otherwise, display a screen where the last line of the display shall contain an unspecified
114960 portion of (current first line –1). If this calculation results in a line before the beginning of
114961 the edit buffer, it shall be an error.

Current line: If *line* and the `'^'` character were specified:

1. If the first screen was displayed as a result of the command attempting to display lines before the beginning of the edit buffer: if the first screen was already displayed, unchanged; otherwise, set to (current first line –1).
2. Otherwise, set to the last line of the display.

If *line* and the `'+'` character were specified, set to the first line of the display.

Otherwise, if *line* was specified, set to *line*.

Otherwise, unchanged.

Current column: Set to non-<blank>.

Exit

Synopsis: `ZZ`

This command shall be equivalent to the *ex* **xit** command with no addresses, trailing **!**, or filename (see the *ex* **xit** command).

Input Mode Commands in vi

In text input mode, the current line shall consist of zero or more of the following categories, plus the terminating <newline>:

1. Characters preceding the text input entry point

   Characters in this category shall not be modified during text input mode.

2. **autoindent** characters

   autoindent characters shall be automatically inserted into each line that is created in text input mode, either as a result of entering a <newline> or <carriage-return> while in text input mode, or as an effect of the command itself; for example, **O** or **o** (see the *ex* **autoindent** command), as if entered by the user.

   It shall be possible to erase **autoindent** characters with the <control>-D command; it is unspecified whether they can be erased by <control>-H, <control>-U, and <control>-W characters. Erasing any **autoindent** character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

3. Text input characters

   Text input characters are the characters entered by the user. Erasing any text input character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

   Each text input character entered by the user (that does not have a special meaning) shall be treated as follows:

   a. The text input character shall be appended to the last character in the edit buffer from the first, second, or third categories.

   b. If there are no erase-columns on the screen, the text input command was the **R** command, and characters in the fifth category from the original line follow the cursor, the next such character shall be deleted from the edit buffer. If the **slowopen** edit option is not set, the corresponding glyph on the screen shall

become erase-columns.

c. If there are erase-columns on the screen, as many columns as they occupy, or as are necessary, shall be overwritten to display the text input character. (If only part of a multi-column glyph is overwritten, the remainder shall be left on the screen, and continue to be treated as erase-columns; it is unspecified whether the remainder of the glyph is modified in any way.)

d. If additional display line columns are needed to display the text input character:

   i. If the **slowopen** edit option is set, the text input characters shall be displayed on subsequent display line columns, overwriting any characters displayed in those columns.

   ii. Otherwise, any characters currently displayed on or after the column on the display line where the text input character is to be displayed shall be pushed ahead the number of display line columns necessary to display the rest of the text input character.

4. Erase-columns

   Erase-columns are not logically part of the edit buffer, appearing only on the screen, and may be overwritten on the screen by subsequent text input characters. When text input mode ends, all erase-columns shall no longer appear on the screen.

   Erase-columns are initially the region of text specified by the **c** command (see Change, on page 3397); however, erasing **autoindent** or text input characters causes the glyphs of the erased characters to be treated as erase-columns.

5. Characters following the text region for the **c** command, or the text input entry point for all other commands

   Characters in this category shall not be modified during text input mode, except as specified in category 3.b. for the **R** text input command, or as <blank> characters deleted when a <newline> or <carriage-return> is entered.

It is unspecified whether it is an error to attempt to erase past the beginning of a line that was created by the entry of a <newline> or <carriage-return> during text input mode. If it is not an error, the editor shall behave as if the erasing character was entered immediately after the last text input character entered on the previous line, and all of the non-<newline> characters on the current line shall be treated as erase-columns.

When text input mode is entered, or after a text input mode character is entered (except as specified for the special characters below), the cursor shall be positioned as follows:

1. On the first column that displays any part of the first erase-column, if one exists
2. Otherwise, if the **slowopen** edit option is set, on the first display line column after the last character in the first, second, or third categories, if one exists
3. Otherwise, the first column that displays any part of the first character in the fifth category, if one exists
4. Otherwise, the display line column after the last character in the first, second, or third categories, if one exists
5. Otherwise, on column position 1

The characters that are updated on the screen during text input mode are unspecified, other than that the last text input character shall always be updated, and, if the **slowopen** edit option is not

set, the current cursor character shall always be updated.

The following specifications are for command characters entered during text input mode.

NUL

Synopsis: `NUL`

If the first character of the text input is a NUL, the most recently input text shall be input as if entered by the user, and then text input mode shall be exited. The text shall be input literally; that is, characters are neither macro or abbreviation expanded, nor are any characters interpreted in any special manner. It is unspecified whether implementations shall support more than 256 bytes of remembered input text.

<control>-D

Synopsis: `<control>-D`

The <control>-D character shall have no special meaning when in text input mode for a line-oriented command (see Command Descriptions in vi, on page 3376).

This command need not be supported on block-mode terminals.

If the cursor does not follow an **autoindent** character, or an **autoindent** character and a `'0'` or `'^'` character:

1. If the cursor is in column position 1, the <control>-D character shall be discarded and no further action taken.
2. Otherwise, the <control>-D character shall have no special meaning.

If the last input character was a `'0'`, the cursor shall be moved to column position 1.

Otherwise, if the last input character was a `'^'`, the cursor shall be moved to column position 1. In addition, the **autoindent** level for the next input line shall be derived from the same line from which the **autoindent** level for the current input line was derived.

Otherwise, the cursor shall be moved back to the column after the previous shiftwidth (see the *ex* **shiftwidth** command) boundary.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 3410).

Current line: Unchanged.

Current column: Set to 1 if the <control>-D was preceded by a `'^'` or `'0'`; otherwise, set to (column –1) –((column –2) % **shiftwidth**).

<control>-H

Synopsis: `<control>-H`

If in text input mode for a line-oriented command, and there are no characters to erase, text input mode shall be terminated, no further action shall be done for this command, and the current line and column shall be unchanged.

If there are characters other than **autoindent** characters that have been input on the current line before the cursor, the cursor shall move back one character.

Otherwise, if there are **autoindent** characters on the current line before the cursor, it is

115084 implementation-defined whether the <control>-H command is an error or if the cursor moves
115085 back one **autoindent** character.

115086 Otherwise, if the cursor is in column position 1 and there are previous lines that have been
115087 input, it is implementation-defined whether the <control>-H command is an error or if it is
115088 equivalent to entering <control>-H after the last input character on the previous input line.

115089 Otherwise, it shall be an error.

115090 All of the glyphs on columns between the starting cursor position and (inclusively) the ending
115091 cursor position shall become erase-columns as described in Input Mode Commands in vi (on
115092 page 3410).

115093 The current erase character (see *stty*) shall cause an equivalent action to the <control>-H
115094 command, unless the previously inserted character was a <backslash>, in which case it shall be
115095 as if the literal current erase character had been inserted instead of the <backslash>.

115096 *Current line*: Unchanged, unless previously input lines are erased, in which case it shall be set to
115097 line –1.

115098 *Current column*: Set to the first column that displays any portion of the character backed up over.

115099 **<newline>**

115100 *Synopsis*: `<newline>`
115101 `<carriage-return>`
115102 `<control>-J`
115103 `<control>-M`

115104 If input was part of a line-oriented command, text input mode shall be terminated and the
115105 command shall continue execution with the input provided.

115106 Otherwise, terminate the current line. If there are no characters other than **autoindent** characters
115107 on the line, all characters on the line shall be discarded. Otherwise, it is unspecified whether the
115108 **autoindent** characters in the line are modified by entering these characters.

115109 Continue text input mode on a new line appended after the current line. If the **slowopen** edit
115110 option is set, the lines on the screen below the current line shall not be pushed down, but the
115111 first of them shall be cleared and shall appear to be overwritten. Otherwise, the lines of the
115112 screen below the current line shall be pushed down.

115113 If the **autoindent** edit option is set, an appropriate number of **autoindent** characters shall be
115114 added as a prefix to the line as described by the *ex* **autoindent** edit option.

115115 All columns after the cursor that are erase-columns (as described in Input Mode Commands in
115116 vi, on page 3410) shall be discarded.

115117 If the **autoindent** edit option is set, all <blank> characters immediately following the cursor shall
115118 be discarded.

115119 All remaining characters after the cursor shall be transferred to the new line, positioned after
115120 any **autoindent** characters.

115121 *Current line*: Set to current line +1.

115122 *Current column*: Set to the first column that displays any portion of the first character after the
115123 **autoindent** characters on the new line, if any, or the first column position after the last
115124 **autoindent** character, if any, or column position 1.

115125 **<control>-T**

115126 *Synopsis*: `<control>-T`

115127 The <control>-T character shall have no special meaning when in text input mode for a line-
115128 oriented command (see Command Descriptions in vi, on page 3376).

115129 This command need not be supported on block-mode terminals.

115130 Behave as if the user entered the minimum number of <blank> characters necessary to move the
115131 cursor forward to the column position after the next **shiftwidth** (see the *ex* **shiftwidth**
115132 command) boundary.

115133 *Current line*: Unchanged.

115134 *Current column*: Set to *column* + **shiftwidth** − ((column −1) % **shiftwidth**).

115135 **<control>-U**

115136 *Synopsis*: `<control>-U`

115137 If there are characters other than **autoindent** characters that have been input on the current line
115138 before the cursor, the cursor shall move to the first character input after the **autoindent**
115139 characters.

115140 Otherwise, if there are **autoindent** characters on the current line before the cursor, it is
115141 implementation-defined whether the <control>-U command is an error or if the cursor moves to
115142 the first column position on the line.

115143 Otherwise, if the cursor is in column position 1 and there are previous lines that have been
115144 input, it is implementation-defined whether the <control>-U command is an error or if it is
115145 equivalent to entering <control>-U after the last input character on the previous input line.

115146 Otherwise, it shall be an error.

115147 All of the glyphs on columns between the starting cursor position and (inclusively) the ending
115148 cursor position shall become erase-columns as described in Input Mode Commands in vi (on
115149 page 3410).

115150 The current *kill* character (see *stty*) shall cause an equivalent action to the <control>-U command,
115151 unless the previously inserted character was a <backslash>, in which case it shall be as if the
115152 literal current *kill* character had been inserted instead of the <backslash>.

115153 *Current line*: Unchanged, unless previously input lines are erased, in which case it shall be set to
115154 line −1.

115155 *Current column*: Set to the first column that displays any portion of the last character backed up
115156 over.

115157 **<control>-V**

115158 *Synopsis*: `<control>-V`
115159 `<control>-Q`

115160 Allow the entry of any subsequent character, other than <control>-J or the <newline>, as a literal
115161 character, removing any special meaning that it may have to the editor in text input mode. If a
115162 <control>-V or <control>-Q is entered before a <control>-J or <newline>, the <control>-V or
115163 <control>-Q character shall be discarded, and the <control>-J or <newline> shall behave as
115164 described in the <newline> command character during input mode.

115165 For purposes of the display only, the editor shall behave as if a `'^'` character was entered, and

the cursor shall be positioned as if overwriting the `'^'` character. When a subsequent character is entered, the editor shall behave as if that character was entered instead of the original <control>-V or <control>-Q character.

Current line: Unchanged.

Current column: Unchanged.

<control>-W

Synopsis: `<control>-W`

If there are characters other than **autoindent** characters that have been input on the current line before the cursor, the cursor shall move back over the last word preceding the cursor (including any <blank> characters between the end of the last word and the current cursor); the cursor shall not move to before the first character after the end of any **autoindent** characters.

Otherwise, if there are **autoindent** characters on the current line before the cursor, it is implementation-defined whether the <control>-W command is an error or if the cursor moves to the first column position on the line.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-W command is an error or if it is equivalent to entering <control>-W after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 3410).

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line –1.

Current column: Set to the first column that displays any portion of the last character backed up over.

<ESC>

Synopsis: `<ESC>`

If input was part of a line-oriented command:

1. If *interrupt* was entered, text input mode shall be terminated and the editor shall return to command mode. The terminal shall be alerted.
2. If <ESC> was entered, text input mode shall be terminated and the command shall continue execution with the input provided.

Otherwise, terminate text input mode and return to command mode.

Any **autoindent** characters entered on newly created lines that have no other non-<newline> characters shall be deleted.

Any leading **autoindent** and <blank> characters on newly created lines shall be rewritten to be the minimum number of <blank> characters possible.

The screen shall be redisplayed as necessary to match the contents of the edit buffer.

Current line: Unchanged.

Current column:

1. If there are text input characters on the current line, the column shall be set to the last column where any portion of the last text input character is displayed.
2. Otherwise, if a character is displayed in the current column, unchanged.
3. Otherwise, set to column position 1.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, *vi* shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered it shall be equivalent to a SIGHUP asynchronous event.

Otherwise, when an error is encountered, the editor shall behave as specified in Command Descriptions in vi (on page 3376).

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

See the RATIONALE for *ex* for more information on *vi*. Major portions of the *vi* utility specification point to *ex* to avoid inadvertent divergence. While *ex* and *vi* have historically been implemented as a single utility, this is not required by POSIX.1-2017.

It is recognized that portions of *vi* would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing, thus it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that a *vi* implementation should provide the full set of capabilities on all terminals capable of supporting them.

Historically, *vi* exited immediately if the standard input was not a terminal. POSIX.1-2017 permits, but does not require, this behavior. An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically a *vi* command.

The text in the STDOUT section reflects the usage of the verb *display* in this section; some implementations of *vi* use standard output to write to the terminal, but POSIX.1-2017 does not require that to be the case.

Historically, implementations reverted to open mode if the terminal was incapable of supporting full visual mode. POSIX.1-2017 requires this behavior. Historically, the open mode of *vi* behaved roughly equivalently to the visual mode, with the exception that only a single line from the edit buffer (one ``buffer line'') was kept current at any time. This line was normally displayed on the next-to-last line of a terminal with cursor addressing (and the last line performed its normal visual functions for line-oriented commands and messages). In addition, some few commands behaved differently in open mode than in visual mode. POSIX.1-2017 requires conformance to historical practice.

Historically, *ex* and *vi* implementations have expected text to proceed in the usual European/Latin order of left to right, top to bottom. There is no requirement in POSIX.1-2017 that this be the case. The specification was deliberately written using words like ``before'', ``after'', ``first'', and ``last'' in order to permit implementations to support the natural text order of the language.

Historically, lines past the end of the edit buffer were marked with single <tilde> (`'~'`) characters; that is, if the one-based display was 20 lines in length, and the last line of the file was on line one, then lines 2-20 would contain only a single `'~'` character.

Historically, the *vi* editor attempted to display only complete lines at the bottom of the screen (it did display partial lines at the top of the screen). If a line was too long to fit in its entirety at the bottom of the screen, the screen lines where the line would have been displayed were displayed as single `'@'` characters, instead of displaying part of the line. POSIX.1-2017 permits, but does not require, this behavior. Implementations are encouraged to attempt always to display a complete line at the bottom of the screen when doing scrolling or screen positioning by buffer lines.

Historically, lines marked with `'@'` were also used to minimize output to dumb terminals over slow lines; that is, changes local to the cursor were updated, but changes to lines on the screen that were not close to the cursor were simply marked with an `'@'` sign instead of being updated to match the current text. POSIX.1-2017 permits, but does not require this feature because it is used ever less frequently as terminals become smarter and connections are faster.

Initialization in ex and vi

Historically, *vi* always had a line in the edit buffer, even if the edit buffer was ``empty''. For example:

1. The *ex* command **=** executed from visual mode wrote ``1'' when the buffer was empty.
2. Writes from visual mode of an empty edit buffer wrote files of a single character (a <newline>), while writes from *ex* mode of an empty edit buffer wrote empty files.
3. Put and read commands into an empty edit buffer left an empty line at the top of the edit buffer.

For consistency, POSIX.1-2017 does not permit any of these behaviors.

Historically, *vi* did not always return the terminal to its original modes; for example, ICRNL was modified if it was not originally set. POSIX.1-2017 does not permit this behavior.

Command Descriptions in vi

Motion commands are among the most complicated aspects of *vi* to describe. With some exceptions, the text region and buffer type effect of a motion command on a *vi* command are described on a case-by-case basis. The descriptions of text regions in POSIX.1-2017 are not intended to imply direction; that is, an inclusive region from line *n* to line *n*+5 is identical to a region from line *n*+5 to line *n*. This is of more than academic interest—movements to marks can be in either direction, and, if the **wrapscan** option is set, so can movements to search points. Historically, lines are always stored into buffers in text order; that is, from the start of the edit buffer to the end. POSIX.1-2017 requires conformance to historical practice.

Historically, command counts were applied to any associated motion, and were multiplicative to any supplied motion count. For example, **2cw** is the same as **c2w**, and **2c3w** is the same as **c6w**. POSIX.1-2017 requires this behavior. Historically, *vi* commands that used bigwords, words, paragraphs, and sentences as objects treated groups of empty lines, or lines that contained only

115293 <blank> characters, inconsistently. Some commands treated them as a single entity, while others
115294 treated each line separately. For example, the **w**, **W**, and **B** commands treated groups of empty
115295 lines as individual words; that is, the command would move the cursor to each new empty line.
115296 The **e** and **E** commands treated groups of empty lines as a single word; that is, the first use
115297 would move past the group of lines. The **b** command would just beep at the user, or if done from
115298 the start of the line as a motion command, fail in unexpected ways. If the lines contained only (or
115299 ended with) <blank> characters, the **w** and **W** commands would just beep at the user, the **E** and
115300 **e** commands would treat the group as a single word, and the **B** and **b** commands would treat the
115301 lines as individual words. For consistency and simplicity of specification, POSIX.1-2017 requires
115302 that all *vi* commands treat groups of empty or blank lines as a single entity, and that movement
115303 through lines ending with <blank> characters be consistent with other movements.

115304 Historically, *vi* documentation indicated that any number of double-quotes were skipped after
115305 punctuation marks at sentence boundaries; however, implementations only skipped single-
115306 quotes. POSIX.1-2017 requires both to be skipped.

115307 Historically, the first and last characters in the edit buffer were word boundaries. This historical
115308 practice is required by POSIX.1-2017.

115309 Historically, *vi* attempted to update the minimum number of columns on the screen possible,
115310 which could lead to misleading information being displayed. POSIX.1-2017 makes no
115311 requirements other than that the current character being entered is displayed correctly, leaving
115312 all other decisions in this area up to the implementation.

115313 Historically, lines were arbitrarily folded between columns of any characters that required
115314 multiple column positions on the screen, with the exception of tabs, which terminated at the
115315 right-hand margin. POSIX.1-2017 permits the former and requires the latter. Implementations
115316 that do not arbitrarily break lines between columns of characters that occupy multiple column
115317 positions should not permit the cursor to rest on a column that does not contain any part of a
115318 character.

115319 The historical *vi* had a problem in that all movements were by buffer lines, not by display or
115320 screen lines. This is often the right thing to do; for example, single line movements, such as **j** or
115321 **k**, should work on buffer lines. Commands like **dj**, or **j.**, where **.** is a change command, only
115322 make sense for buffer lines. It is not, however, the right thing to do for screen motion or scrolling
115323 commands like <control>-D, <control>-F, and **H**. If the window is fairly small, using buffer lines
115324 in these cases can result in completely random motion; for example, **1**<control>**-D** can result in a
115325 completely changed screen, without any overlap. This is clearly not what the user wanted. The
115326 problem is even worse in the case of the **H**, **L**, and **M** commands ‡ás they position the cursor at
115327 the first non-<blank> of the line, they may all refer to the same location in large lines, and will
115328 result in no movement at all.

115329 In addition, if the line is larger than the screen, using buffer lines can make it impossible to
115330 display parts of the line ‡thee are not any commands that do not display the beginning of the
115331 line in historical *vi*, and if both the beginning and end of the line cannot be on the screen at the
115332 same time, the user suffers. Finally, the page and half-page scrolling commands historically
115333 moved to the first non-<blank> in the new line. If the line is approximately the same size as the
115334 screen, this is inadequate because the cursor before and after a <control>-D command will refer
115335 to the same location on the screen.

115336 Implementations of *ex* and *vi* exist that do not have these problems because the relevant
115337 commands (<control>-B, <control>-D, <control>-F, <control>-U, <control>-Y, <control>-E, **H**, **L**,
115338 and **M)** operate on display (screen) lines, not (edit) buffer lines.

115339 POSIX.1-2017 does not permit this behavior by default because the standard developers believed
115340 that users would find it too confusing. However, historical practice has been relaxed. For

example, *ex* and *vi* historically attempted, albeit sometimes unsuccessfully, to never put part of a line on the last lines of a screen; for example, if a line would not fit in its entirety, no part of the line was displayed, and the screen lines corresponding to the line contained single '@' characters. This behavior is permitted, but not required by POSIX.1-2017, so that it is possible for implementations to support long lines in small screens more reasonably without changing the commands to be oriented to the display (instead of oriented to the buffer). POSIX.1-2017 also permits implementations to refuse to edit any edit buffer containing a line that will not fit on the screen in its entirety.

The display area (for example, the value of the **window** edit option) has historically been ``grown'', or expanded, to display new text when local movements are done in displays where the number of lines displayed is less than the maximum possible. Expansion has historically been the first choice, when the target line is less than the maximum possible expansion value away. Scrolling has historically been the next choice, done when the target line is less than half a display away, and otherwise, the screen was redrawn. There were exceptions, however, in that *ex* commands generally always caused the screen to be redrawn. POSIX.1-2017 does not specify a standard behavior because there may be external issues, such as connection speed, the number of characters necessary to redraw as opposed to scroll, or terminal capabilities that implementations will have to accommodate.

The current line in POSIX.1-2017 maps one-to-one to a buffer line in the file. The current column does not. There are two different column values that are described by POSIX.1-2017. The first is the current column value as set by many of the *vi* commands. This value is remembered for the lifetime of the editor. The second column value is the actual position on the screen where the cursor rests. The two are not always the same. For example, when the cursor is backed by a multi-column character, the actual cursor position on the screen has historically been the last column of the character in command mode, and the first column of the character in input mode.

Commands that set the current line, but that do not set the current cursor value (for example, **j** and **k**) attempt to get as close as possible to the remembered column position, so that the cursor tends to restrict itself to a vertical column as the user moves around in the edit buffer. POSIX.1-2017 requires conformance to historical practice, requiring that the display location of the cursor on the display line be adjusted from the current column value as necessary to support this historical behavior.

Historically, only a single line (and for some terminals, a single line minus 1 column) of characters could be entered by the user for the line-oriented commands; that is, **:**, **!**, **/**, or **?**. POSIX.1-2017 permits, but does not require, this limitation.

Historically, ``soft'' errors in *vi* caused the terminal to be alerted, but no error message was displayed. As a general rule, no error message was displayed for errors in command execution in *vi*, when the error resulted from the user attempting an invalid or impossible action, or when a searched-for object was not found. Examples of soft errors included **h** at the left margin, <control>-B or **[[** at the beginning of the file, **2G** at the end of the file, and so on. In addition, errors such as **%**, **]]**, **}**, **)**, **N**, **n**, **f**, **F**, **t**, and **T** failing to find the searched-for object were soft as well. Less consistently, **/** and **?** displayed an error message if the pattern was not found, **/**, **?**, **N**, and **n** displayed an error message if no previous regular expression had been specified, and **;** did not display an error message if no previous **f**, **F**, **t**, or **T** command had occurred. Also, behavior in this area might reasonably be based on a runtime evaluation of the speed of a network connection. Finally, some implementations have provided error messages for soft errors in order to assist naive users, based on the value of a verbose edit option. POSIX.1-2017 does not list specific errors for which an error message shall be displayed. Implementations should conform to historical practice in the absence of any strong reason to diverge.

115389 **Page Backwards**

115390 The <control>-B and <control>-F commands historically considered it an error to attempt to
115391 page past the beginning or end of the file, whereas the <control>-D and <control>-U commands
115392 simply moved to the beginning or end of the file. For consistency, POSIX.1-2017 requires the
115393 latter behavior for all four commands. All four commands still consider it an error if the current
115394 line is at the beginning (<control>-B, <control>-U) or end (<control>-F, <control>-D) of the file.
115395 Historically, the <control>-B and <control>-F commands skip two lines in order to include
115396 overlapping lines when a single command is entered. This makes less sense in the presence of a
115397 *count*, as there will be, by definition, no overlapping lines. The actual calculation used by
115398 historical implementations of the *vi* editor for <control>-B was:

115399 `((current first line) − count x (window edit option)) +2`

115400 and for <control>-F was:

115401 `((current first line) + count x (window edit option)) −2`

115402 This calculation does not work well when intermixing commands with and without counts; for
115403 example, **3<control>-F is not equivalent to entering the <control>-F command three times,**
115404 **and is not reversible by entering the <control>-B command three times. For consistency with**
115405 **other *vi* commands that take counts, POSIX.1-2017 requires a different calculation.**

115406 **Scroll Forward**

115407 The 4BSD and System V implementations of *vi* differed on the initial value used by the **scroll**
115408 command. 4BSD used:

115409 `((window edit option) +1) /2`

115410 while System V used the value of the **scroll** edit option. The System V version is specified by
115411 POSIX.1-2017 because the standard developers believed that it was more intuitive and permitted
115412 the user a method of setting the scroll value initially without also setting the number of lines that
115413 are displayed.

115414 **Scroll Forward by Line**

115415 Historically, the <control>-E and <control>-Y commands considered it an error if the last and
115416 first lines, respectively, were already on the screen. POSIX.1-2017 requires conformance to
115417 historical practice. Historically, the <control>-E and <control>-Y commands had no effect in
115418 open mode. For simplicity and consistency of specification, POSIX.1-2017 requires that they
115419 behave as usual, albeit with a single line screen.

115420 **Clear and Redisplay**

115421 The historical <control>-L command refreshed the screen exactly as it was supposed to be
115422 currently displayed, replacing any `'@'` characters for lines that had been deleted but not
115423 updated on the screen with refreshed `'@'` characters. The intent of the <control>-L command is
115424 to refresh when the screen has been accidentally overwritten; for example, by a **write** command
115425 from another user, or modem noise.

Redraw Screen

The historical <control>-R command redisplayed only when necessary to update lines that had been deleted but not updated on the screen and that were flagged with `'@'` characters. There is no requirement that the screen be in any way refreshed if no lines of this form are currently displayed. POSIX.1-2017 permits implementations to extend this command to refresh lines on the screen flagged with `'@'` characters because they are too long to be displayed in the current framework; however, the current line and column need not be modified.

Search for tagstring

Historically, the first non-<blank> at or after the cursor was the first character, and all subsequent characters that were word characters, up to the end of the line, were included. For example, with the cursor on the leading <space> or on the `'#'` character in the text `"#bar@"`, the tag was `"#bar"`. On the character `'b'` it was `"bar"`, and on the `'a'` it was `"ar"`. POSIX.1-2017 requires this behavior.

Replace Text with Results from Shell Command

Historically, the **<**, **>**, and **!** commands considered most cursor motions other than line-oriented motions an error; for example, the command **>/foo<CR>** succeeded, while the command **>l** failed, even though the text region described by the two commands might be identical. For consistency, all three commands only consider entire lines and not partial lines, and the region is defined as any line that contains a character that was specified by the motion.

Move to Matching Character

Other matching characters have been left implementation-defined in order to allow extensions such as matching `'<'` and `'>'` for searching HTML, or **#ifdef**, **#else**, and **#endif** for searching C source.

Repeat Substitution

POSIX.1-2017 requires that any **c** and **g** flags specified to the previous substitute command be ignored; however, the **r** flag may still apply, if supported by the implementation.

Return to Previous (Context or Section)

The **[[**, **]]**, **(**, **)**, **{**, and **}** commands are all affected by ``section boundaries'', but in some historical implementations not all of the commands recognize the same section boundaries. This is a bug, not a feature, and a unique section-boundary algorithm was not described for each command. One special case that is preserved is that the sentence command moves to the end of the last line of the edit buffer while the other commands go to the beginning, in order to preserve the traditional character cut semantics of the sentence command. Historically, *vi* section boundaries at the beginning and end of the edit buffer were the first non-<blank> on the first and last lines of the edit buffer if one exists; otherwise, the last character of the first and last lines of the edit buffer if one exists. To increase consistency with other section locations, this has been simplified by POSIX.1-2017 to the first character of the first and last lines of the edit buffer, or the first and the last lines of the edit buffer if they are empty.

Sentence boundaries were problematic in the historical *vi*. They were not only the boundaries as defined for the section and paragraph commands, but they were the first non-<blank> that occurred after those boundaries, as well. Historically, the *vi* section commands were documented as taking an optional window size as a *count* preceding the command. This was not implemented in historical versions, so POSIX.1-2017 requires that the *count* repeat the command,

for consistency with other *vi* commands.

Repeat

Historically, mapped commands other than text input commands could not be repeated using the **period** command. POSIX.1-2017 requires conformance to historical practice.

The restrictions on the interpretation of special characters (for example, <control>-H) in the repetition of text input mode commands is intended to match historical practice. For example, given the input sequence:

```
iab<control>-H<control>-H<control>-Hdef<escape>
```

the user should be informed of an error when the sequence is first entered, but not during a command repetition. The character <control>-T is specifically exempted from this restriction. Historical implementations of *vi* ignored <control>-T characters that were input in the original command during command repetition. POSIX.1-2017 prohibits this behavior.

Find Regular Expression

Historically, commands did not affect the line searched to or from if the motion command was a search (**/**, **?**, **N**, **n**) and the final position was the start/end of the line. There were some special cases and *vi* was not consistent. POSIX.1-2017 does not permit this behavior, for consistency. Historical implementations permitted but were unable to handle searches as motion commands that wrapped (that is, due to the edit option **wrapscan**) to the original location. POSIX.1-2017 requires that this behavior be treated as an error.

Historically, the syntax `"/RE/0"` was used to force the command to cut text in line mode. POSIX.1-2017 requires conformance to historical practice.

Historically, in open mode, a **z** specified to a search command redisplayed the current line instead of displaying the current screen with the current line highlighted. For consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior.

Historically, trailing **z** commands were permitted and ignored if entered as part of a search used as a motion command. For consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior.

Execute an ex Command

Historically, *vi* implementations restricted the commands that could be entered on the colon command line (for example, **append** and **change**), and some other commands were known to cause them to fail catastrophically. For consistency, POSIX.1-2017 does not permit these restrictions. When executing an *ex* command by entering **:**, it is not possible to enter a <newline> as part of the command because it is considered the end of the command. A different approach is to enter *ex* command mode by using the *vi* **Q** command (and later resuming visual mode with the *ex* **vi** command). In *ex* command mode, the single-line limitation does not exist. So, for example, the following is valid:

```
Q
s/break here/break\
here/
vi
```

POSIX.1-2017 requires that, if the *ex* command overwrites any part of the screen that would be erased by a refresh, *vi* pauses for a character from the user. Historically, this character could be any character; for example, a character input by the user before the message appeared, or even a

115512 mapped character. This is probably a bug, but implementations that have tried to be more
115513 rigorous by requiring that the user enter a specific character, or that the user enter a character
115514 after the message was displayed, have been forced by user indignation back into historical
115515 behavior. POSIX.1-2017 requires conformance to historical practice.

115516 **Shift Left (Right)**

115517 Refer to the Rationale for the **!** and **/** commands. Historically, the **<** and **>** commands sometimes
115518 moved the cursor to the first non-<blank> (for example if the command was repeated or with _
115519 as the motion command), and sometimes left it unchanged. POSIX.1-2017 does not permit this
115520 inconsistency, requiring instead that the cursor always move to the first non-<blank>.
115521 Historically, the **<** and **>** commands did not support buffer arguments, although some
115522 implementations allow the specification of an optional buffer. This behavior is neither required
115523 nor disallowed by POSIX.1-2017.

115524 **Execute**

115525 Historically, buffers could execute other buffers, and loops, infinite and otherwise, were
115526 possible. POSIX.1-2017 requires conformance to historical practice. The **buffer* syntax of *ex* is not
115527 required in *vi*, because it is not historical practice and has been used in some *vi* implementations
115528 to support additional scripting languages.

115529 **Reverse Case**

115530 Historically, the ~ command ignored any associated *count*, and acted only on the characters in the
115531 current line. For consistency with other *vi* commands, POSIX.1-2017 requires that an associated
115532 *count* act on the next *count* characters, and that the command move to subsequent lines if
115533 warranted by *count*, to make it possible to modify large pieces of text in a reasonably efficient
115534 manner. There exist *vi* implementations that optionally require an associated motion command
115535 for the ~ command. Implementations supporting this functionality are encouraged to base it on
115536 the **tildedop** edit option and handle the text regions and cursor positioning identically to the
115537 **yank** command.

115538 **Append**

115539 Historically, *count*s specified to the **A**, **a**, **I**, and **i** commands repeated the input of the first line
115540 *count* times, and did not repeat the subsequent lines of the input text. POSIX.1-2017 requires that
115541 the entire text input be repeated *count* times.

115542 **Move Backward to Preceding Word**

115543 Historically, *vi* became confused if word commands were used as motion commands in empty
115544 files. POSIX.1-2017 requires that this be an error. Historical implementations of *vi* had a large
115545 number of bugs in the word movement commands, and they varied greatly in behavior in the
115546 presence of empty lines, ``words'' made up of a single character, and lines containing only
115547 <blank> characters. For consistency and simplicity of specification, POSIX.1-2017 does not
115548 permit this behavior.

115549 **Change to End-of-Line**

115550 Some historical implementations of the **C** command did not behave as described by
115551 POSIX.1-2017 when the **$** key was remapped because they were implemented by pushing the **$**
115552 key onto the input queue and reprocessing it. POSIX.1-2017 does not permit this behavior.
115553 Historically, the **C**, **S**, and **s** commands did not copy replaced text into the numeric buffers. For
115554 consistency and simplicity of specification, POSIX.1-2017 requires that they behave like their
115555 respective **c** commands in all respects.

115556 **Delete**

115557 Historically, lines in open mode that were deleted were scrolled up, and an @ glyph written over
115558 the beginning of the line. In the case of terminals that are incapable of the necessary cursor
115559 motions, the editor erased the deleted line from the screen. POSIX.1-2017 requires conformance
115560 to historical practice; that is, if the terminal cannot display the `'@'` character, the line cannot
115561 remain on the screen.

115562 **Delete to End-of-Line**

115563 Some historical implementations of the **D** command did not behave as described by
115564 POSIX.1-2017 when the **$** key was remapped because they were implemented by pushing the **$**
115565 key onto the input queue and reprocessing it. POSIX.1-2017 does not permit this behavior.

115566 **Join**

115567 An historical oddity of *vi* is that the commands **J**, **1J**, and **2J** are all equivalent. POSIX.1-2017
115568 requires conformance to historical practice. The *vi* **J** command is specified in terms of the *ex* **join**
115569 command with an *ex* command *count* value. The address correction for a *count* that is past the
115570 end of the edit buffer is necessary for historical compatibility for both *ex* and *vi*.

115571 **Mark Position**

115572 Historical practice is that only lowercase letters, plus backquote and single-quote, could be used
115573 to mark a cursor position. POSIX.1-2017 requires conformance to historical practice, but
115574 encourages implementations to support other characters as marks as well.

115575 **Repeat Regular Expression Find (Forward and Reverse)**

115576 Historically, the **N** and **n** commands could not be used as motion components for the **c**
115577 command. With the exception of the **cN** command, which worked if the search crossed a line
115578 boundary, the text region would be discarded, and the user would not be in text input mode. For
115579 consistency and simplicity of specification, POSIX.1-2017 does not permit this behavior.

115580 **Insert Empty Line (Below and Above)**

115581 Historically, counts to the **O** and **o** commands were used as the number of physical lines to
115582 open, if the terminal was dumb and the **slowopen** option was not set. This was intended to
115583 minimize traffic over slow connections and repainting for dumb terminals. POSIX.1-2017 does
115584 not permit this behavior, requiring that a *count* to the open command behave as for other text
115585 input commands. This change to historical practice was made for consistency, and because a
115586 superset of the functionality is provided by the **slowopen** edit option.

115587 **Put from Buffer (Following and Before)**

115588 Historically, *count*s to the **p** and **P** commands were ignored if the buffer was a line mode buffer,
115589 but were (mostly) implemented as described in POSIX.1-2017 if the buffer was a character mode
115590 buffer. Because implementations exist that do not have this limitation, and because pasting lines
115591 multiple times is generally useful, POSIX.1-2017 requires that *count* be supported for all **p** and **P**
115592 commands.

115593 Historical implementations of *vi* were widely known to have major problems in the **p** and **P**
115594 commands, particularly when unusual regions of text were copied into the edit buffer. The
115595 standard developers viewed these as bugs, and they are not permitted for consistency and
115596 simplicity of specification.

115597 Historically, a **P** or **p** command (or an *ex* **put** command executed from open or visual mode)
115598 executed in an empty file, left an empty line as the first line of the file. For consistency and
115599 simplicity of specification, POSIX.1-2017 does not permit this behavior.

115600 **Replace Character**

115601 Historically, the **r** command did not correctly handle the *erase* and *word erase* characters as
115602 arguments, nor did it handle an associated *count* greater than 1 with a <carriage-return>
115603 argument, for which it replaced *count* characters with a single <newline>. POSIX.1-2017 does
115604 not permit these inconsistencies.

115605 Historically, the **r** command permitted the <control>-V escaping of entered characters, such as
115606 <ESC> and the <carriage-return>; however, it required two leading <control>-V characters
115607 instead of one. POSIX.1-2017 requires that this be changed for consistency with the other text
115608 input commands of *vi*.

115609 Historically, it is an error to enter the **r** command if there are less than *count* characters at or after
115610 the cursor in the line. While a reasonable and unambiguous extension would be to permit the **r**
115611 command on empty lines, it would require that too large a *count* be adjusted to match the
115612 number of characters at or after the cursor for consistency, which is sufficiently different from
115613 historical practice to be avoided. POSIX.1-2017 requires conformance to historical practice.

115614 **Replace Characters**

115615 Historically, if there were **autoindent** characters in the line on which the **R** command was run,
115616 and **autoindent** was set, the first <newline> would be properly indented and no characters
115617 would be replaced by the <newline>. Each additional <newline> would replace *n* characters,
115618 where *n* was the number of characters that were needed to indent the rest of the line to the
115619 proper indentation level. This behavior is a bug and is not permitted by POSIX.1-2017.

115620 **Undo**

115621 Historical practice for cursor positioning after undoing commands was mixed. In most cases,
115622 when undoing commands that affected a single line, the cursor was moved to the start of added
115623 or changed text, or immediately after deleted text. However, if the user had moved from the line
115624 being changed, the column was either set to the first non-<blank>, returned to the origin of the
115625 command, or remained unchanged. When undoing commands that affected multiple lines or
115626 entire lines, the cursor was moved to the first character in the first line restored. As an example
115627 of how inconsistent this was, a search, followed by an **o** text input command, followed by an
115628 **undo** would return the cursor to the location where the **o** command was entered, but a **cw**
115629 command followed by an **o** command followed by an **undo** would return the cursor to the first
115630 non-<blank> of the line. POSIX.1-2017 requires the most useful of these behaviors, and discards
115631 the least useful, in the interest of consistency and simplicity of specification.

115632 **Yank**

115633 Historically, the **yank** command did not move to the end of the motion if the motion was in the
115634 forward direction. It moved to the end of the motion if the motion was in the backward
115635 direction, except for the _ command, or for the **G** and **'** commands when the end of the motion
115636 was on the current line. This was further complicated by the fact that for a number of motion
115637 commands, the **yank** command moved the cursor but did not update the screen; for example, a
115638 subsequent command would move the cursor from the end of the motion, even though the
115639 cursor on the screen had not reflected the cursor movement for the **yank** command.
115640 POSIX.1-2017 requires that all **yank** commands associated with backward motions move the
115641 cursor to the end of the motion for consistency, and specifically, to make **'** commands as motions
115642 consistent with search patterns as motions.

115643 **Yank Current Line**

115644 Some historical implementations of the **Y** command did not behave as described by
115645 POSIX.1-2017 when the `'_'` key was remapped because they were implemented by pushing the
115646 `'_'` key onto the input queue and reprocessing it. POSIX.1-2017 does not permit this behavior.

115647 **Redraw Window**

115648 Historically, the **z** command always redrew the screen. This is permitted but not required by
115649 POSIX.1-2017, because of the frequent use of the **z** command in macros such as **map n nz.** for
115650 screen positioning, instead of its use to change the screen size. The standard developers
115651 believed that expanding or scrolling the screen offered a better interface for users. The ability to
115652 redraw the screen is preserved if the optional new window size is specified, and in the
115653 <control>-L and <control>-R commands.

115654 The semantics of **z^** are confusing at best. Historical practice is that the screen before the screen
115655 that ended with the specified line is displayed. POSIX.1-2017 requires conformance to historical
115656 practice.

115657 Historically, the **z** command would not display a partial line at the top or bottom of the screen. If
115658 the partial line would normally have been displayed at the bottom of the screen, the command
115659 worked, but the partial line was replaced with `'@'` characters. If the partial line would normally
115660 have been displayed at the top of the screen, the command would fail. For consistency and
115661 simplicity of specification, POSIX.1-2017 does not permit this behavior.

115662 Historically, the **z** command with a line specification of 1 ignored the command. For consistency
115663 and simplicity of specification, POSIX.1-2017 does not permit this behavior.

115664 Historically, the **z** command did not set the cursor column to the first non-<blank> for the
115665 character if the first screen was to be displayed, and was already displayed. For consistency and
115666 simplicity of specification, POSIX.1-2017 does not permit this behavior.

115667 **Input Mode Commands in vi**

115668 Historical implementations of *vi* did not permit the user to erase more than a single line of input,
115669 or to use normal erase characters such as *line erase*, *worderase*, and *erase* to erase **autoindent**
115670 characters. As there exist implementations of *vi* that do not have these limitations, both
115671 behaviors are permitted, but only historical practice is required. In the case of these extensions,
115672 *vi* is required to pause at the **autoindent** and previous line boundaries.

115673 Historical implementations of *vi* updated only the portion of the screen where the current cursor
115674 character was displayed. For example, consider the *vi* input keystrokes:

115675 `iabcd<escape>0C<tab>`

Historically, the <tab> would overwrite the characters "abcd" when it was displayed. Other implementations replace only the 'a' character with the <tab>, and then push the rest of the characters ahead of the cursor. Both implementations have problems. The historical implementation is probably visually nicer for the above example; however, for the keystrokes:

```
iabcd<ESC>0R<tab><ESC>
```

the historical implementation results in the string "bcd" disappearing and then magically reappearing when the <ESC> character is entered. POSIX.1-2017 requires the former behavior when overwriting erase-columns ‡that is, overwriting characters that are no longer logically part of the edit buffer—and the latter behavior otherwise.

Historical implementations of *vi* discarded the <control>-D and <control>-T characters when they were entered at places where their command functionality was not appropriate. POSIX.1-2017 requires that the <control>-T functionality always be available, and that <control>-D be treated as any other key when not operating on **autoindent** characters.

NUL

Some historical implementations of *vi* limited the number of characters entered using the NUL input character to 256 bytes. POSIX.1-2017 permits this limitation; however, implementations are encouraged to remove this limit.

<control>-D

See also Rationale for the input mode command <newline>. The hidden assumptions in the <control>-D command (and in the *vi* **autoindent** specification in general) is that <space> characters take up a single column on the screen and that <tab> characters are comprised of an integral number of <space> characters.

<newline>

Implementations are permitted to rewrite **autoindent** characters in the line when <newline>, <carriage-return>, <control>-D, and <control>-T are entered, or when the **shift** commands are used, because historical implementations have both done so and found it necessary to do so. For example, a <control>-D when the cursor is preceded by a single <tab>, with **tabstop** set to 8, and **shiftwidth** set to 3, will result in the <tab> being replaced by several <space> characters.

<control>-T

See also the Rationale for the input mode command <newline>. Historically, <control>-T only worked if no non-<blank> characters had yet been input in the current input line. In addition, the characters inserted by <control>-T were treated as **autoindent** characters, and could not be erased using normal user erase characters. Because implementations exist that do not have these limitations, and as moving to a column boundary is generally useful, POSIX.1-2017 requires that both limitations be removed.

115711 **<control>-V**

115712 Historically, *vi* used **^V**, regardless of the value of the literal-next character of the terminal.
115713 POSIX.1-2017 requires conformance to historical practice.

115714 The uses described for <control>-V can also be accomplished with <control>-Q, which is useful
115715 on terminals that use <control>-V for the down-arrow function. However, most historical
115716 implementations use <control>-Q for the *termios* START character, so the editor will generally
115717 not receive the <control>-Q unless **stty ixon** mode is set to off. (In addition, some historical
115718 implementations of *vi* explicitly set **ixon** mode to on, so it was difficult for the user to set it to
115719 off.) Any of the command characters described in POSIX.1-2017 can be made ineffective by their
115720 selection as *termios* control characters, using the *stty* utility or other methods described in the
115721 System Interfaces volume of POSIX.1-2017.

115722 **<ESC>**

115723 Historically, SIGINT alerted the terminal when used to end input mode. This behavior is
115724 permitted, but not required, by POSIX.1-2017.

115725 **FUTURE DIRECTIONS**

115726 None.

115727 **SEE ALSO**

115728 *ed*, *ex*, *stty*

115729 XBD Section 12.2 (on page 216)

115730 **CHANGE HISTORY**

115731 First released in Issue 2.

115732 **Issue 5**

115733 The FUTURE DIRECTIONS section is added.

115734 **Issue 6**

115735 This utility is marked as part of the User Portability Utilities option.

115736 The APPLICATION USAGE section is added.

115737 The obsolescent SYNOPSIS is removed.

115738 The following new requirements on POSIX implementations derive from alignment with the
115739 Single UNIX Specification:

115740 — The **reindent** command description is added.

115741 The *vi* utility has been extensively rewritten for alignment with the IEEE P1003.2b draft
115742 standard.

115743 IEEE PASC Interpretations 1003.2 #57, #62, #63, #64, #78, and #188 are applied.

115744 IEEE PASC Interpretation 1003.2 #207 is applied, clarifying the description of the **R** command in
115745 a manner similar to the descriptions of other text input mode commands such as **i**, **o**, and **O**.

115746 The **–l** option is removed.

115747 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/41 is applied, adding [*count*] to the
115748 Synopsis for **[[**.

115749 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/42 is applied, adding [*count*] to the
115750 Synopsis for **]]**.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that `'+'` may be recognized as an option delimiter in the OPTIONS section.

Austin Group Interpretation 1003.1-2001 #087 is applied, updating the Put from Buffer Before (**P**) command description to address multi-line requirements.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0202 [812] is applied.

NAME

wait — await process completion

SYNOPSIS

```
wait [pid...]
```

DESCRIPTION

When an asynchronous list (see Section 2.9.3.1, on page 2370) is started by the shell, the process ID of the last command in each element of the asynchronous list shall become known in the current shell execution environment; see Section 2.12 (on page 2381).

If the *wait* utility is invoked with no operands, it shall wait until all process IDs known to the invoking shell have terminated and exit with a zero exit status.

If one or more *pid* operands are specified that represent known process IDs, the *wait* utility shall wait until all of them have terminated. If one or more *pid* operands are specified that represent unknown process IDs, *wait* shall treat them as if they were known process IDs that exited with exit status 127. The exit status returned by the *wait* utility shall be the exit status of the process requested by the last *pid* operand.

The known process IDs are applicable only for invocations of *wait* in the current shell execution environment.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

pid One of the following:

1. The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.
2. A job control job ID (see XBD Section 3.204, on page 66) that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of *wait* in the current shell execution environment; see Section 2.12 (on page 2381). The exit status of *wait* shall be determined by the last command in the pipeline.

   Note: The job control job ID type of *pid* is only available on systems supporting the User Portability Utilities option.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *wait*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If one or more operands were specified, all of them have terminated or were not known by the invoking shell, and the status of the last operand specified is known, then the exit status of *wait* shall be the exit status information of the command indicated by the last operand specified. If the process terminated abnormally due to the receipt of a signal, the exit status shall be greater than 128 and shall be distinct from the exit status generated by other signals, but the exact value is unspecified. (See the *kill* **–l** option.) Otherwise, the *wait* utility shall exit with one of the following values:

0 The *wait* utility was invoked with no operands and all process IDs known by the invoking shell have terminated.

1-126 The *wait* utility detected an error.

127 The command identified by the last *pid* operand specified is unknown.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

On most implementations, *wait* is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(wait)
nohup wait ...
find . –exec wait ... \;
```

it returns immediately because there are no known process IDs to wait for in those environments.

Historical implementations of interactive shells have discarded the exit status of terminated background processes before each shell prompt. Therefore, the status of background processes was usually lost unless it terminated while *wait* was waiting for it. This could be a serious problem when a job that was expected to run for a long time actually terminated quickly with a syntax or initialization error because the exit status returned was usually zero if the requested

process ID was not found. This volume of POSIX.1-2017 requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

```
j1&
p1=$!
j2&
wait $p1
echo Job 1 exited with status $?
wait $!
echo Job 2 exited with status $?
```

work without losing status on any of the jobs. The shell is allowed to discard the status of any process if it determines that the application cannot get the process ID for that process from the shell. It is also required to remember only {CHILD_MAX} number of processes in this way. Since the only way to get the process ID from the shell is by using the `'!'` shell parameter, the shell is allowed to discard the status of an asynchronous list if `"$!"` was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference `"$!"`. If the implementation of the shell is smart enough to determine that a reference to `"$!"` was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to *wait* with no operands discards the exit status of all asynchronous lists.)

If the exit status of *wait* is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.

EXAMPLES

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably determine which signal by using *kill* as shown by the following script:

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l $?) signal.
```

If the following sequence of commands is run in less than 31 seconds:

```
sleep 257 | sleep 31 &
jobs -l %%
```

either of the following commands returns the exit status of the second *sleep* in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

RATIONALE

The description of *wait* does not refer to the *waitpid*() function from the System Interfaces volume of POSIX.1-2017 because that would needlessly overspecify this interface. However, the wording means that *wait* is required to wait for an explicit process when it is given an argument so that the status information of other processes is not consumed. Historical implementations use the *wait*() function defined in the System Interfaces volume of POSIX.1-2017 until *wait*() returns the requested process ID or finds that the requested process does not exist. Because this

means that a shell script could not reliably get the status of all background children if a second background job was ever started before the first job finished, it is recommended that the *wait* utility use a method such as the functionality provided by the *waitpid*( ) function.

The ability to wait for multiple *pid* operands was adopted from the KornShell.

This new functionality was added because it is needed to determine the exit status of any asynchronous list accurately. The only compatibility problem that this change creates is for a script like

```
while sleep 60 do
    job& echo Job started $(date) as $!  done
```

which causes the shell to monitor all of the jobs started until the script terminates or runs out of memory. This would not be a problem if the loop did not reference `"$!"` or if the script would occasionally *wait* for jobs it started.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

wc — word, line, and byte or character count

SYNOPSIS

```
wc [-c|-m] [-lw] [file...]
```

DESCRIPTION

The *wc* utility shall read one or more input files and, by default, write the number of <newline> characters, words, and bytes contained in each input file to the standard output.

The utility also shall write a total count for all named files, if more than one input file is specified.

The *wc* utility shall consider a *word* to be a non-zero-length string of characters delimited by white space.

OPTIONS

The *wc* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

-c Write to the standard output the number of bytes in each input file.

-l Write to the standard output the number of <newline> characters in each input file.

-m Write to the standard output the number of characters in each input file.

-w Write to the standard output the number of words in each input file.

When any option is specified, *wc* shall report only the information requested by the specified options.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files may be of any type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *wc*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as white-space characters.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

By default, the standard output shall contain an entry for each input file of the form:

`"%d %d %d %s\n", <newlines>, <words>, <bytes>, <file>`

If the **−m** option is specified, the number of characters shall replace the <*bytes*> field in this format.

If any options are specified and the **−l** option is not specified, the number of <newline> characters shall not be written.

If any options are specified and the **−w** option is not specified, the number of words shall not be written.

If any options are specified and neither **−c** nor **−m** is specified, the number of bytes or characters shall not be written.

If no input *file* operands are specified, no name shall be written and no <blank> characters preceding the pathname shall be written.

If more than one input *file* operand is specified, an additional line shall be written, of the same format as the other lines, except that the word **total** (in the POSIX locale) shall be written instead of a pathname and the total of each column shall be written as appropriate. Such an additional line, if any, is written at the end of the output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **−m** option is not a switch, but an option at the same level as **−c**. Thus, to produce the full default output with character counts instead of bytes, the command required is:

```
wc −mlw
```

EXAMPLES

None.

RATIONALE

The output file format pseudo-*printf*( ) string differs from the System V version of *wc*:

```
"%7d%7d%7d %s\n"
```

which produces possibly ambiguous and unparsable results for very large files, as it assumes no number shall exceed six digits.

Some historical implementations use only <space>, <tab>, and <newline> as word separators. The equivalent of the ISO C standard *isspace*( ) function is more appropriate.

The **−c** option stands for ``character'' count, even though it counts bytes. This stems from the sometimes erroneous historical view that bytes and characters are the same size. Due to international requirements, the **−m** option (reminiscent of ``multi-byte'') was added to obtain actual character counts.

Early proposals only specified the results when input files were text files. The current specification more closely matches historical practice. (Bytes, words, and <newline> characters are counted separately and the results are written when an end-of-file is detected.)

Historical implementations of the *wc* utility only accepted one argument to specify the options **−c**, **−l**, and **−w**. Some of them also had multiple occurrences of an option cause the corresponding count to be written multiple times and had the order of specification of the options affect the order of the fields on output, but did not document either of these. Because common usage either specifies no options or only one option, and because none of this was documented, the changes required by this volume of POSIX.1-2017 should not break many historical applications (and do not break any historical conforming applications).

FUTURE DIRECTIONS

None.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

what ‡'identify SCCS files' (**DEVELOPMENT**)

SYNOPSIS

XSI

```
what [-s] file...
```

DESCRIPTION

The *what* utility shall search the given files for all occurrences of the pattern that *get* (see *get*) substitutes for the %**Z**% keyword (`"@(#)"`) and shall write to standard output what follows until the first occurrence of one of the following:

`"` `>` `newline` `\` `NUL`

OPTIONS

The *what* utility shall conform to XBD Section 12.2 (on page 216).

The following option shall be supported:

-s Quit after finding the first occurrence of the pattern in each file.

OPERANDS

The following operands shall be supported:

file A pathname of a file to search.

STDIN

Not used.

INPUT FILES

The input files shall be of any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *what*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall consist of the following for each *file* operand:

`"%s:\n\t%s\n", <pathname>, <identification string>`

116065 **STDERR**

116066 The standard error shall be used only for diagnostic messages.

116067 **OUTPUT FILES**

116068 None.

116069 **EXTENDED DESCRIPTION**

116070 None.

116071 **EXIT STATUS**

116072 The following exit values shall be returned:

116073 0 Any matches were found.

116074 1 Otherwise.

116075 **CONSEQUENCES OF ERRORS**

116076 Default.

116077 **APPLICATION USAGE**

116078 The *what* utility is intended to be used in conjunction with the SCCS command *get*, which
116079 automatically inserts identifying information, but it can also be used where the information is
116080 inserted by any other means.

116081 When the string `"@(#)"` is included in a library routine in a shared library, it might not be found
116082 in an **a.out** file using that library routine.

116083 **EXAMPLES**

116084 If the C-language program in file **f.c** contains:

116085
```
char ident[] = "@(#)identification information";
```

116086 and **f.c** is compiled to yield **f.o** and **a.out**, then the command:

116087
```
what f.c f.o a.out
```

116088 writes:

116089
```
f.c:
    identification information
    ...
f.o:
    identification information
    ...
a.out:
    identification information
    ...
```

116098 **RATIONALE**

116099 None.

116100 **FUTURE DIRECTIONS**

116101 None.

NAME

who ‡'display who is on the system

SYNOPSIS

XSI `who [–mTu] [–abdHlprt] [file]`

XSI
```
who [–mu] –s [–bHlprt] [file]
who –q [file]
who am i
who am I
```

DESCRIPTION

The *who* utility shall list various pieces of information about accessible users. The domain of accessibility is implementation-defined.

XSI Based on the options given, *who* can also list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process ID of the command interpreter for each current system user.

OPTIONS

The *who* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported. The metavariables, such as <*line*>, refer to fields described in the STDOUT section.

XSI **–a** Process the implementation-defined database or named file with the **–b**, **–d**, **–l**, **–p**, **–r**, **–t**, **–T** and **–u** options turned on.

XSI **–b** Write the time and date of the last system reboot. The system reboot time is the time at which the implementation is able to commence running processes.

XSI **–d** Write a list of all processes that have expired and not been respawned by the *init* system process. The <*exit*> field shall appear for dead processes and contain the termination and exit values of the dead process. This can be useful in determining why a process terminated.

XSI **–H** Write column headings above the regular output.

XSI **–l** (The letter ell.) List only those lines on which the system is waiting for someone to login. The <*name*> field shall be **LOGIN** in such cases. Other fields shall be the same as for user entries except that the <*state*> field does not exist.

–m Output only information about the current terminal.

XSI **–p** List any other process that is currently active and has been previously spawned by *init*.

XSI **–q** (Quick.) List only the names and the number of users currently logged on. When this option is used, all other options shall be ignored.

XSI **–r** Write the current *run-level* of the *init* process.

XSI **–s** List only the <*name*>, <*line*>, and <*time*> fields. This is the default case.

XSI **–t** Indicate the last change to the system clock.

–T Show the state of each terminal, as described in the STDOUT section.

−u Write ``idle time'' for each displayed user in addition to any other information. The idle time is the time since any activity occurred on the user's terminal. The method of determining this is unspecified. XSI This option shall list only those users who are currently logged in. The <*name*> is the user's login name. The <*line*> is the name of the line as found in the directory **/dev**. The <*time*> is the time that the user logged in. The <*activity*> is the number of hours and minutes since activity last occurred on that particular line. A dot indicates that the terminal has seen activity in the last minute and is therefore ``current''. If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry shall be marked <*old*>. This field is useful when trying to determine whether a person is working at the terminal or not. The <*pid*> is the process ID of the user's login process.

OPERANDS

XSI The following operands shall be supported:

am i, **am I** In the POSIX locale, limit the output to describing the invoking user, equivalent to the **−m** option. The **am** and **i** or **I** must be separate arguments.

file Specify a pathname of a file to substitute for the implementation-defined database of logged-on users that *who* uses by default.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *who*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the locale used for the format and contents of the date and time strings.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone used when writing date and time information. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *who* utility shall write its default format to the standard output in an implementation-defined format, subject only to the requirement of containing the information described above.

XSI OF XSI-conformant systems shall write the default information to the standard output in the following general format:

`<name>[<state>]<line><time>[<activity>][<pid>][<comment>][<exit>]`

For the **–b** option, <*line*> shall be `"system boot"`. The <*name*> is unspecified.

The following format shall be used for the **–T** option:

```
"%s %c %s %s\n" <name>, <terminal state>, <terminal name>,
    <time of login>
```

where <*terminal state*> is one of the following characters:

`+` The terminal allows write access to other users.

`–` The terminal denies write access to other users.

`?` The terminal write-access state cannot be determined.

`<space>` This entry is not associated with a terminal.

In the POSIX locale, the <*time of login*> shall be equivalent in format to the output of:

```
date +"%b %e %H:%M"
```

If the **–u** option is used with **–T**, the idle time shall be added to the end of the previous format in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The name *init* used for the system process is the most commonly used on historical systems, but it may vary.

The ``domain of accessibility'' referred to is a broad concept that permits interpretation either on a very secure basis or even to allow a network-wide implementation like the historical *rwho*.

EXAMPLES

None.

RATIONALE

Due to differences between historical implementations, the base options provided were a compromise to allow users to work with those functions. The standard developers also considered removing all the options, but felt that these options offered users valuable functionality. Additional options to match historical systems are available on XSI-conformant

systems.

It is recognized that the *who* command may be of limited usefulness, especially in a multi-level secure environment. The standard developers considered, however, that having some standard method of determining the ``accessibility'' of other users would aid user portability.

No format was specified for the default *who* output for systems not supporting the XSI option. In such a user-oriented command, designed only for human use, this was not considered to be a deficiency.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, and *write* require that they use the same format.

It is acceptable for an implementation to produce no output for an invocation of *who* **mil**.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

Issue 7

SD5-XCU-ERN-58 is applied, clarifying the **−b** option.

The *who* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

write ‡'write to another user

SYNOPSIS

```
write user_name [terminal]
```

DESCRIPTION

The *write* utility shall read lines from the standard input and write them to the terminal of the specified user. When first invoked, it shall write the message:

```
Message from sender-login-id (sending-terminal) [date]...
```

to *user_name*. When it has successfully completed the connection, the sender's terminal shall be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.

If the recipient wants to reply, this can be accomplished by typing:

```
write sender-login-id [sending-terminal]
```

upon receipt of the initial message. Whenever a line of input as delimited by an NL, EOF, or EOL special character (see XBD Chapter 11, on page 199) is accumulated while in canonical input mode, the accumulated data shall be written on the other user's terminal. Characters shall be processed as follows:

Typing <alert> shall write the <alert> character to the recipient's terminal.

Typing the erase and kill characters shall affect the sender's terminal in the manner described by the **termios** interface in XBD Chapter 11 (on page 199).

Typing the interrupt or end-of-file characters shall cause *write* to write an appropriate message ("EOT\n" in the POSIX locale) to the recipient's terminal and exit.

Typing characters from *LC_CTYPE* classifications **print** or **space** shall cause those characters to be sent to the recipient's terminal.

When and only when the *stty* **iexten** local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions is implementation-defined.

Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be written to the recipient's terminal.

To write to a user who is logged in more than once, the *terminal* argument can be used to indicate which terminal to write to; otherwise, the recipient's terminal is selected in an implementation-defined manner and an informational message is written to the sender's standard output, indicating which terminal was chosen.

Permission to be a recipient of a *write* message can be denied or granted by use of the *mesg* utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The *write* utility shall fail when the user lacks appropriate privileges to perform the requested action.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

user_name Login name of the person to whom the message shall be written. The application shall ensure that this operand is of the form returned by the *who* utility.

terminal Terminal identification in the same format provided by the *who* utility.

STDIN

Lines to be copied to the recipient's terminal are read from standard input.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *write*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient's locale does not use an *LC_CTYPE* equivalent to the sender's, the results are undefined.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

If an interrupt signal is received, *write* shall write an appropriate message on the recipient's terminal and exit with a status of zero. It shall take the standard action for all other signals.

STDOUT

An informational message shall be written to standard output if a recipient is logged in more than once.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The recipient's terminal is used for output.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 The addressed user is not logged on or the addressed user denies permission.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *talk* utility is considered by some users to be a more usable utility on full-screen terminals.

EXAMPLES

None.

RATIONALE

The *write* utility was included in this volume of POSIX.1-2017 since it can be implemented on all terminal types. The standard developers considered the *talk* utility, which cannot be implemented on certain terminals, to be a ``better'' communications interface. Both of these programs are in widespread use on historical implementations. Therefore, the standard developers decided that both utilities should be specified.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use or accept the same format.

FUTURE DIRECTIONS

None.

Issue 7

The *write* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

xargs — construct argument lists and invoke utility

SYNOPSIS

XSI
```
xargs [−ptx] [−E eofstr] [−I replstr|−L number|−n number]
    [−s size] [utility [argument...]]
```

DESCRIPTION

The *xargs* utility shall construct a command line consisting of the *utility* and *argument* operands specified followed by as many arguments read in sequence from standard input as fit in length and number constraints specified by the options. The *xargs* utility shall then invoke the constructed command line and wait for its completion. This sequence shall be repeated until one of the following occurs:

An end-of-file condition is detected on standard input.

An argument consisting of just the logical end-of-file string (see the **−E** *eofstr* option) is found on standard input after double-quote processing, <apostrophe> processing, and <backslash>-escape processing (see next paragraph). All arguments up to but not including the argument consisting of just the logical end-of-file string shall be used as arguments in constructed command lines.

An invocation of a constructed command line returns an exit status of 255.

The application shall ensure that arguments in the standard input are separated by unquoted <blank> characters, unescaped <blank> characters, or <newline> characters. A string of zero or more non-double-quote (`'"'`) characters and non-<newline> characters can be quoted by enclosing them in double-quotes. A string of zero or more non-<apostrophe> (`'\''`) characters and non-<newline> characters can be quoted by enclosing them in <apostrophe> characters. Any unquoted character can be escaped by preceding it with a <backslash>. The utility named by *utility* shall be executed one or more times until the end-of-file is reached or the logical end-of file string is found. The results are unspecified if the utility named by *utility* attempts to read from its standard input.

The generated command line length shall be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The *xargs* utility shall limit the command line length such that when the command line is invoked, the combined argument and environment lists (see the *exec* family of functions in the System Interfaces volume of POSIX.1-2017) shall not exceed {ARG_MAX}−2 048 bytes. Within this constraint, if neither the **−n** nor the **−s** option is specified, the default command line length shall be at least {LINE_MAX}.

OPTIONS

The *xargs* utility shall conform to XBD Section 12.2 (on page 216).

The following options shall be supported:

−E *eofstr* Use *eofstr* as the logical end-of-file string. If **−E** is not specified, it is unspecified whether the logical end-of-file string is the <underscore> character (`'_'`) or the end-of-file string capability is disabled. When *eofstr* is the null string, the logical end-of-file string capability shall be disabled and <underscore> characters shall be taken literally.

XSI **−I** *replstr* Insert mode: *utility* is executed for each logical line from standard input. Arguments in the standard input shall be separated only by unescaped <newline> characters, not by <blank> characters. Any unquoted unescaped <blank> characters at the beginning of each line shall be ignored. The resulting argument shall be inserted in *arguments* in place of each occurrence of *replstr*. At least five

arguments in *arguments* can each contain one or more instances of *replstr*. Each of these constructed arguments cannot grow larger than an implementation-defined limit greater than or equal to 255 bytes. Option **–x** shall be forced on.

XSI **–L** *number* The *utility* shall be executed for each non-empty *number* lines of arguments from standard input. The last invocation of *utility* shall be with fewer lines of arguments if fewer than *number* remain. A line is considered to end with the first <newline> unless the last character of the line is an unescaped <blank>; a trailing unescaped <blank> signals continuation to the next non-empty line, inclusive.

–n *number* Invoke *utility* using as many standard input arguments as possible, up to *number* (a positive decimal integer) arguments maximum. Fewer arguments shall be used if:

The command line length accumulated exceeds the size specified by the **–s** option (or {LINE_MAX} if there is no **–s** option).

The last iteration has fewer than *number*, but not zero, operands remaining.

–p Prompt mode: the user is asked whether to execute *utility* at each invocation. Trace mode (**–t**) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response read from **/dev/tty** shall execute the command; otherwise, that particular invocation of *utility* shall be skipped.

–s *size* Invoke *utility* using as many standard input arguments as possible yielding a command line length less than *size* (a positive decimal integer) bytes. Fewer arguments shall be used if:

The total number of arguments exceeds that specified by the **–n** option.

XSI The total number of lines exceeds that specified by the **–L** option.

End-of-file is encountered on standard input before *size* bytes are accumulated.

Values of *size* up to at least {LINE_MAX} bytes shall be supported, provided that the constraints specified in the DESCRIPTION are met. It shall not be considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in the DESCRIPTION is given; *xargs* shall use the largest value it supports within the constraints.

–t Enable trace mode. Each generated command line shall be written to standard error just prior to invocation.

–x Terminate if a constructed command line will not fit in the implied or specified size (see the **–s** option above).

OPERANDS

The following operands shall be supported:

utility The name of the utility to be invoked, found by search path using the *PATH* environment variable, described in XBD Chapter 8 (on page 173). If *utility* is omitted, the default shall be the *echo* utility. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2384), the results are undefined.

argument An initial option or operand for the invocation of *utility*.

116451 **STDIN**

116452 The standard input shall be a text file. The results are unspecified if an end-of-file condition is
116453 detected immediately following an escaped <newline>.

116454 **INPUT FILES**

116455 The file **/dev/tty** shall be used to read responses required by the −**p** option.

116456 **ENVIRONMENT VARIABLES**

116457 The following environment variables shall affect the execution of *xargs*:

116458 *LANG* Provide a default value for the internationalization variables that are unset or null.
116459 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
116460 variables used to determine the values of locale categories.)

116461 *LC_ALL* If set to a non-empty string value, override the values of all the other
116462 internationalization variables.

116463 *LC_COLLATE*
116464 Determine the locale for the behavior of ranges, equivalence classes, and multi-
116465 character collating elements used in the extended regular expression defined for
116466 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

116467 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
116468 characters (for example, single-byte as opposed to multi-byte characters in
116469 arguments and input files) and the behavior of character classes used in the
116470 extended regular expression defined for the **yesexpr** locale keyword in the
116471 *LC_MESSAGES* category.

116472 *LC_MESSAGES*
116473 Determine the locale used to process affirmative responses, and the locale used to
116474 affect the format and contents of diagnostic messages and prompts written to
116475 standard error.

116476 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

116477 *PATH* Determine the location of *utility*, as described in XBD Chapter 8 (on page 173).

116478 **ASYNCHRONOUS EVENTS**

116479 Default.

116480 **STDOUT**

116481 Not used.

116482 **STDERR**

116483 The standard error shall be used for diagnostic messages and the −**t** and −**p** options. If the −**t**
116484 option is specified, the *utility* and its constructed argument list shall be written to standard error,
116485 as it will be invoked, prior to invocation. If −**p** is specified, a prompt of the following format
116486 shall be written (in the POSIX locale):

116487 `"?..."`

116488 at the end of the line of the output from −**t**.

116489 **OUTPUT FILES**

116490 None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All invocations of *utility* returned exit status zero.

1-125 A command line meeting the specified requirements could not be assembled, one or more of the invocations of *utility* returned a non-zero exit status, or some other error occurred.

126 The utility specified by *utility* was found but could not be invoked.

127 The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the *xargs* utility shall write a diagnostic message and exit without processing any remaining input.

APPLICATION USAGE

The 255 exit status allows a utility being used by *xargs* to tell *xargs* to terminate if it knows no further invocations using the current data stream will succeed. Thus, *utility* should explicitly *exit* with an appropriate value to avoid accidentally returning with 255.

Note that since input is parsed as lines, <blank> characters separate arguments, and <backslash>, <apostrophe>, and double-quote characters are used for quoting, if *xargs* is used to bundle the output of commands like *find dir* −**print** or *ls* into commands to be executed, unexpected results are likely if any filenames contain <blank>, <newline>, or quoting characters. This can be solved by using find to call a script that converts each file found into a quoted string that is then piped to *xargs*, but in most cases it is preferable just to have *find* do the argument aggregation itself by using −**exec** with a `'+'` terminator instead of `';'`. Note that the quoting rules used by *xargs* are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules. An easy (but inefficient) method that can be used to transform input consisting of one argument per line into a quoted form that *xargs* interprets correctly is to precede each non-<newline> character with a <backslash>. More efficient alternatives are shown in Example 2 and Example 5 below.

On implementations with a large value for {ARG_MAX}, *xargs* may produce command lines longer than {LINE_MAX}. For invocation of utilities, this is not a problem. If *xargs* is being used to create a text file, users should explicitly set the maximum command line length with the −**s** option.

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ``failure to find a utility'' from ``invoked utility exited with an error indication''. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ``normal error conditions'' and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

1. The following command combines the output of the parenthesized commands (minus the <apostrophe> characters) onto one line, which is then appended to the file log. It assumes that the expansion of `"$0 $*"` does not include any <apostrophe> or <newline> characters.

   ```
   (logname; date; printf "'%s'\n" "$0 $*") | xargs -E "" >>log
   ```

2. The following command invokes *diff* with successive pairs of arguments originally typed as command line arguments. It assumes there are no embedded <newline> characters in the elements of the original argument list.

   ```
   printf "%s\n" "$@" | sed 's/[^[:alnum:]]/\\&/g' |
       xargs -E "" -n 2 -x diff
   ```

3. In the following commands, the user is asked which files in the current directory (excluding dotfiles) are to be archived. The files are archived into **arch**; *a*, one at a time or *b*, many at a time. The commands assume that no filenames contain <blank>, <newline>, <backslash>, <apostrophe>, or double-quote characters.

   ```
   a. ls | xargs -E "" -p -L 1 ar -r arch
   ```

   ```
   b. ls | xargs -E "" -p -L 1 | xargs -E "" ar -r arch
   ```

4. The following command invokes *command1* one or more times with multiple arguments, stopping if an invocation of *command1* has a non-zero exit status.

   ```
   xargs -E "" sh -c 'command1 "$@" || exit 255' sh < xargs_input
   ```

5. On XSI-conformant systems, the following command moves all files from directory **$1** to directory **$2**, and echoes each move command just before doing it. It assumes no filenames contain <newline> characters and that neither **$1** nor **$2** contains the sequence `"{}"`.

   ```
   ls -A "$1" | sed -e 's/"/"\\""/g' -e 's/.*/"&"/' |
       xargs -E "" -I {} -t mv "$1"/{} "$2"/{}
   ```

RATIONALE

The *xargs* utility was usually found only in System V-based systems; BSD systems included an *apply* utility that provided functionality similar to *xargs* **−n** *number*. The SVID lists *xargs* as a software development extension. This volume of POSIX.1-2017 does not share the view that it is used only for development, and therefore it is not optional.

The classic application of the *xargs* utility is in conjunction with the *find* utility to reduce the number of processes launched by a simplistic use of the *find* **−exec** combination. The *xargs* utility is also used to enforce an upper limit on memory required to launch a process. With this basis in mind, this volume of POSIX.1-2017 selected only the minimal features required.

Although the 255 exit status is mostly an accident of historical implementations, it allows a utility being used by *xargs* to tell *xargs* to terminate if it knows no further invocations using the current data stream shall succeed. Any non-zero exit status from a utility falls into the 1-125 range when *xargs* exits. There is no statement of how the various non-zero utility exit status codes are accumulated by *xargs*. The value could be the addition of all codes, their highest value, the last one received, or a single value such as 1. Since no algorithm is arguably better than the others, and since many of the standard utilities say little more (portably) than ``pass/fail'', no new algorithm was invented.

Several other *xargs* options were removed because simple alternatives already exist within this

volume of POSIX.1-2017. For example, the **−i** *replstr* option can be just as efficiently performed using a shell **for** loop. Since *xargs* calls an *exec* function with each input line, the **−i** option does not usually exploit the grouping capabilities of *xargs*.

The requirement that *xargs* never produces command lines such that invocation of *utility* is within 2 048 bytes of hitting the POSIX *exec* {ARG_MAX} limitations is intended to guarantee that the invoked utility has room to modify its environment variables and command line arguments and still be able to invoke another utility. Note that the minimum {ARG_MAX} allowed by the System Interfaces volume of POSIX.1-2017 is 4 096 bytes and the minimum value allowed by this volume of POSIX.1-2017 is 2 048 bytes; therefore, the 2 048 bytes difference seems reasonable. Note, however, that *xargs* may never be able to invoke a utility if the environment passed in to *xargs* comes close to using {ARG_MAX} bytes.

The version of *xargs* required by this volume of POSIX.1-2017 is required to wait for the completion of the invoked command before invoking another command. This was done because historical scripts using *xargs* assumed sequential execution. Implementations wanting to provide parallel operation of the invoked utilities are encouraged to add an option enabling parallel invocation, but should still wait for termination of all of the children before *xargs* terminates normally.

The **−e** option was omitted from the ISO POSIX-2: 1993 standard in the belief that the *eofstr* option-argument was recognized only when it was on a line by itself and before quote and escape processing were performed, and that the logical end-of-file processing was only enabled if a **−e** option was specified. In that case, a simple *sed* script could be used to duplicate the **−e** functionality. Further investigation revealed that:

> The logical end-of-file string was checked for after quote and escape processing, making a *sed* script that provided equivalent functionality much more difficult to write.
>
> The default was to perform logical end-of-file processing with an <underscore> as the logical end-of-file string.

To correct this misunderstanding, the **−E** *eofstr* option was adopted from the X/Open Portability Guide. Users should note that the description of the **−E** option matches historical documentation of the **−e** option (which was not adopted because it did not support the Utility Syntax Guidelines), by saying that if *eofstr* is the null string, logical end-of-file processing is disabled. Historical implementations of *xargs* actually did not disable logical end-of-file processing; they treated a null argument found in the input as a logical end-of-file string. (A null *string* argument could be generated using single or double-quotes (`''` or `""`). Since this behavior was not documented historically, it is considered to be a bug.

The **−I**, **−L**, and **−n** options are mutually-exclusive. Some implementations use the last one specified if more than one is given on a command line; other implementations treat combinations of the options in different ways.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

A second FUTURE DIRECTION is added.

Issue 6

The obsolescent −**e**, −**i**, and −**l** options are removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

The −**p** option is added.

In the INPUT FILES section, the file **/dev/tty** is used to read responses required by the −**p** option.

The STDERR section is updated to describe the −**p** option.

The description of the −**E** option is aligned with the ISO POSIX-2: 1993 standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #123 is applied, changing the description of the *xargs* −**I** option.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

SD5-XCU-ERN-68 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-128 is applied, clarifying the DESCRIPTION of the logical end-of-file string.

SD5-XCU-ERN-132 is applied, updating the EXAMPLES section.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0149 [342] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0203 [499] is applied.

NAME

yacc ‡'yet another compiler compiler' (**DEVELOPMENT**)

SYNOPSIS

CD

```
yacc [-dltv] [-b file_prefix] [-p sym_prefix] grammar
```

DESCRIPTION

The *yacc* utility shall read a description of a context-free grammar in *grammar* and write C source code, conforming to the ISO C standard, to a code file, and optionally header information into a header file, in the current directory. The generated source code shall not depend on any undefined, unspecified, or implementation-defined behavior, except in cases where it is copied directly from the supplied grammar, or in cases that are documented by the implementation. The C code shall define a function and related routines and macros for an automaton that executes a parsing algorithm meeting the requirements in Algorithms (on page 3465).

The form and meaning of the grammar are described in the EXTENDED DESCRIPTION section.

The C source code and header file shall be produced in a form suitable as input for the C compiler (see *c99*).

OPTIONS

The *yacc* utility shall conform to XBD Section 12.2 (on page 216), except for Guideline 9.

The following options shall be supported:

−b *file_prefix* Use *file_prefix* instead of **y** as the prefix for all output filenames. The code file **y.tab.c**, the header file **y.tab.h** (created when **−d** is specified), and the description file **y.output** (created when **−v** is specified), shall be changed to *file_prefix***.tab.c**, *file_prefix***.tab.h**, and *file_prefix***.output**, respectively.

−d Write the header file; by default only the code file is written. See the OUTPUT FILES section.

−l Produce a code file that does not contain any **#line** constructs. If this option is not present, it is unspecified whether the code file or header file contains **#line** directives. This should only be used after the grammar and the associated actions are fully debugged.

−p *sym_prefix*
Use *sym_prefix* instead of **yy** as the prefix for all external names produced by *yacc*. The names affected shall include the functions *yyparse*(), *yylex*(), and *yyerror*(), and the variables *yylval*, *yychar*, and *yydebug*. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the **−p** option; however, the **−p** option shall not affect **#define** symbols generated by *yacc*.

−t Modify conditional compilation directives to permit compilation of debugging code in the code file. Runtime debugging statements shall always be contained in the code file, but by default conditional compilation directives prevent their compilation.

−v Write a file containing a description of the parser and a report of conflicts generated by ambiguities in the grammar.

116689 **OPERANDS**

116690 The following operand is required:

116691 *grammar* A pathname of a file containing instructions, hereafter called *grammar*, for which a
116692 parser is to be created. The format for the grammar is described in the EXTENDED
116693 DESCRIPTION section.

116694 **STDIN**

116695 Not used.

116696 **INPUT FILES**

116697 The file *grammar* shall be a text file formatted as specified in the EXTENDED DESCRIPTION
116698 section.

116699 **ENVIRONMENT VARIABLES**

116700 The following environment variables shall affect the execution of *yacc*:

116701 *LANG* Provide a default value for the internationalization variables that are unset or null.
116702 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
116703 variables used to determine the values of locale categories.)

116704 *LC_ALL* If set to a non-empty string value, override the values of all the other
116705 internationalization variables.

116706 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
116707 characters (for example, single-byte as opposed to multi-byte characters in
116708 arguments and input files).

116709 *LC_MESSAGES*

116710 Determine the locale that should be used to affect the format and contents of
116711 diagnostic messages written to standard error.

116712 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

116713 The *LANG* and *LC_** variables affect the execution of the *yacc* utility as stated. The *main*()
116714 function defined in Yacc Library (on page 3465) shall call:

116715 `setlocale(LC_ALL, "")`

116716 and thus the program generated by *yacc* shall also be affected by the contents of these variables
116717 at runtime.

116718 **ASYNCHRONOUS EVENTS**

116719 Default.

116720 **STDOUT**

116721 Not used.

116722 **STDERR**

116723 If shift/reduce or reduce/reduce conflicts are detected in *grammar*, *yacc* shall write a report of
116724 those conflicts to the standard error in an unspecified format.

116725 Standard error shall also be used for diagnostic messages.

116726 **OUTPUT FILES**

116727 The code file, the header file, and the description file shall be text files. All are described in the
116728 following sections.

Code File

This file shall contain the C source code for the *yyparse*() function. It shall contain code for the various semantic actions with macro substitution performed on them as described in the EXTENDED DESCRIPTION section. It also shall contain a copy of the **#define** statements in the header file. If a **%union** declaration is used, the declaration for YYSTYPE shall also be included in this file.

Header File

The header file shall contain **#define** statements that associate the token numbers with the token names. This allows source files other than the code file to access the token codes. If a **%union** declaration is used, the declaration for YYSTYPE and an *extern YYSTYPE yylval* declaration shall also be included in this file.

Description File

The description file shall be a text file containing a description of the state machine corresponding to the parser, using an unspecified format. Limits for internal tables (see Limits, on page 3466) shall also be reported, in an implementation-defined manner. (Some implementations may use dynamic allocation techniques and have no specific limit values to report.)

EXTENDED DESCRIPTION

The *yacc* command accepts a language that is used to define a grammar for a target language to be parsed by the tables and code generated by *yacc*. The language accepted by *yacc* as a grammar for the target language is described below using the *yacc* input language itself.

The input *grammar* includes rules describing the input structure of the target language and code to be invoked when these rules are recognized to provide the associated semantic action. The code to be executed shall appear as bodies of text that are intended to be C-language code. These bodies of text shall not contain C-language trigraphs. The C-language inclusions are presumed to form a correct function when processed by *yacc* into its output files. The code included in this way shall be executed during the recognition of the target language.

Given a grammar, the *yacc* utility generates the files described in the OUTPUT FILES section. The code file can be compiled and linked using *c99*. If the declaration and programs sections of the grammar file did not include definitions of *main*(), *yylex*(), and *yyerror*(), the compiled output requires linking with externally supplied versions of those functions. Default versions of *main*() and *yyerror*() are supplied in the *yacc* library and can be linked in by using the **–l y** operand to *c99*. The *yacc* library interfaces need not support interfaces with other than the default **yy** symbol prefix. The application provides the lexical analyzer function, *yylex*(); the *lex* utility is specifically designed to generate such a routine.

Input Language

The application shall ensure that every specification file consists of three sections in order: *declarations*, *grammar rules*, and *programs*, separated by double <percent-sign> characters (`"%%"`). The declarations and programs sections can be empty. If the latter is empty, the preceding `"%%"` mark separating it from the rules section can be omitted.

The input is free form text following the structure of the grammar defined below.

Lexical Structure of the Grammar

The <blank>, <newline>, and <form-feed> character shall be ignored, except that the application shall ensure that they do not appear in names or multi-character reserved symbols. Comments shall be enclosed in `"/* ... */"`, and can appear wherever a name is valid.

Names are of arbitrary length, made up of letters, periods (`'.'`), underscores (`'_'`), and non-initial digits. Uppercase and lowercase letters are distinct. Conforming applications shall not use names beginning in **yy** or **YY** since the *yacc* parser uses such names. Many of the names appear in the final output of *yacc*, and thus they should be chosen to conform with any additional rules created by the C compiler to be used. In particular they appear in **#define** statements.

A literal shall consist of a single character enclosed in single-quote characters. All of the escape sequences supported for character constants by the ISO C standard shall be supported by *yacc*.

The relationship with the lexical analyzer is discussed in detail below.

The application shall ensure that the NUL character is not used in grammar rules or literals.

Declarations Section

The declarations section is used to define the symbols used to define the target language and their relationship with each other. In particular, much of the additional information required to resolve ambiguities in the context-free grammar for the target language is provided here.

Usually *yacc* assigns the relationship between the symbolic names it generates and their underlying numeric value. The declarations section makes it possible to control the assignment of these values.

It is also possible to keep semantic information associated with the tokens currently on the parse stack in a user-defined C-language **union**, if the members of the union are associated with the various names in the grammar. The declarations section provides for this as well.

The first group of declarators below all take a list of names as arguments. That list can optionally be preceded by the name of a C union member (called a *tag* below) appearing within `'<'` and `'>'`. (As an exception to the typographical conventions of the rest of this volume of POSIX.1-2017, in this case <*tag*> does not represent a metavariable, but the literal angle bracket characters surrounding a symbol.) The use of *tag* specifies that the tokens named on this line shall be of the same C type as the union member referenced by *tag*. This is discussed in more detail below.

For lists used to define tokens, the first appearance of a given token can be followed by a positive integer (as a string of decimal digits). If this is done, the underlying value assigned to it for lexical purposes shall be taken to be that number.

The following declares *name* to be a token:

`%token` **[**<*tag*>**]** *name* **[***number***] [***name* **[***number***]]...**

If *tag* is present, the C type for all tokens on this line shall be declared to be the type referenced by *tag*. If a positive integer, *number*, follows a *name*, that value shall be assigned to the token.

The following declares *name* to be a token, and assigns precedence to it:

`%left` **[**<*tag*>**]** *name* **[***number***] [***name* **[***number***]]...**
`%right` **[**<*tag*>**]** *name* **[***number***] [***name* **[***number***]]...**

One or more lines, each beginning with one of these symbols, can appear in this section. All tokens on the same line have the same precedence level and associativity; the lines are in order

of increasing precedence or binding strength. **%left** denotes that the operators on that line are left associative, and **%right** similarly denotes right associative operators. If *tag* is present, it shall declare a C type for *name*s as described for **%token**.

The following declares *name* to be a token, and indicates that this cannot be used associatively:

```
%nonassoc [<tag>] name [number] [name [number]]...
```

If the parser encounters associative use of this token it reports an error. If *tag* is present, it shall declare a C type for *name*s as described for **%token**.

The following declares that union member *name*s are non-terminals, and thus it is required to have a *tag* field at its beginning:

```
%type <tag> name...
```

Because it deals with non-terminals only, assigning a token number or using a literal is also prohibited. If this construct is present, *yacc* shall perform type checking; if this construct is not present, the parse stack shall hold only the **int** type.

Every name used in *grammar* not defined by a **%token**, **%left**, **%right**, or **%nonassoc** declaration is assumed to represent a non-terminal symbol. The *yacc* utility shall report an error for any non-terminal symbol that does not appear on the left side of at least one grammar rule.

Once the type, precedence, or token number of a name is specified, it shall not be changed. If the first declaration of a token does not assign a token number, *yacc* shall assign a token number. Once this assignment is made, the token number shall not be changed by explicit assignment.

The following declarators do not follow the previous pattern.

The following declares the non-terminal *name* to be the *start symbol*, which represents the largest, most general structure described by the grammar rules:

```
%start name
```

By default, it is the left-hand side of the first grammar rule; this default can be overridden with this declaration.

The following declares the *yacc* value stack to be a union of the various types of values desired.

```
%union { body of union (in C) }
```

The body of the union shall not contain unbalanced curly brace preprocessing tokens.

By default, the values returned by actions (see below) and the lexical analyzer shall be of type **int**. The *yacc* utility keeps track of types, and it shall insert corresponding union member names in order to perform strict type checking of the resulting parser.

Alternatively, given that at least one <*tag*> construct is used, the union can be declared in a header file (which shall be included in the declarations section by using a **#include** construct within **%{** and **%}**), and a **typedef** used to define the symbol YYSTYPE to represent this union. The effect of **%union** is to provide the declaration of YYSTYPE directly from the *yacc* input.

C-language declarations and definitions can appear in the declarations section, enclosed by the following marks:

```
%{ ... %}
```

These statements shall be copied into the code file, and have global scope within it so that they can be used in the rules and program sections. The statements shall not contain `"%}"` outside a comment, string literal, or multi-character constant.

The application shall ensure that the declarations section is terminated by the token **%%**.

Grammar Rules in yacc

The rules section defines the context-free grammar to be accepted by the function *yacc* generates, and associates with those rules C-language actions and additional precedence information. The grammar is described below, and a formal definition follows.

The rules section is comprised of one or more grammar rules. A grammar rule has the form:

```
A : BODY ;
```

The symbol **A** represents a non-terminal name, and **BODY** represents a sequence of zero or more *name*s, *literal*s, and *semantic action*s that can then be followed by optional *precedence rule*s. Only the names and literals participate in the formation of the grammar; the semantic actions and precedence rules are used in other ways. The <colon> and the <semicolon> are *yacc* punctuation. If there are several successive grammar rules with the same left-hand side, the <vertical-line> (`'|'`) can be used to avoid rewriting the left-hand side; in this case the <semicolon> appears only after the last rule. The BODY part can be empty (or empty of names and literals) to indicate that the non-terminal symbol matches the empty string.

The *yacc* utility assigns a unique number to each rule. Rules using the vertical bar notation are distinct rules. The number assigned to the rule appears in the description file.

The elements comprising a BODY are:

name, *literal* These form the rules of the grammar: *name* is either a *token* or a *non-terminal*; *literal* stands for itself (less the lexically required quotation marks).

semantic action

With each grammar rule, the user can associate actions to be performed each time the rule is recognized in the input process. (Note that the word ``action'' can also refer to the actions of the parser—shift, reduce, and so on.)

These actions can return values and can obtain the values returned by previous actions. These values are kept in objects of type YYSTYPE (see **%union**). The result value of the action shall be kept on the parse stack with the left-hand side of the rule, to be accessed by other reductions as part of their right-hand side. By using the <*tag*> information provided in the declarations section, the code generated by *yacc* can be strictly type checked and contain arbitrary information. In addition, the lexical analyzer can provide the same kinds of values for tokens, if desired.

An action is an arbitrary C statement and as such can do input or output, call subprograms, and alter external variables. An action is one or more C statements enclosed in curly braces `'{'` and `'}'`. The statements shall not contain unbalanced curly brace preprocessing tokens.

Certain pseudo-variables can be used in the action. These are macros for access to data structures known internally to *yacc*.

$$ The value of the action can be set by assigning it to $$. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

$*number* This refers to the value returned by the component specified by the token *number* in the right side of a rule, reading from left to right; *number* can be zero or negative. If *number* is zero or negative, it refers

to the data associated with the name on the parser's stack preceding the leftmost symbol of the current rule. (That is, "`$0`" refers to the name immediately preceding the leftmost name in the current rule to be found on the parser's stack and "`$-1`" refers to the symbol to *its* left.) If *number* refers to an element past the current point in the rule, or beyond the bottom of the stack, the result is undefined. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

$<*tag*>*number*
: These correspond exactly to the corresponding symbols without the *tag* inclusion, but allow for strict type checking (and preclude unwanted type conversions). The effect is that the macro is expanded to use *tag* to select an element from the YYSTYPE union (using *dataname.tag*). This is particularly useful if *number* is not positive.

$<*tag*>$
: This imposes on the reference the type of the union member referenced by *tag*. This construction is applicable when a reference to a left context value occurs in the grammar, and provides *yacc* with a means for selecting a type.

Actions can occur anywhere in a rule (not just at the end); an action can access values returned by actions to its left, and in turn the value it returns can be accessed by actions to its right. An action appearing in the middle of a rule shall be equivalent to replacing the action with a new non-terminal symbol and adding an empty rule with that non-terminal symbol on the left-hand side. The semantic action associated with the new rule shall be equivalent to the original action. The use of actions within rules might introduce conflicts that would not otherwise exist.

By default, the value of a rule shall be the value of the first element in it. If the first element does not have a type (particularly in the case of a literal) and type checking is turned on by **%type**, an error message shall result.

precedence
: The keyword **%prec** can be used to change the precedence level associated with a particular grammar rule. Examples of this are in cases where a unary and binary operator have the same symbolic representation, but need to be given different precedences, or where the handling of an ambiguous if-else construction is necessary. The reserved symbol **%prec** can appear immediately after the body of the grammar rule and can be followed by a token name or a literal. It shall cause the precedence of the grammar rule to become that of the following token name or literal. The action for the rule as a whole can follow **%prec**.

If a program section follows, the application shall ensure that the grammar rules are terminated by **%%**.

Programs Section

The *programs* section can include the definition of the lexical analyzer *yylex*(), and any other functions; for example, those used in the actions specified in the grammar rules. It is unspecified whether the programs section precedes or follows the semantic actions in the output file; therefore, if the application contains any macro definitions and declarations intended to apply to the code in the semantic actions, it shall place them within "`%{ ... %}`" in the declarations section.

Input Grammar

The following input to *yacc* yields a parser for the input to *yacc*. This formal syntax takes precedence over the preceding text syntax description.

The lexical structure is defined less precisely; Lexical Structure of the Grammar (on page 3457) defines most terms. The correspondence between the previous terms and the tokens below is as follows.

IDENTIFIER This corresponds to the concept of *name*, given previously. It also includes literals as defined previously.

C_IDENTIFIER This is a name, and additionally it is known to be followed by a <colon>. A literal cannot yield this token.

NUMBER A string of digits (a non-negative decimal integer).

TYPE, **LEFT**, **MARK**, **LCURL**, **RCURL**
These correspond directly to **%type**, **%left**, **%%**, **%{**, and **%}**.

{...} This indicates C-language source code, with the possible inclusion of `'$'` macros as discussed previously.

```

Conflicts

The parser produced for an input grammar may contain states in which conflicts occur. The conflicts occur because the grammar is not LALR(1). An ambiguous grammar always contains at least one LALR(1) conflict. The *yacc* utility shall resolve all conflicts, using either default rules or user-specified precedence rules.

Conflicts are either shift/reduce conflicts or reduce/reduce conflicts. A shift/reduce conflict is where, for a given state and lookahead symbol, both a shift action and a reduce action are possible. A reduce/reduce conflict is where, for a given state and lookahead symbol, reductions by two different rules are possible.

The rules below describe how to specify what actions to take when a conflict occurs. Not all shift/reduce conflicts can be successfully resolved this way because the conflict may be due to something other than ambiguity, so incautious use of these facilities can cause the language accepted by the parser to be much different from that which was intended. The description file shall contain sufficient information to understand the cause of the conflict. Where ambiguity is the reason either the default or explicit rules should be adequate to produce a working parser.

The declared precedences and associativities (see Declarations Section, on page 3457) are used to resolve parsing conflicts as follows:

1. A precedence and associativity is associated with each grammar rule; it is the precedence and associativity of the last token or literal in the body of the rule. If the **%prec** keyword is used, it overrides this default. Some grammar rules might not have both precedence and associativity.
2. If there is a shift/reduce conflict, and both the grammar rule and the input symbol have precedence and associativity associated with them, then the conflict is resolved in favor of the action (shift or reduce) associated with the higher precedence. If the precedences are the same, then the associativity is used; left associative implies reduce, right associative implies shift, and non-associative implies an error in the string being parsed.
3. When there is a shift/reduce conflict that cannot be resolved by rule 2, the shift is done. Conflicts resolved this way are counted in the diagnostic output described in Error Handling.
4. When there is a reduce/reduce conflict, a reduction is done by the grammar rule that occurs earlier in the input sequence. Conflicts resolved this way are counted in the diagnostic output described in Error Handling.

Conflicts resolved by precedence or associativity shall not be counted in the shift/reduce and reduce/reduce conflicts reported by *yacc* on either standard error or in the description file.

Error Handling

The token **error** shall be reserved for error handling. The name **error** can be used in grammar rules. It indicates places where the parser can recover from a syntax error. The default value of **error** shall be 256. Its value can be changed using a **%token** declaration. The lexical analyzer should not return the value of **error**.

The parser shall detect a syntax error when it is in a state where the action associated with the lookahead symbol is **error**. A semantic action can cause the parser to initiate error handling by executing the macro YYERROR. When YYERROR is executed, the semantic action passes control back to the parser. YYERROR cannot be used outside of semantic actions.

When the parser detects a syntax error, it normally calls *yyerror*() with the character string `"syntax error"` as its argument. The call shall not be made if the parser is still recovering

from a previous error when the error is detected. The parser is considered to be recovering from a previous error until the parser has shifted over at least three normal input symbols since the last error was detected or a semantic action has executed the macro *yyerrok*. The parser shall not call *yyerror*( ) when YYERROR is executed.

The macro function YYRECOVERING shall return 1 if a syntax error has been detected and the parser has not yet fully recovered from it. Otherwise, zero shall be returned.

When a syntax error is detected by the parser, the parser shall check if a previous syntax error has been detected. If a previous error was detected, and if no normal input symbols have been shifted since the preceding error was detected, the parser checks if the lookahead symbol is an endmarker (see Interface to the Lexical Analyzer). If it is, the parser shall return with a non-zero value. Otherwise, the lookahead symbol shall be discarded and normal parsing shall resume.

When YYERROR is executed or when the parser detects a syntax error and no previous error has been detected, or at least one normal input symbol has been shifted since the previous error was detected, the parser shall pop back one state at a time until the parse stack is empty or the current state allows a shift over **error**. If the parser empties the parse stack, it shall return with a non-zero value. Otherwise, it shall shift over **error** and then resume normal parsing. If the parser reads a lookahead symbol before the error was detected, that symbol shall still be the lookahead symbol when parsing is resumed.

The macro *yyerrok* in a semantic action shall cause the parser to act as if it has fully recovered from any previous errors. The macro *yyclearin* shall cause the parser to discard the current lookahead token. If the current lookahead token has not yet been read, *yyclearin* shall have no effect.

The macro YYACCEPT shall cause the parser to return with the value zero. The macro YYABORT shall cause the parser to return with a non-zero value.

Interface to the Lexical Analyzer

The *yylex*( ) function is an integer-valued function that returns a *token number* representing the kind of token read. If there is a value associated with the token returned by *yylex*( ) (see the discussion of *tag* above), it shall be assigned to the external variable *yylval*.

If the parser and *yylex*( ) do not agree on these token numbers, reliable communication between them cannot occur. For (single-byte character) literals, the token is simply the numeric value of the character in the current character set. The numbers for other tokens can either be chosen by *yacc*, or chosen by the user. In either case, the **#define** construct of C is used to allow *yylex*( ) to return these numbers symbolically. The **#define** statements are put into the code file, and the header file if that file is requested. The set of characters permitted by *yacc* in an identifier is larger than that permitted by C. Token names found to contain such characters shall not be included in the **#define** declarations.

If the token numbers are chosen by *yacc*, the tokens other than literals shall be assigned numbers greater than 256, although no order is implied. A token can be explicitly assigned a number by following its first appearance in the declarations section with a number. Names and literals not defined this way retain their default definition. All token numbers assigned by *yacc* shall be unique and distinct from the token numbers used for literals and user-assigned tokens. If duplicate token numbers cause conflicts in parser generation, *yacc* shall report an error; otherwise, it is unspecified whether the token assignment is accepted or an error is reported.

The end of the input is marked by a special token called the *endmarker*, which has a token number that is zero or negative. (These values are invalid for any other token.) All lexical analyzers shall return zero or negative as a token number upon reaching the end of their input.

If the tokens up to, but excluding, the endmarker form a structure that matches the start symbol, the parser shall accept the input. If the endmarker is seen in any other context, it shall be considered an error.

Completing the Program

In addition to *yyparse*() and *yylex*(), the functions *yyerror*() and *main*() are required to make a complete program. The application can supply *main*() and *yyerror*(), or those routines can be obtained from the *yacc* library.

Yacc Library

The following functions shall appear only in the *yacc* library accessible through the **–l y** operand to *c99*; they can therefore be redefined by a conforming application:

int *main*(**void**)
: This function shall call *yyparse*() and exit with an unspecified value. Other actions within this function are unspecified.

int *yyerror*(**const char** **s*)
: This function shall write the NUL-terminated argument to standard error, followed by a <newline>.

The order of the **–l y** and **–l l** operands given to *c99* is significant; the application shall either provide its own *main*() function or ensure that **–l y** precedes **–l l**.

Debugging the Parser

The parser generated by *yacc* shall have diagnostic facilities in it that can be optionally enabled at either compile time or at runtime (if enabled at compile time). The compilation of the runtime debugging code is under the control of YYDEBUG, a preprocessor symbol. If YYDEBUG has a non-zero value, the debugging code shall be included. If its value is zero, the code shall not be included.

In parsers where the debugging code has been included, the external **int** *yydebug* can be used to turn debugging on (with a non-zero value) and off (zero value) at runtime. The initial value of *yydebug* shall be zero.

When **–t** is specified, the code file shall be built such that, if YYDEBUG is not already defined at compilation time (using the *c99* **–D** YYDEBUG option, for example), YYDEBUG shall be set explicitly to 1. When **–t** is not specified, the code file shall be built such that, if YYDEBUG is not already defined, it shall be set explicitly to zero.

The format of the debugging output is unspecified but includes at least enough information to determine the shift and reduce actions, and the input symbols. It also provides information about error recovery.

Algorithms

The parser constructed by *yacc* implements an LALR(1) parsing algorithm as documented in the literature. It is unspecified whether the parser is table-driven or direct-coded.

A parser generated by *yacc* shall never request an input symbol from *yylex*() while in a state where the only actions other than the error action are reductions by a single rule.

The literature of parsing theory defines these concepts.

Limits

The *yacc* utility may have several internal tables. The minimum maximums for these tables are shown in the following table. The exact meaning of these values is implementation-defined. The implementation shall define the relationship between these values and between them and any error messages that the implementation may generate should it run out of space for any internal structure. An implementation may combine groups of these resources into a single pool as long as the total available to the user does not fall below the sum of the sizes specified by this section.

Table 4-23 Internal Limits in *yacc*

Limit	Minimum Maximum	Description
{NTERMS}	126	Number of tokens.
{NNONTERM}	200	Number of non-terminals.
{NPROD}	300	Number of rules.
{NSTATES}	600	Number of states.
{MEMSIZE}	5 200	Length of rules. The total length, in names (tokens and non-terminals), of all the rules of the grammar. The left-hand side is counted for each rule, even if it is not explicitly repeated, as specified in Grammar Rules in yacc (on page 3459).
{ACTSIZE}	4 000	Number of actions. ``Actions'' here (and in the description file) refer to parser actions (shift, reduce, and so on) not to semantic actions defined in Grammar Rules in yacc (on page 3459).

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If any errors are encountered, the run is aborted and *yacc* exits with a non-zero status. Partial code files and header files may be produced. The summary information in the description file shall always be produced if the **−v** flag is present.

APPLICATION USAGE

Historical implementations experience name conflicts on the names **yacc.tmp**, **yacc.acts**, **yacc.debug**, **y.tab.c**, **y.tab.h**, and **y.output** if more than one copy of *yacc* is running in a single directory at one time. The **−b** option was added to overcome this problem. The related problem of allowing multiple *yacc* parsers to be placed in the same file was addressed by adding a **−p** option to override the previously hard-coded **yy** variable prefix.

The description of the **−p** option specifies the minimal set of function and variable names that cause conflict when multiple parsers are linked together. YYSTYPE does not need to be changed. Instead, the programmer can use **−b** to give the header files for different parsers different names, and then the file with the *yylex*( ) for a given parser can include the header for that parser. Names such as *yyclearerr* do not need to be changed because they are used only in the actions; they do not have linkage. It is possible that an implementation has other names, either internal ones for implementing things such as *yyclearerr*, or providing non-standard features that it wants

to change with **−p**.

Unary operators that are the same token as a binary operator in general need their precedence adjusted. This is handled by the **%prec** advisory symbol associated with the particular grammar rule defining that unary operator. (See Grammar Rules in yacc (on page 3459).) Applications are not required to use this operator for unary operators, but the grammars that do not require it are rare.

EXAMPLES

Access to the *yacc* library is obtained with library search operands to *c99*. To use the *yacc* library *main*():

```
c99 y.tab.c −l y
```

Both the *lex* library and the *yacc* library contain *main*(). To access the *yacc main*():

```
c99 y.tab.c lex.yy.c −l y −l l
```

This ensures that the *yacc* library is searched first, so that its *main*() is used.

The historical *yacc* libraries have contained two simple functions that are normally coded by the application programmer. These functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
    extern int yyparse();
    setlocale(LC_ALL, "");
    /* If the following parser is one created by lex, the
       application must be careful to ensure that LC_CTYPE
       and LC_COLLATE are set to the POSIX locale. */
    (void) yyparse();
    return (0);
}
#include <stdio.h>
int yyerror(const char *msg)
{
    (void) fprintf(stderr, "%s\n", msg);
    return (0);
}
```

RATIONALE

The references in **Referenced Documents** may be helpful in constructing the parser generator. The referenced DeRemer and Pennello article (along with the works it references) describes a technique to generate parsers that conform to this volume of POSIX.1-2017. Work in this area continues to be done, so implementors should consult current literature before doing any new implementations. The original Knuth article is the theoretical basis for this kind of parser, but the tables it generates are impractically large for reasonable grammars and should not be used. The ``equivalent to'' wording is intentional to assure that the best tables that are LALR(1) can be generated.

There has been confusion between the class of grammars, the algorithms needed to generate parsers, and the algorithms needed to parse the languages. They are all reasonably orthogonal. In particular, a parser generator that accepts the full range of LR(1) grammars need not generate a table any more complex than one that accepts SLR(1) (a relatively weak class of LR grammars)

for a grammar that happens to be SLR(1). Such an implementation need not recognize the case, either; table compression can yield the SLR(1) table (or one even smaller than that) without recognizing that the grammar is SLR(1). The speed of an LR(1) parser for any class is dependent more upon the table representation and compression (or the code generation if a direct parser is generated) than upon the class of grammar that the table generator handles.

The speed of the parser generator is somewhat dependent upon the class of grammar it handles. However, the original Knuth article algorithms for constructing LR parsers were judged by its author to be impractically slow at that time. Although full LR is more complex than LALR(1), as computer speeds and algorithms improve, the difference (in terms of acceptable wall-clock execution time) is becoming less significant.

Potential authors are cautioned that the referenced DeRemer and Pennello article previously cited identifies a bug (an over-simplification of the computation of LALR(1) lookahead sets) in some of the LALR(1) algorithm statements that preceded it to publication. They should take the time to seek out that paper, as well as current relevant work, particularly Aho's.

The **–b** option was added to provide a portable method for permitting *yacc* to work on multiple separate parsers in the same directory. If a directory contains more than one *yacc* grammar, and both grammars are constructed at the same time (by, for example, a parallel *make* program), conflict results. While the solution is not historical practice, it corrects a known deficiency in historical implementations. Corresponding changes were made to all sections that referenced the filenames **y.tab.c** (now ``the code file''), **y.tab.h** (now ``the header file''), and **y.output** (now ``the description file'').

The grammar for *yacc* input is based on System V documentation. The textual description shows there that the `';'` is required at the end of the rule. The grammar and the implementation do not require this. (The use of **C_IDENTIFIER** causes a reduce to occur in the right place.)

Also, in that implementation, the constructs such as **%token** can be terminated by a <semicolon>, but this is not permitted by the grammar. The keywords such as **%token** can also appear in uppercase, which is again not discussed. In most places where `'%'` is used, <backslash> can be substituted, and there are alternate spellings for some of the symbols (for example, **%LEFT** can be `"%<"` or even `"\<"`).

Historically, <*tag*> can contain any characters except `'>'`, including white space, in the implementation. However, since the *tag* must reference an ISO C standard union member, in practice conforming implementations need to support only the set of characters for ISO C standard identifiers in this context.

Some historical implementations are known to accept actions that are terminated by a period. Historical implementations often allow `'$'` in names. A conforming implementation does not need to support either of these behaviors.

Deciding when to use **%prec** illustrates the difficulty in specifying the behavior of *yacc*. There may be situations in which the *grammar* is not, strictly speaking, in error, and yet *yacc* cannot interpret it unambiguously. The resolution of ambiguities in the grammar can in many instances be resolved by providing additional information, such as using **%type** or **%union** declarations. It is often easier and it usually yields a smaller parser to take this alternative when it is appropriate.

The size and execution time of a program produced without the runtime debugging code is usually smaller and slightly faster in historical implementations.

Statistics messages from several historical implementations include the following types of information:

```
n/512 terminals, n/300 non-terminals
n/600 grammar rules, n/1500 states
n shift/reduce, n reduce/reduce conflicts reported
n/350 working sets used
Memory: states, etc. n/15000, parser n/15000
n/600 distinct lookahead sets
n extra closures
n shift entries, n exceptions
n goto entries
n entries saved by goto default
Optimizer space used: input n/15000, output n/15000
n table entries, n zero
Maximum spread: n, Maximum offset: n
```

The report of internal tables in the description file is left implementation-defined because all aspects of these limits are also implementation-defined. Some implementations may use dynamic allocation techniques and have no specific limit values to report.

The format of the **y.output** file is not given because specification of the format was not seen to enhance applications portability. The listing is primarily intended to help human users understand and debug the parser; use of **y.output** by a conforming application script would be unusual. Furthermore, implementations have not produced consistent output and no popular format was apparent. The format selected by the implementation should be human-readable, in addition to the requirement that it be a text file.

Standard error reports are not specifically described because they are seldom of use to conforming applications and there was no reason to restrict implementations.

Some implementations recognize `"={"` as equivalent to `'{'` because it appears in historical documentation. This construction was recognized and documented as obsolete as long ago as 1978, in the referenced *Yacc: Yet Another Compiler-Compiler*. This volume of POSIX.1-2017 chose to leave it as obsolete and omit it.

Multi-byte characters should be recognized by the lexical analyzer and returned as tokens. They should not be returned as multi-byte character literals. The token **error** that is used for error recovery is normally assigned the value 256 in the historical implementation. Thus, the token value 256, which is used in many multi-byte character sets, is not available for use as the value of a user-defined token.

FUTURE DIRECTIONS

None.

c99, *lex*

XBD Chapter 8 (on page 173), Section 12.2 (on page 216)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the C-Language Development Utilities option.

Minor changes have been added to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ``must'' for application requirements.

IEEE PASC Interpretation 1003.2 #177 is applied, changing the comment on **RCURL** from the }% token to the %}.

Issue 7

Austin Group Interpretation 1003.1-2001 #190 is applied, clarifying the requirements for generated code to conform to the ISO C standard.

Austin Group Interpretation 1003.1-2001 #191 is applied, clarifying the handling of C-language trigraphs and curly brace preprocessing tokens.

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0204 [977] is applied.

NAME

zcat ‡'expand and concatenate data

SYNOPSIS

XSI `zcat [file...]`

DESCRIPTION

The *zcat* utility shall write to standard output the uncompressed form of files that have been compressed using the *compress* utility. It is the equivalent of *uncompress* **−c**. Input files are not affected.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file The pathname of a file previously processed by the *compress* utility. If *file* already has the **.Z** suffix specified, it is used as submitted. Otherwise, the **.Z** suffix is appended to the filename prior to processing.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.

INPUT FILES

Input files shall be compressed files that are in the format produced by the *compress* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *zcat*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The compressed files given as input shall be written on standard output in their uncompressed form.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

117423 *Open Group Standard*

117424 **Vol. 4:**

117425 **Rationale (Informative), Issue 7**

117426 *The Open Group*
117427 *The Institute of Electrical and Electronics Engineers, Inc.*

Rationale (Informative)

Part A:

Base Definitions

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Appendix A

Rationale for Base Definitions

A.1 Introduction

A.1.1 Scope

POSIX.1-2017 is one of a family of standards known as POSIX. The family of standards extends to many topics; POSIX.1 consists of both operating system interfaces and shell and utilities. POSIX.1-2017 is technically identical to The Open Group Base Specifications, Issue 7.

Scope of POSIX.1-2017

The (paraphrased) goals of this development were to revise the single document that is ISO/IEC 9945:2003 Parts 1 through 4, IEEE Std 1003.1, 2004 Edition, and the appropriate parts of The Open Group Single UNIX Specification, Version 3. This work has been undertaken by the Austin Group, a joint working group of IEEE, The Open Group, and ISO/IEC JTC 1/SC 22.

The following are the base documents in this version:

IEEE Std 1003.1, 2004 Edition

ISO/IEC 9899:1999, Programming Languages ‡' C, including ISO/IEC 9899:1999/Cor.1:2001(E), ISO/IEC 9899:1999/Cor.2:2004(E), and ISO/IEC 9899:1999/Cor.3

The Open Group Extended API Sets, Parts 1 through 4

This version has addressed the following areas:

Issues raised by Austin Group defect reports, IEEE Interpretations against IEEE Std 1003.1, and ISO/IEC defect reports against ISO/IEC 9945

The repository of interpretations can be accessed at www.opengroup.org/austin/interps.

Issues raised in corrigenda for The Open Group Technical Standards and working group resolutions from The Open Group

Issues arising from ISO TR 24715:2006, Conflicts between POSIX and the LSB

This is a Type 3 informative technical report highlighting differences between the LSB 3.1 and the 2004 Edition of this standard.

Changes to make the text self-consistent with the additional material merged

The new material merged has come from the The Open Group Extended API Sets, Parts 1 through 4. A list of the new interfaces is included in Section B.1.1 (on page 3561).

Features, marked legacy or obsolescent in the base documents, have been considered for removal in this version

See Section B.1.1 (on page 3561) and Section C.1.1 (on page 3707).

A review and reorganization of the options within the standard

This has included marking the following options obsolescent:

‡ Alternate Environment Services and Utilities

‡ Trading

‡ STREAMS

The UUCP Utilities option is a new option for this version.

Functionality from the following former options is now mandatory in this version:

AIO	_POSIX_ASYNCHRONOUS_IO (Asynchronous Input and Output)
BAR	_POSIX_BARRIERS (Barriers)
CS	_POSIX_CLOCK_SELECTION (Clock Selection)
MF	_POSIX_MAPPED_FILES (Memory Mapped Files)
MPR	_POSIX_MEMORY_PROTECTION (Memory Protection)
RTS	_POSIX_REALTIME_SIGNALS (Realtime Signals Extension)
RWL	_POSIX_READER_WRITER_LOCKS (Read-Write Locks)
SEM	_POSIX_SEMAPHORES (Semaphores)
SPI	_POSIX_SPIN_LOCKS (Spin Locks)
THR	_POSIX_THREADS (Threads)
TMO	_POSIX_TIMEOUTS (Timeouts)
TMR	_POSIX_TIMERS (Timers)
TSF	_POSIX_THREAD_SAFE_FUNCTIONS (Thread-Safe Functions)

Alignment with the ISO/IEC 9899:1999 standard, including ISO/IEC 9899:1999/Cor.2:2004(E)

A review of the use of fixed path filenames within the standard

For example, the *at*, *batch*, and *crontab* utilities previously had a requirement for use of the directory **/usr/lib/cron**.

The following were requirements on POSIX.1-2017:

Backward-compatibility

For interfaces carried forward, it was agreed that there should be no breakage of functionality in the existing base documents. All strictly conforming applications will be conforming but not necessarily strictly conforming to the revised standard. The goal is for system implementations to be able to support the existing and revised standards simultaneously.

Architecture and *n*-bit-neutral

The common standard should not make any implicit assumptions about the system architecture or size of data types; for example, previously some 32-bit implicit assumptions had crept into the standards.

Extensibility

It should be possible to extend the common standard without breaking backwards-compatibility; for example, the name space should be reserved and structured to avoid duplication of names between the standard and extensions to it.

117506 **POSIX.1 and the ISO C Standard**

117507 The standard developers believed it essential for a programmer to have a single complete
117508 reference place, but recognized that deference to the formal standard has to be addressed for the
117509 duplicate interface definitions between the ISO C standard and POSIX.1-2017.

117510 Where an interface has a version in the ISO C standard, the DESCRIPTION section describes the
117511 relationship to the ISO C standard and markings are included as appropriate to show where the
117512 ISO C standard has been extended in the text.

117513 A block of text is included at the start of each affected reference page stating whether the page is
117514 aligned with the ISO C standard or extended. Each page has been parsed for additions beyond
117515 the ISO C standard (that is, including both POSIX and UNIX extensions), and these extensions
117516 are marked as CX extensions (for C extensions).

117517 **FIPS Requirements**

117518 The Federal Information Processing Standards (FIPS) are a series of US government
117519 procurement standards managed and maintained on behalf of the US Department of Commerce
117520 by the National Institute of Standards and Technology (NIST).

117521 The following restrictions were integrated into IEEE Std 1003.1-2001. They originally came from
117522 FIPS 151-2 which was withdrawn by NIST on February 25 2000.

117523 The implementation supports _POSIX_CHOWN_RESTRICTED.

117524 The limit {NGROUPS_MAX} is greater than or equal to 8.

117525 The implementation supports the setting of the group ID of a file (when it is created) to
117526 that of the parent directory.

117527 The implementation supports _POSIX_SAVED_IDS.

117528 The implementation supports _POSIX_VDISABLE.

117529 The implementation supports _POSIX_JOB_CONTROL.

117530 The implementation supports _POSIX_NO_TRUNC.

117531 The *read*( ) function returns the number of bytes read when interrupted by a signal and
117532 does not return –1.

117533 The *write*( ) function returns the number of bytes written when interrupted by a signal and
117534 does not return –1.

117535 In the environment for the login shell, the environment variables *LOGNAME* and *HOME*
117536 are defined and have the properties described in POSIX.1-2017.

117537 The value of {CHILD_MAX} is greater than or equal to 25.

117538 The value of {OPEN_MAX} is greater than or equal to 20.

117539 The implementation supports the functionality associated with the symbols CS7, CS8,
117540 CSTOPB, PARODD, and PARENB defined in **<termios.h>**.

A.1.2 Conformance

See Section A.2 (on page 3483).

A.1.3 Normative References

There is no additional rationale provided for this section.

A.1.4 Change History

For Issue 7 onwards, in references to Technical Corrigenda, the original Austin Group defect report numbers that gave rise to the change are included in square brackets after the change number from the Technical Corrigendum. For more information on Austin Group defect reports see www.opengroup.org/austin/defectform.html.

A.1.5 Terminology

The meanings specified in POSIX.1-2017 for the words *shall*, *should*, and *may* are mandated by ISO/IEC directives.

In the Rationale (Informative) volume of POSIX.1-2017, the words *shall*, *should*, and *may* are sometimes used to illustrate similar usages in POSIX.1-2017. However, the rationale itself does not specify anything regarding implementations or applications.

conformance document

As a practical matter, the conformance document is effectively part of the system documentation. Conformance documents are distinguished by POSIX.1-2017 so that they can be referred to distinctly.

implementation-defined

This definition is analogous to that of the ISO C standard and, together with ``undefined'' and ``unspecified'', provides a range of specification of freedom allowed to the interface implementor.

may

The use of *may* has been limited as much as possible, due both to confusion stemming from its ordinary English meaning and to objections regarding the desirability of having as few options as possible and those as clearly specified as possible.

The usage of *can* and *may* were selected to contrast optional application behavior (can) against optional implementation behavior (may).

shall

Declarative sentences are sometimes used in POSIX.1-2017 as if they included the word *shall*, and facilities thus specified are no less required. For example, the two statements:

1. The *foo*( ) function shall return zero.
2. The *foo*( ) function returns zero.

are meant to be exactly equivalent.

should

In POSIX.1-2017, the word *should* does not usually apply to the implementation, but rather to the application. Thus, the important words regarding implementations are *shall*, which indicates requirements, and *may*, which indicates options.

obsolescent

The term ``obsolescent'' means ``do not use this feature in new applications''. A feature noted as obsolescent is supported by all implementations, but may be removed in a future version; new applications should not use these features. The obsolescence concept is not an ideal solution, but was used as a method of increasing consensus: many more objections would be heard from the user community if some of these historical features were suddenly removed without the grace period obsolescence implies. The phrase ``may be removed in a future version'' implies that the result of that consideration might in fact keep those features indefinitely if the predominance of applications do not migrate away from them quickly.

legacy

The term ``legacy'' was included in earlier versions of this standard but is no longer used in the current version.

system documentation

The system documentation should normally describe the whole of the implementation, including any extensions provided by the implementation. Such documents normally contain information at least as detailed as the specifications in POSIX.1-2017. Few requirements are made on the system documentation, but the term is needed to avoid a dangling pointer where the conformance document is permitted to point to the system documentation.

undefined

See *implementation-defined*.

unspecified

See *implementation-defined*.

The definitions for ``unspecified'' and ``undefined'' appear nearly identical at first examination, but are not. The term ``unspecified'' means that a conforming application may deal with the unspecified behavior, and it should not care what the outcome is. The term ``undefined'' says that a conforming application should not do it because no definition is provided for what it does (and implicitly it would care what the outcome was if it tried it). It is important to remember, however, that if the syntax permits the statement at all, it must have some outcome in a real implementation.

Thus, the terms ``undefined'' and ``unspecified'' apply to the way the application should think about the feature. In terms of the implementation, it is always ``defined''—there is always some result, even if it is an error. The implementation is free to choose the behavior it prefers.

This also implies that an implementation, or another standard, could specify or define the result in a useful fashion. The terms apply to POSIX.1-2017 specifically.

The term ``implementation-defined'' implies requirements for documentation that are not required for ``undefined'' (or ``unspecified''). Where there is no need for a conforming program to know the definition, the term ``undefined'' is used, even though ``implementation-defined'' could also have been used in this context. There could be a fourth term, specifying ``this standard does not say what this does; it is acceptable to define it in an implementation, but it does not need to be documented'', and undefined would then be used very rarely for the few things for which any definition is not useful. In particular, implementation-defined is used where it is believed that certain classes of application will need to know such details to determine whether the application can be successfully ported to the implementation. Such applications are not always strictly portable, but nevertheless are common and useful; often the requirements met by the application cannot be met without dealing with the issues implied by ``implementation-defined''. In some places the text refers to facilities supplied by the implementation that are

117629 outside the standard as implementation-supplied or implementation-provided. This is not
117630 intended to imply a requirement for documentation. If it were, the term ``implementation-
117631 defined'' would have been used.

117632 In many places POSIX.1-2017 is silent about the behavior of some possible construct. For
117633 example, a variable may be defined for a specified range of values and behaviors are
117634 described for those values; nothing is said about what happens if the variable has any other
117635 value. That kind of silence can imply an error in the standard, but it may also imply that the
117636 standard was intentionally silent and that any behavior is permitted. There is a natural
117637 tendency to infer that if the standard is silent, a behavior is prohibited. That is not the intent.
117638 Silence is intended to be equivalent to the term ``unspecified''.

117639 Three terms used within POSIX.1-2017 overlap in meaning: ``macro'', ``symbolic name'', and
117640 ``symbolic constant''.

117641 **macro**
117642 This usually describes a C preprocessor symbol, the result of the **#define** operator, with or
117643 without an argument. It may also be used to describe similar mechanisms in editors and
117644 text processors.

117645 **symbolic name**
117646 In earlier versions of this standard this was also sometimes used to refer to a C preprocessor
117647 symbol (without arguments), but the intention is for all such uses to have been removed. It
117648 is now mainly used to refer to the names for characters in character sets, but is sometimes
117649 used to refer to host names and even filenames.

117650 **symbolic constant**
117651 This also refers to a C preprocessor symbol, with specific associated requirements. See the
117652 definition in Section 3.380 (on page 95).

117653 A.1.6 Definitions and Concepts

117654 There is no additional rationale provided for this section.

117655 A.1.7 Portability

117656 To aid the identification of options within POSIX.1-2017, a notation consisting of margin codes
117657 and shading is used. This is based on the notation used in earlier versions of The Open Group
117658 Base specifications.

117659 The benefit of this approach is a reduction in the number of *if* statements within the running
117660 text, that makes the text easier to read, and also an identification to the programmer that they
117661 need to ensure that their target platforms support the underlying options. For example, if
117662 functionality is marked with RPP in the margin, it will be available on all systems supporting
117663 the Robust Mutex Priority Protection option, but may not be available on some others.

117664 *A.1.7.1 Codes*

117665 This section includes codes for options defined in XBD Section 2.1.6 (on page 26), and the
117666 following additional codes for other purposes:

117667 CX This margin code is used to denote extensions beyond the ISO C standard. For
117668 interfaces that are duplicated between POSIX.1-2017 and the ISO C standard, a CX
117669 introduction block describes the nature of the duplication, with any extensions

117670 appropriately CX marked and shaded.

117671 Where an interface is added to an ISO C standard header, within the header the
117672 interface has an appropriate margin marker and shading (for example, CX, XSI, TSF,
117673 and so on) and the same marking appears on the reference page in the SYNOPSIS
117674 section. This enables a programmer to easily identify that the interface is extending an
117675 ISO C standard header.

117676 MX and MXX
117677 These two margin codes both relate to the IEC 60559 Floating-Point option. The MX
117678 code denotes functionality that is mandated by the ISO C standard for IEC 60559
117679 implementations; the MXX code denotes IEC 60559 functionality that is an extension to
117680 the ISO C standard.

117681 OB This margin code is used to denote obsolescent behavior and thus flag a possible future
117682 applications portability warning.

117683 OH The Single UNIX Specification has historically tried to reduce the number of headers an
117684 application has had to include when using a particular interface. Sometimes this was
117685 fewer than the base standard, and hence a notation is used to flag which headers are
117686 optional if you are using a system supporting the XSI option.

117687 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0001 [591] is applied.

117688 *A.1.7.2 Margin Code Notation*

117689 Since some features may depend on one or more options, or require more than one option, a
117690 notation is used. Where a feature requires support of a single option, a single margin code will
117691 occur in the margin. If it depends on two options and both are required, then the codes will
117692 appear with a <space> separator. If either of two options are required, then a logical OR is
117693 denoted using the '|' symbol. If more than two codes are used, a special notation is used.

117694 A.2 Conformance

117695 The terms ``profile'' and ``profiling'' are used throughout this section.

117696 A profile of a standard or standards is a codified set of option selections, such that by being
117697 conformant to a profile, particular classes of users are specifically supported.

117698 A.2.1 Implementation Conformance

117699 These definitions allow application developers to know what to depend on in an
117700 implementation.

117701 There is no definition of a ``strictly conforming implementation''; that would be an
117702 implementation that provides *only* those facilities specified by POSIX.1 with no extensions
117703 whatsoever. This is because no actual operating system implementation can exist without
117704 system administration and initialization facilities that are beyond the scope of POSIX.1.

A.2.1.1 *Requirements*

The word ``support'' is used in certain instances, rather than ``provide'', in order to allow an implementation that has no resident software development facilities, but that supports the execution of a *Strictly Conforming POSIX.1 Application*, to be a *conforming implementation*.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0002 [810] is applied.

A.2.1.2 *Documentation*

The conformance documentation is required to use the same numbering scheme as POSIX.1 for purposes of cross-referencing. All options that an implementation chooses are reflected in **<limits.h>** and **<unistd.h>**.

Note that the use of ``may'' in terms of where conformance documents record where implementations may vary, implies that it is not required to describe those features identified as undefined or unspecified.

Other aspects of systems must be evaluated by purchasers for suitability. Many systems incorporate buffering facilities, maintaining updated data in volatile storage and transferring such updates to non-volatile storage asynchronously. Various exception conditions, such as a power failure or a system crash, can cause this data to be lost. The data may be associated with a file that is still open, with one that has been closed, with a directory, or with any other internal system data structures associated with permanent storage. This data can be lost, in whole or part, so that only careful inspection of file contents could determine that an update did not occur.

Also, interrelated file activities, where multiple files and/or directories are updated, or where space is allocated or released in the file system structures, can leave inconsistencies in the relationship between data in the various files and directories, or in the file system itself. Such inconsistencies can break applications that expect updates to occur in a specific sequence, so that updates in one place correspond with related updates in another place.

For example, if a user creates a file, places information in the file, and then records this action in another file, a system or power failure at this point followed by restart may result in a state in which the record of the action is permanently recorded, but the file created (or some of its information) has been lost. The consequences of this to the user may be undesirable. For a user on such a system, the only safe action may be to require the system administrator to have a policy that requires, after any system or power failure, that the entire file system must be restored from the most recent backup copy (causing all intervening work to be lost).

The characteristics of each implementation will vary in this respect and may or may not meet the requirements of a given application or user. Enforcement of such requirements is beyond the scope of POSIX.1. It is up to the purchaser to determine what facilities are provided in an implementation that affect the exposure to possible data or sequence loss, and also what underlying implementation techniques and/or facilities are provided that reduce or limit such loss or its consequences.

A.2.1.3 *POSIX Conformance*

This really means conformance to the base standard; however, since this document includes the core material of the Single UNIX Specification, the standard developers decided that it was appropriate to segment the conformance requirements into two, the former for the base standard, and the latter for the Single UNIX Specification (denoted XSI Conformance).

Within POSIX.1 there are some symbolic constants that, if defined to a certain value or range of values, indicate that a certain option is enabled. Other symbolic constants exist in POSIX.1 for

other reasons.

In this version, some features that were previously optional have been made mandatory. For backwards compatibility, the symbolic constants associated with the option are still required now with fixed allowable ranges or values. The following options from the previous version of this standard are now mandatory:

_POSIX_ASYNCHRONOUS_IO
_POSIX_BARRIERS
_POSIX_CLOCK_SELECTION
_POSIX_MAPPED_FILES
_POSIX_MEMORY_PROTECTION
_POSIX_READER_WRITER_LOCKS
_POSIX_REALTIME_SIGNALS
_POSIX_SEMAPHORES
_POSIX_SPIN_LOCKS
_POSIX_THREAD_SAFE_FUNCTIONS
_POSIX_THREADS
_POSIX_TIMEOUTS
_POSIX_TIMERS

A POSIX-conformant system may support the XSI option required by the Single UNIX Specification. This was intentional since the standard developers intend them to be upwards-compatible, so that a system conforming to the Single UNIX Specification can also conform to the base standard at the same time.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0003 [637] is applied.

A.2.1.4 XSI Conformance

This section is included to describe the conformance requirements for the base volumes of the Single UNIX Specification.

XSI conformance can be thought of as a profile, selecting certain options from POSIX.1-2017.

A.2.1.5 Option Groups

The concept of ``Option Groups'' is included to allow collections of related functions or options to be grouped together. This has been used as follows: the ``XSI Option Groups'' have been created to allow super-options, collections of underlying options and related functions, to be collectively supported by XSI-conforming systems.

The standard developers considered the matter of subprofiling and decided it was better to include an enabling mechanism rather than detailed normative requirements. A set of subprofiling options was developed and included later in this volume of POSIX.1-2017 as an informative illustration.

Subprofiling Considerations

The goal of not simultaneously fixing maximums and minimums was to allow implementations of the base standard or standards to support multiple profiles without conflict.

The following summarizes the rules for the limit types:

Limit Type	Fixed Value	Minimum Acceptable Value	Maximum Acceptable Value
Standard Profile	*Xs* *Xp* = = *Xs* (No change)	*Ys* *Yp* >= *Ys* (May increase the limit)	*Zs* *Zp* <= *Zs* (May decrease the limit)

The intent is that ranges specified by limits in profiles be entirely contained within the corresponding ranges of the base standard or standards being profiled, and that the unlimited end of a range in a base standard must remain unlimited in any profile of that standard.

Thus, the fixed _POSIX_* limits are constants and must not be changed by a profile. The variable counterparts (typically without the leading _POSIX_) can be changed but still remain semantically the same; that is, they still allow implementation values to vary as long as they meet the requirements for that value (be it a minimum or maximum).

Where a profile does not provide a feature upon which a limit is based, the limit is not relevant. Applications written to that profile should be written to operate independently of the value of the limit.

An example which has previously allowed implementations to support both the base standard and two other profiles in a compatible manner follows:

```
Base standard (POSIX.1-1996): _POSIX_CHILD_MAX 6
Base standard: CHILD_MAX   minimum maximum _POSIX_CHILD_MAX
    FIPS profile/SUSv2  CHILD_MAX   25 (minimum maximum)
```

Another example:

```
Base standard (POSIX.1-1996): _POSIX_NGROUPS_MAX 0
Base standard: NGROUPS_MAX   minimum maximum _POSIX_NGROUP_MAX
    FIPS profile/SUSv2  NGROUPS_MAX   8
```

A profile may lower a minimum maximum below the equivalent _POSIX value:

```
Base standard: _POSIX_foo_MAX   Z
Base standard: foo_MAX   _POSIX_foo_MAX
    profile standard : foo_MAX   X  (X can be less than, equal to,
                                     or greater than  _POSIX_foo_MAX)
```

In this case an implementation conforming to the profile may not conform to the base standard, but an implementation to the base standard will conform to the profile.

A.2.1.6 Options

The final subsections within *Implementation Conformance* list the core options within POSIX.1-2017. This includes both options for the System Interfaces volume of POSIX.1-2017 and the Shell and Utilities volume of POSIX.1-2017.

A.2.2 Application Conformance

These definitions guide users or adapters of applications in determining on which implementations an application will run and how much adaptation would be required to make it run on others. These definitions are modeled after related ones in the ISO C standard.

POSIX.1 occasionally uses the expressions ``portable application'' or ``conforming application''. As they are used, these are synonyms for any of these terms. The differences between the classes of application conformance relate to the requirements for other standards, the options supported (such as the XSI option) or, in the case of the Conforming POSIX.1 Application Using Extensions, to implementation extensions. When one of the less explicit expressions is used, it should be apparent from the context of the discussion which of the more explicit names is appropriate

A.2.2.1 Strictly Conforming POSIX Application

This definition is analogous to that of an ISO C standard ``conforming program''.

The major difference between a Strictly Conforming POSIX Application and an ISO C standard strictly conforming program is that the latter is not allowed to use features of POSIX that are not in the ISO C standard.

A.2.2.2 Conforming POSIX Application

Examples of <National Bodies> include ANSI, BSI, and AFNOR.

A.2.2.3 Conforming POSIX Application Using Extensions

Due to possible requirements for configuration or implementation characteristics in excess of the specifications in **<limits.h>** or related to the hardware (such as array size or file space), not every Conforming POSIX Application Using Extensions will run on every conforming implementation.

A.2.2.4 Strictly Conforming XSI Application

This is intended to be upwards-compatible with the definition of a Strictly Conforming POSIX Application, with the addition of the facilities and functionality included in the XSI option.

A.2.2.5 Conforming XSI Application Using Extensions

Such applications may use extensions beyond the facilities defined by POSIX.1-2017 including the XSI option, but need to document the additional requirements.

A.2.3 Language-Dependent Services for the C Programming Language

POSIX.1 is, for historical reasons, both a specification of an operating system interface, shell and utilities, and a C binding for that specification. Efforts had been previously undertaken to generate a language-independent specification; however, that had failed, and the fact that the ISO C standard is the *de facto* primary language on POSIX and the UNIX system makes this a necessary and workable situation.

A.2.4 Other Language-Related Specifications

There is no additional rationale provided for this section.

A.3 Definitions

The definitions in this section are stated so that they can be used as exact substitutes for the terms in text. They should not contain requirements or cross-references to sections within POSIX.1-2017; that is accomplished by using an informative note. In addition, the term should not be included in its own definition. Where requirements or descriptions need to be addressed but cannot be included in the definitions, due to not meeting the above criteria, these occur in the General Concepts chapter.

In this version, the definitions have been reworked extensively to meet style requirements and to include terms from the base documents (see the Scope).

Many of these definitions are necessarily circular, and some of the terms (such as ``process'') are variants of basic computing science terms that are inherently hard to define. Where some definitions are more conceptual and contain requirements, these appear in the General Concepts chapter. Those listed in this section appear in an alphabetical glossary format of terms.

Some definitions must allow extension to cover terms or facilities that are not explicitly mentioned in POSIX.1-2017. For example, the definition of ``Extended Security Controls'' permits implementations beyond those defined in POSIX.1-2017.

Some terms in the following list of notes do not appear in POSIX.1-2017; these are marked suffixed with an asterisk (*). Many of them have been specifically excluded from POSIX.1-2017 because they concern system administration, implementation, or other issues that are not specific to the programming interface. Those are marked with a reason, such as ``implementation-defined''.

Application

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0004 [937] is applied.

Appropriate Privileges

One of the fundamental security problems with many historical UNIX systems has been that the privilege mechanism is monolithic—a user has either no privileges or *all* privileges. Thus, a successful ``trojan horse'' attack on a privileged process defeats all security provisions. Therefore, POSIX.1 allows more granular privilege mechanisms to be defined. For many historical implementations of the UNIX system, the presence of the term ``appropriate privileges'' in POSIX.1 may be understood as a synonym for ``superuser'' (UID 0). However, other systems have emerged where this is not the case and each discrete controllable action has *appropriate privileges* associated with it. Because this mechanism is implementation-defined, it must be described in the conformance document. Although that description affects several parts of POSIX.1 where the term ``appropriate privilege'' is used, because the term ``implementation-defined'' only appears here, the description of the entire mechanism and its effects on these other sections belongs in this equivalent section of the conformance document. This is especially convenient for implementations with a single mechanism that applies in all areas, since it only needs to be described once.

Async-Signal-Safe Function

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0005 [516] is applied.

Base Character*

The term ``Base Character'' has been removed, as it was felt that the use of this term within POSIX.1-2017 was common usage English.

Basename

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0006 [653] is applied.

Byte

The restriction that a byte is now exactly eight bits was a conscious decision by the standard developers. It came about due to a combination of factors, primarily the use of the type **int8_t** within the networking functions and the alignment with the ISO/IEC 9899:1999 standard, where the **intN_t** types are now defined.

According to the ISO/IEC 9899:1999 standard:

> The **[u]intN_t** types must be two's complement with no padding bits and no illegal values.
>
> All types (apart from bit fields, which are not relevant here) must occupy an integral number of bytes.
>
> If a type with width W occupies B bytes with C bits per byte (C is the value of {CHAR_BIT}), then it has P padding bits where $P+W=B*C$.
>
> Therefore, for **int8_t** $P=0$, $W=8$. Since $B \geq 1$, $C \geq 8$, the only solution is $B=1$, $C=8$.

The standard developers also felt that this was not an undue restriction for the current state-of-the-art for this version of the standard, but recognize that if industry trends continue, a wider character type may be required in the future.

Character

The term ``character'' is used to mean a sequence of one or more bytes representing a single graphic symbol. The deviation in the exact text of the ISO C standard definition for ``byte'' meets the intent of the rationale of the ISO C standard also clears up the ambiguity raised by the term ``basic execution character set''. The octet-minimum requirement is a reflection of the {CHAR_BIT} value.

Child Process

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/3 is applied, adding the *vfork*() function to those listed.

Clock Tick

The ISO C standard defines a similar interval for use by the *clock*() function. There is no requirement that these intervals be the same. In historical implementations these intervals are different.

Command

The terms ``command'' and ``utility'' are related but have distinct meanings. Command is defined as ``a directive to a shell to perform a specific task''. The directive can be in the form of a single utility name (for example, *ls*), or the directive can take the form of a compound command (for example, "`ls | grep name | pr`"). A utility is a program that can be called by name from a shell. Issuing only the name of the utility to a shell is the equivalent of a one-word command. A utility may be invoked as a separate program that executes in a different process than the command language interpreter, or it may be implemented as a part of the command language interpreter. For example, the *echo* command (the directive to perform a specific task) may be implemented such that the *echo* utility (the logic that performs the task of echoing) is in a separate program; therefore, it is executed in a process that is different from the command language interpreter. Conversely, the logic that performs the *echo* utility could be built into the command language interpreter; therefore, it could execute in the same process as the command language interpreter.

The terms ``tool'' and ``application'' can be thought of as being synonymous with ``utility'' from the perspective of the operating system kernel. Tools, applications, and utilities historically have run, typically, in processes above the kernel level. Tools and utilities historically have been a part of the operating system non-kernel code and have performed system-related functions, such as listing directory contents, checking file systems, repairing file systems, or extracting system status information. Applications have not generally been a part of the operating system, and they perform non-system-related functions, such as word processing, architectural design, mechanical design, workstation publishing, or financial analysis. Utilities have most frequently been provided by the operating system distributor, applications by third-party software distributors, or by the users themselves. Nevertheless, POSIX.1-2017 does not differentiate between tools, utilities, and applications when it comes to receiving services from the system, a shell, or the standard utilities. (For example, the *xargs* utility invokes another utility; it would be of fairly limited usefulness if the users could not run their own applications in place of the standard utilities.) Utilities are not applications in the sense that they are not themselves subject to the restrictions of POSIX.1-2017 or any other standard ‡there is no requirement for *grep*, *stty*, or any of the utilities defined here to be any of the classes of conforming applications.

Column Positions

In most 1-byte character sets, such as ASCII, the concept of column positions is identical to character positions and to bytes. Therefore, it has been historically acceptable for some implementations to describe line folding or tab stops or table column alignment in terms of bytes or character positions. Other character sets pose complications, as they can have internal representations longer than one octet and they can have display characters that have different widths on the terminal screen or printer.

In POSIX.1-2017 the term ``column positions'' has been defined to mean character ‡not byte ‡' positions in input files (such as ``column position 7 of the FORTRAN input''). Output files describe the column position in terms of the display width of the narrowest printable character in the character set, adjusted to fit the characteristics of the output device. It is very possible that *n* column positions will not be able to hold *n* characters in some character sets, unless all of those characters are of the narrowest width. It is assumed that the implementation is aware of the width of the various characters, deriving this information from the value of *LC_CTYPE*, and thus can determine how many column positions to allot for each character in those utilities where it is important.

The term ``column position'' was used instead of the more natural ``column'' because the latter is frequently used in the different contexts of columns of figures, columns of table values, and so on. Wherever confusion might result, these latter types of columns are referred to as ``text

117983 columns''.

117984 **Controlling Terminal**

117985 The question of which of possibly several special files referring to the terminal is meant is not
117986 addressed in POSIX.1. The pathname **/dev/tty** is a synonym for the controlling terminal
117987 associated with a process.

117988 **Device Number***

117989 The concept is handled in *stat*( ) as *ID of device*.

117990 **Direct I/O**

117991 Historically, direct I/O refers to the system bypassing intermediate buffering, but may be
117992 extended to cover implementation-defined optimizations.

117993 **Directory**

117994 The format of the directory file is implementation-defined and differs radically between
117995 System V and 4.3 BSD. However, routines (derived from 4.3 BSD) for accessing directories and
117996 certain constraints on the format of the information returned by those routines are described in
117997 the **<dirent.h>** header.

117998 **Directory Entry**

117999 Throughout POSIX.1-2017, the term ``link'' is used (about the *link*( ) function, for example) in
118000 describing the objects that point to files from directories.

118001 **Display**

118002 The Shell and Utilities volume of POSIX.1-2017 assigns precise requirements for the terms
118003 ``display'' and ``write''. Some historical systems have chosen to implement certain utilities
118004 without using the traditional file descriptor model. For example, the *vi* editor might employ
118005 direct screen memory updates on a personal computer, rather than a *write*( ) system call. An
118006 instance of user prompting might appear in a dialog box, rather than with standard error. When
118007 the Shell and Utilities volume of POSIX.1-2017 uses the term ``display'', the method of
118008 outputting to the terminal is unspecified; many historical implementations use *termcap* or
118009 *terminfo*, but this is not a requirement. The term ``write'' is used when the Shell and Utilities
118010 volume of POSIX.1-2017 mandates that a file descriptor be used and that the output can be
118011 redirected. However, it is assumed that when the writing is directly to the terminal (it has not
118012 been redirected elsewhere), there is no practical way for a user or test suite to determine whether
118013 a file descriptor is being used. Therefore, the use of a file descriptor is mandated only for the
118014 redirection case and the implementation is free to use any method when the output is not
118015 redirected. The verb *write* is used almost exclusively, with the very few exceptions of those
118016 utilities where output redirection need not be supported: *tabs*, *talk*, *tput*, and *vi*.

118017 **Dot**

118018 The symbolic name *dot* is carefully used in POSIX.1 to distinguish the working directory
118019 filename from a period or a decimal point.

118020 **Dot-Dot**

118021 Historical implementations permit the use of these filenames without their special meanings.
118022 Such use precludes any meaningful use of these filenames by a Conforming POSIX.1
118023 Application. Therefore, such use is considered an extension, the use of which makes an
118024 implementation non-conforming; see also Section A.4.13 (on page 3516).

118025 **Epoch**

118026 Historically, the origin of UNIX system time was referred to as ``00:00:00 GMT, January 1, 1970''.
118027 Greenwich Mean Time is actually not a term acknowledged by the international standards
118028 community; therefore, this term, ``Epoch'', is used to abbreviate the reference to the actual
118029 standard, Coordinated Universal Time.

118030 **FIFO Special File**

118031 See Pipe (on page 3500).

118032 **File**

118033 It is permissible for an implementation-defined file type to be non-readable or non-writable.

118034 **File Classes**

118035 These classes correspond to the historical sets of permission bits. The classes are general to
118036 allow implementations flexibility in expanding the access mechanism for more stringent security
118037 environments. Note that a process is in one and only one class, so there is no ambiguity.

118038 **File Mode**

118039 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0007 [834] is applied.

118040 **Filename**

118041 Filenames are sequences of bytes, not sequences of characters. The only bytes that this standard
118042 says cannot appear in any filename are the slash byte and the null byte. This is a side-effect of
118043 the fact that no conforming implementations of the standard currently provide a way to pass
118044 information specifying the locale associated with strings passed between user-level applications
118045 and the kernel. This decision could be revisited if implementations develop a way to associate a
118046 locale with the strings passed between kernel space and user space.

118047 Implementations may add other restrictions to the byte sequences allowed in filenames except
118048 that any filename consisting of no more than {NAME_MAX} bytes from the set of characters in
118049 the portable filename character set must be allowed.

118050 See Pathname (on page 3500).

118051 **File System**

118052 Historically, the meaning of this term has been overloaded with two meanings: that of the
118053 complete file hierarchy, and that of a mountable subset of that hierarchy; that is, a mounted file
118054 system. POSIX.1 uses the term ``file system'' in the second sense, except that it is limited to the
118055 scope of a process (and root directory of a process). This usage also clarifies the domain in which
118056 a file serial number is unique.

118057 **Graphic Character**

118058 This definition is made available for those definitions (in particular, *TZ*) which must exclude
118059 control characters.

118060 **Group Database**

118061 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/4 is applied, removing the words ``of
118062 implementation-defined format''. See User Database (on page 3510).

118063 **Group File***

118064 Implementation-defined; see User Database (on page 3510).

118065 **Group ID**

118066 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0008 [511] is applied.

118067 **Group Name**

118068 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0009 [584] is applied.

118069 **Historical Implementations***

118070 This refers to previously existing implementations of programming interfaces and operating
118071 systems that are related to the interface specified by POSIX.1.

118072 **Hosted Implementation***

118073 This refers to a POSIX.1 implementation that is accomplished through interfaces from the
118074 POSIX.1 services to some alternate form of operating system kernel services. Note that the line
118075 between a hosted implementation and a native implementation is blurred, since most
118076 implementations will provide some services directly from the kernel and others through some
118077 indirect path. (For example, *fopen*( ) might use *open*( ); or *mkfifo*( ) might use *mknod*( ).) There is
118078 no necessary relationship between the type of implementation and its correctness, performance,
118079 and/or reliability.

118080 **Implementation***

118081 This term is generally used instead of its synonym, ``system'', to emphasize the consequences of
118082 decisions to be made by system implementors. Perhaps if no options or extensions to POSIX.1
118083 were allowed, this usage would not have occurred.

118084 The term ``specific implementation'' is sometimes used as a synonym for ``implementation''.
118085 This should not be interpreted too narrowly; both terms can represent a relatively broad group
118086 of systems. For example, a hardware vendor could market a very wide selection of systems that
118087 all used the same instruction set, with some systems desktop models and others large multi-user
118088 minicomputers. This wide range would probably share a common POSIX.1 operating system,
118089 allowing an application compiled for one to be used on any of the others; this is a [*specific*]
118090 *implementation*. However, such a wide range of machines probably has some differences
118091 between the models. Some may have different clock rates, different file systems, different
118092 resource limits, different network connections, and so on, depending on their sizes or intended
118093 usages. Even on two identical machines, the system administrators may configure them
118094 differently. Each of these different systems is known by the term ``a specific instance of a specific
118095 implementation''. This term is only used in the portions of POSIX.1 dealing with runtime
118096 queries: *sysconf*( ) and *pathconf*( ).

Incomplete Pathname*

Absolute pathname has been adequately defined.

Job Control

In order to understand the job control facilities in POSIX.1 it is useful to understand how they are used by a job control-cognizant shell to create the user interface effect of job control.

While the job control facilities supplied by POSIX.1 can, in theory, support different types of interactive job control interfaces supplied by different types of shells, there was historically one particular interface that was most common when the standard was originally developed (provided by BSD C Shell).

This discussion describes that interface as a means of illustrating how the POSIX.1 job control facilities can be used.

Job control allows users to selectively stop (suspend) the execution of processes and continue (resume) their execution at a later point. The user typically employs this facility via the interactive interface jointly supplied by the terminal I/O driver and a command interpreter (shell).

The user can launch jobs (command pipelines) in either the foreground or background. When launched in the foreground, the shell waits for the job to complete before prompting for additional commands. When launched in the background, the shell does not wait, but immediately prompts for new commands.

If the user launches a job in the foreground and subsequently regrets this, the user can type the suspend character (typically set to <control>-Z), which causes the foreground job to stop and the shell to begin prompting for new commands. The stopped job can be continued by the user (via special shell commands) either as a foreground job or as a background job. Background jobs can also be moved into the foreground via shell commands.

If a background job attempts to access the login terminal (controlling terminal), it is stopped by the terminal driver and the shell is notified, which, in turn, notifies the user. (Terminal access includes *read*() and certain terminal control functions, and conditionally includes *write*().) The user can continue the stopped job in the foreground, thus allowing the terminal access to succeed in an orderly fashion. After the terminal access succeeds, the user can optionally move the job into the background via the suspend character and shell commands.

Implementing Job Control Shells

The interactive interface described previously can be accomplished using the POSIX.1 job control facilities in the following way.

The key feature necessary to provide job control is a way to group processes into jobs. This grouping is necessary in order to direct signals to a single job and also to identify which job is in the foreground. (There is at most one job that is in the foreground on any controlling terminal at a time.)

The concept of process groups is used to provide this grouping. The shell places each job in a separate process group via the *setpgid*() function. To do this, the *setpgid*() function is invoked by the shell for each process in the job. It is actually useful to invoke *setpgid*() twice for each process: once in the child process, after calling *fork*() to create the process, but before calling one of the *exec* family of functions to begin execution of the program, and once in the parent shell process, after calling *fork*() to create the child. The redundant invocation avoids a race condition by ensuring that the child process is placed into the new process group before either the parent or the child relies on this being the case. The process group ID for the job is selected by the shell to be equal to the process ID of one of the processes in the job. Some shells choose to make one

process in the job be the parent of the other processes in the job (if any). Other shells (for example, the C Shell) choose to make themselves the parent of all processes in the pipeline (job). In order to support this latter case, the *setpgid*( ) function accepts a process group ID parameter since the correct process group ID cannot be inherited from the shell. The shell itself is considered to be a job and is the sole process in its own process group.

The shell also controls which job is currently in the foreground. A foreground and background job differ in two ways: the shell waits for a foreground command to complete (or stop) before continuing to read new commands, and the terminal I/O driver inhibits terminal access by background jobs (causing the processes to stop). Thus, the shell must work cooperatively with the terminal I/O driver and have a common understanding of which job is currently in the foreground. It is the user who decides which command should be currently in the foreground, and the user informs the shell via shell commands. The shell, in turn, informs the terminal I/O driver via the *tcsetpgrp*( ) function. This indicates to the terminal I/O driver the process group ID of the foreground process group (job). When the current foreground job either stops or terminates, the shell places itself in the foreground via *tcsetpgrp*( ) before prompting for additional commands. Note that when a job is created the new process group begins as a background process group. It requires an explicit act of the shell via *tcsetpgrp*( ) to move a process group (job) into the foreground.

When a process in a job stops or terminates, its parent (for example, the shell) receives synchronous notification by calling the *waitpid*( ) function with the WUNTRACED flag set. Asynchronous notification is also provided when the parent establishes a signal handler for SIGCHLD and does not specify the SA_NOCLDSTOP flag. Usually all processes in a job stop as a unit since the terminal I/O driver always sends job control stop signals to all processes in the process group.

To continue a stopped job, the shell sends the SIGCONT signal to the process group of the job. In addition, if the job is being continued in the foreground, the shell invokes *tcsetpgrp*( ) to place the job in the foreground before sending SIGCONT. Otherwise, the shell leaves itself in the foreground and reads additional commands.

There is additional flexibility in the POSIX.1 job control facilities that allows deviations from the typical interface. Clearing the TOSTOP terminal flag allows background jobs to perform *write*( ) functions without stopping. The same effect can be achieved on a per-process basis by having a process set the signal action for SIGTTOU to SIG_IGN.

Note that the terms ``job'' and ``process group'' can be used interchangeably. A login session that is not using the job control facilities can be thought of as a large collection of processes that are all in the same job (process group). Such a login session may have a partial distinction between foreground and background processes; that is, the shell may choose to wait for some processes before continuing to read new commands and may not wait for other processes. However, the terminal I/O driver will consider all these processes to be in the foreground since they are all members of the same process group.

In addition to the basic job control operations already mentioned, a job control-cognizant shell needs to perform the following actions.

When a foreground (not background) job stops, the shell must sample and remember the current terminal settings so that it can restore them later when it continues the stopped job in the foreground (via the *tcgetattr*( ) and *tcsetattr*( ) functions).

Because a shell itself can be spawned from a shell, it must take special action to ensure that subshells interact well with their parent shells.

A subshell can be spawned to perform an interactive function (prompting the terminal for commands) or a non-interactive function (reading commands from a file). When operating non-

118191 interactively, the job control shell will refrain from performing the job control-specific actions
118192 described above. It will behave as a shell that does not support job control. For example, all jobs
118193 will be left in the same process group as the shell, which itself remains in the process group
118194 established for it by its parent. This allows the shell and its children to be treated as a single job
118195 by a parent shell, and they can be affected as a unit by terminal keyboard signals.

118196 An interactive subshell can be spawned from another job control-cognizant shell in either the
118197 foreground or background. (For example, from the C Shell, the user can execute the command,
118198 csh *&*.) Before the subshell activates job control by calling *setpgid*() to place itself in its own
118199 process group and *tcsetpgrp*() to place its new process group in the foreground, it needs to
118200 ensure that it has already been placed in the foreground by its parent. (Otherwise, there could
118201 be multiple job control shells that simultaneously attempt to control mediation of the terminal.)
118202 To determine this, the shell retrieves its own process group via *getpgrp*() and the process group
118203 of the current foreground job via *tcgetpgrp*(). If these are not equal, the shell sends SIGTTIN to
118204 its own process group, causing itself to stop. When continued later by its parent, the shell
118205 repeats the process group check. When the process groups finally match, the shell is in the
118206 foreground and it can proceed to take control. After this point, the shell ignores all the job
118207 control stop signals so that it does not inadvertently stop itself.

118208 *Implementing Job Control Applications*

118209 Most applications do not need to be aware of job control signals and operations; the intuitively
118210 correct behavior happens by default. However, sometimes an application can inadvertently
118211 interfere with normal job control processing, or an application may choose to overtly effect job
118212 control in cooperation with normal shell procedures.

118213 An application can inadvertently subvert job control processing by ``blindly'' altering the
118214 handling of signals. A common application error is to learn how many signals the system
118215 supports and to ignore or catch them all. Such an application makes the assumption that it does
118216 not know what this signal is, but knows the right handling action for it. The system may
118217 initialize the handling of job control stop signals so that they are being ignored. This allows
118218 shells that do not support job control to inherit and propagate these settings and hence to be
118219 immune to stop signals. A job control shell will set the handling to the default action and
118220 propagate this, allowing processes to stop. In doing so, the job control shell is taking
118221 responsibility for restarting the stopped applications. If an application wishes to catch the stop
118222 signals itself, it should first determine their inherited handling states. If a stop signal is being
118223 ignored, the application should continue to ignore it. This is directly analogous to the
118224 recommended handling of SIGINT described in the referenced UNIX Programmer's Manual.

118225 If an application is reading the terminal and has disabled the interpretation of special characters
118226 (by clearing the ISIG flag), the terminal I/O driver will not send SIGTSTP when the suspend
118227 character is typed. Such an application can simulate the effect of the suspend character by
118228 recognizing it and sending SIGTSTP to its process group as the terminal driver would have
118229 done. Note that the signal is sent to the process group, not just to the application itself; this
118230 ensures that other processes in the job also stop. (Note also that other processes in the job could
118231 be children, siblings, or even ancestors.) Applications should not assume that the suspend
118232 character is <control>-Z (or any particular value); they should retrieve the current setting at
118233 startup.

Implementing Job Control Systems

The intent in adding 4.2 BSD-style job control functionality was to adopt the necessary 4.2 BSD programmatic interface with only minimal changes to resolve syntactic or semantic conflicts with System V or to close recognized security holes. The goal was to maximize the ease of providing both conforming implementations and Conforming POSIX.1 Applications.

It is only useful for a process to be affected by job control signals if it is the descendant of a job control shell. Otherwise, there will be nothing that continues the stopped process.

POSIX.1 does not specify how controlling terminal access is affected by a user logging out (that is, by a controlling process terminating). 4.2 BSD uses the *vhangup*( ) function to prevent any access to the controlling terminal through file descriptors opened prior to logout. System V does not prevent controlling terminal access through file descriptors opened prior to logout (except for the case of the special file, **/dev/tty**). Some implementations choose to make processes immune from job control after logout (that is, such processes are always treated as if in the foreground); other implementations continue to enforce foreground/background checks after logout. Therefore, a Conforming POSIX.1 Application should not attempt to access the controlling terminal after logout since such access is unreliable. If an implementation chooses to deny access to a controlling terminal after its controlling process exits, POSIX.1 requires a certain type of behavior (see Controlling Terminal, on page 3491).

Kernel*

See System Call* (on page 3508).

Library Routine*

See System Call* (on page 3508).

Live Process

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0010 [690] is applied.

Logical Device*

Implementation-defined.

Map

The definition of map is included to clarify the usage of mapped pages in the description of the behavior of process memory locking.

Memory-Resident

The term ``memory-resident'' is historically understood to mean that the so-called resident pages are actually present in the physical memory of the computer system and are immune from swapping, paging, copy-on-write faults, and so on. This is the actual intent of POSIX.1-2017 in the process memory locking section for implementations where this is logical. But for some implementations ‡þprimarily mainframes ‡ýactually locking pages into primary storage is not advantageous to other system objectives, such as maximizing throughput. For such implementations, memory locking is a ``hint'' to the implementation that the application wishes to avoid situations that would cause long latencies in accessing memory. Furthermore, there are other implementation-defined issues with minimizing memory access latencies that ``memory residency'' does not address—such as MMU reload faults. The definition attempts to accommodate various implementations while allowing conforming applications to specify to the implementation that they want or need the best memory access times that the implementation

can provide.

Memory Object*

The term ``memory object'' usually implies shared memory. If the object is the same as a filename in the file system name space of the implementation, it is expected that the data written into the memory object be preserved on disk. A memory object may also apply to a physical device on an implementation. In this case, writes to the memory object are sent to the controller for the device and reads result in control registers being returned.

Mount Point*

The directory on which a ``mounted file system'' is mounted. This term, like *mount*( ) and *umount*( ), was not included because it was implementation-defined.

Mounted File System*

See File System (on page 3492).

Multi-Threaded Library

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0011 [625] is applied.

Multi-Threaded Process

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0011 [625] is applied.

Multi-Threaded Program

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0011 [625] is applied.

Name

There are no explicit limits in POSIX.1-2017 on the sizes of names, words (see the definition of word in the Base Definitions volume of POSIX.1-2017), lines, or other objects. However, other implicit limits do apply: shell script lines produced by many of the standard utilities cannot exceed {LINE_MAX} and the sum of exported variables comes under the {ARG_MAX} limit. Historical shells dynamically allocate memory for names and words and parse incoming lines a character at a time. Lines cannot have an arbitrary {LINE_MAX} limit because of historical practice, such as makefiles, where *make* removes the <newline> characters associated with the commands for a target and presents the shell with one very long line. The text on INPUT FILES in XCU Section 1.4 (on page 2336) does allow a shell to run out of memory, but it cannot have arbitrary programming limits.

Native Implementation*

This refers to an implementation of POSIX.1 that interfaces directly to an operating system kernel; see also *hosted implementation*. A similar concept is a native UNIX system, which would be a kernel derived from one of the original UNIX system products.

118309 **Nice Value**

118310 This definition is not intended to suggest that all processes in a system have priorities that are
118311 comparable. Scheduling policy extensions, such as adding realtime priorities, make the notion of
118312 a single underlying priority for all scheduling policies problematic. Some implementations may
118313 implement the features related to *nice* to affect all processes on the system, others to affect just
118314 the general time-sharing activities implied by POSIX.1-2017, and others may have no effect at all.
118315 Because of the use of ``implementation-defined'' in *nice* and *renice*, a wide range of
118316 implementation strategies is possible.

118317 **Open File Description**

118318 An ``open file description'', as it is currently named, describes how a file is being accessed. What
118319 is currently called a ``file descriptor'' is actually just an identifier or ``handle''; it does not
118320 actually describe anything.

118321 The following alternate names were discussed:

118322 For ``open file description'':
118323 ``open instance'', ``file access description'', ``open file information'', and ``file access
118324 information''.

118325 For ``file descriptor'':
118326 ``file handle'', ``file number'' (cf., *fileno*()). Some historical implementations use the term
118327 ``file table entry''.

118328 **Orphaned Process Group**

118329 Historical implementations have a concept of an orphaned process, which is a process whose
118330 parent process has exited. When job control is in use, it is necessary to prevent processes from
118331 being stopped in response to interactions with the terminal after they no longer are controlled by
118332 a job control-cognizant program. Because signals generated by the terminal are sent to a process
118333 group and not to individual processes, and because a signal may be provoked by a process that
118334 is not orphaned, but sent to another process that is orphaned, it is necessary to define an
118335 orphaned process group. The definition assumes that a process group will be manipulated as a
118336 group and that the job control-cognizant process controlling the group is outside of the group
118337 and is the parent of at least one process in the group (so that state changes may be reported via
118338 *waitpid*()). Therefore, a group is considered to be controlled as long as at least one process in the
118339 group has a parent that is outside of the process group, but within the session.

118340 This definition of orphaned process groups ensures that a session leader's process group is
118341 always considered to be orphaned, and thus it is prevented from stopping in response to
118342 terminal signals.

118343 **Page**

118344 The term ``page'' is defined to support the description of the behavior of memory mapping for
118345 shared memory and memory mapped files, and the description of the behavior of process
118346 memory locking. It is not intended to imply that shared memory/file mapping and memory
118347 locking are applicable only to ``paged'' architectures. For the purposes of POSIX.1-2017,
118348 whatever the granularity on which an architecture supports mapping or locking, this is
118349 considered to be a ``page'' . If an architecture cannot support the memory mapping or locking
118350 functions specified by POSIX.1-2017 on any granularity, then these options will not be
118351 implemented on the architecture.

118352 **Pathname**

118353 Pathnames historically allowed all bytes except for the <slash> and <NUL> characters. For
118354 compatibility with existing file systems, this usage is maintained throughout the standard by
118355 noting that a pathname need not be a valid character string in all locales. However, the
118356 properties of the portable filename character set are such that a pathname using only those
118357 characters and the <slash> is portable in all locales as a character string.

118358 **Passwd File***

118359 Implementation-defined; see User Database (on page 3510).

118360 **Parent Directory**

118361 There may be more than one directory entry pointing to a given directory in some
118362 implementations. The wording here identifies that exactly one of those is the parent directory. In
118363 pathname resolution, dot-dot is identified as the way that the unique directory is identified.
118364 (That is, the parent directory is the one to which dot-dot points.) In the case of a remote file
118365 system, if the same file system is mounted several times, it would appear as if they were distinct
118366 file systems (with interesting synchronization properties).

118367 **Pipe**

118368 It proved convenient to define a pipe as a special case of a FIFO, even though historically the
118369 latter was not introduced until System III and does not exist at all in 4.3 BSD.

118370 **Portable Filename**

118371 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0012 [584] is applied.

118372 **Portable Filename Character Set**

118373 The encoding of this character set is not specified—specifically, ASCII is not required. But the
118374 implementation must provide a unique character code for each of the printable graphics
118375 specified by POSIX.1; see also Section A.4.7 (on page 3512).

118376 Situations where characters beyond the portable filename character set (or historically ASCII or
118377 the ISO/IEC 646:1991 standard) would be used (in a context where the portable filename
118378 character set or the ISO/IEC 646:1991 standard is required by POSIX.1) are expected to be
118379 common. Although such a situation renders the use technically non-compliant, mutual
118380 agreement among the users of an extended character set will make such use portable between
118381 those users. Such a mutual agreement could be formalized as an optional extension to POSIX.1.
118382 (Making it required would eliminate too many possible systems, as even those systems using the
118383 ISO/IEC 646:1991 standard as a base character set extend their character sets for Western
118384 Europe and the rest of the world in different ways.)

118385 Nothing in POSIX.1 is intended to preclude the use of extended characters where interchange is
118386 not required or where mutual agreement is obtained. It has been suggested that in several places
118387 ``should'' be used instead of ``shall''. Because (in the worst case) use of any character beyond the
118388 portable filename character set would render the program or data not portable to all possible
118389 systems, no extensions are permitted in this context.

118390 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0013 [584] is applied.

Process

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0014 [690] is applied.

Process Lifetime

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/5 is applied, adding *fork*( ), *posix_spawn*( ), *posix_spawnp*( ), and *vfork*( ) to the list of functions.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0014 [690] is applied.

Process Termination

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/6 is applied, rewording the definition to address the ``passive exit'' on termination of the last thread or the *_Exit*( ) function.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0014 [690] is applied.

Regular File

POSIX.1 does not intend to preclude the addition of structuring data (for example, record lengths) in the file, as long as such data is not visible to an application that uses the features described in POSIX.1.

Root Directory

This definition permits the operation of *chroot*( ), even though that function is not in POSIX.1; see also Section A.4.6 (on page 3512).

Root File System*

Implementation-defined.

Root of a File System*

Implementation-defined; see Mount Point* (on page 3498).

Signal

The definition implies a double meaning for the term. Although a signal is an event, common usage implies that a signal is an identifier of the class of event.

Single-Threaded Process

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0011 [625] is applied.

Single-Threaded Program

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0011 [625] is applied.

Source Code

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0015 [896] is applied.

Superuser*

This concept, with great historical significance to UNIX system users, has been replaced with the notion of appropriate privileges.

Supplementary Group ID

The POSIX.1-1990 standard is inconsistent in its treatment of supplementary groups. The definition of supplementary group ID explicitly permits the effective group ID to be included in the set, but wording in the description of the *setuid*() and *setgid*() functions states: ``Any supplementary group IDs of the calling process remain unchanged by these function calls''. In the case of *setgid*() this contradicts that definition. In addition, some felt that the unspecified behavior in the definition of supplementary group IDs adds unnecessary portability problems. The standard developers considered several solutions to this problem:

1. Reword the description of *setgid*() to permit it to change the supplementary group IDs to reflect the new effective group ID. A problem with this is that it adds more ``may''s to the wording and does not address the portability problems of this optional behavior.
2. Mandate the inclusion of the effective group ID in the supplementary set (giving {NGROUPS_MAX} a minimum value of 1). This is the behavior of 4.4 BSD. In that system, the effective group ID is the first element of the array of supplementary group IDs (there is no separate copy stored, and changes to the effective group ID are made only in the supplementary group set). By convention, the initial value of the effective group ID is duplicated elsewhere in the array so that the initial value is not lost when executing a set-group-ID program.
3. Change the definition of supplementary group ID to exclude the effective group ID and specify that the effective group ID does not change the set of supplementary group IDs. This is the behavior of 4.2 BSD, 4.3 BSD, and System V Release 4.
4. Change the definition of supplementary group ID to exclude the effective group ID, and require that *getgroups*() return the union of the effective group ID and the supplementary group IDs.
5. Change the definition of {NGROUPS_MAX} to be one more than the number of supplementary group IDs, so it continues to be the number of values returned by *getgroups*() and existing applications continue to work. This alternative is effectively the same as the second (and might actually have the same implementation).

The standard developers decided to permit either 2 or 3. The effective group ID is orthogonal to the set of supplementary group IDs, and it is implementation-defined whether *getgroups*() returns this. If the effective group ID is returned with the set of supplementary group IDs, then all changes to the effective group ID affect the supplementary group set returned by *getgroups*(). It is permissible to eliminate duplicates from the list returned by *getgroups*(). However, if a group ID is contained in the set of supplementary group IDs, setting the group ID to that value and then to a different value should not remove that value from the supplementary group IDs.

The definition of supplementary group IDs has been changed to not include the effective group ID. This simplifies permanent rationale and makes the relevant functions easier to understand. The *getgroups*() function has been modified so that it can, on an implementation-defined basis, return the effective group ID. By making this change, functions that modify the effective group ID do not need to discuss adding to the supplementary group list; the only view into the supplementary group list that the application developer has is through the *getgroups*() function.

118465 **Symbolic Constant**

118466 Earlier versions of this standard used a variety of terms other than ``macro'' for many of the
118467 constants defined in headers, and it was not clear in which of these cases they were required to
118468 be macros or not, or to be pre-processor constants (i.e., usable in **#if**) or not. In cases where the
118469 symbols had a reserved prefix or suffix, there was often inconsistency between whether the
118470 prefix/suffix was reserved only for macros or for any use, and whether the term ``macro'' or a
118471 different term was used in the descriptions of the symbols. There were also some unintentional
118472 differences from the ISO C standard.

118473 One of the most commonly used terms was ``symbolic constant''. This has now been designated
118474 as the default term to be used wherever appropriate, and a formal definition of the term has
118475 been added giving the exact requirements for symbols that are described as symbolic constants.

118476 The standard developers have performed a major rationalization of the header descriptions of
118477 symbols with constant values according to the following policy:

118478 Where symbols are from the ISO C standard, the wording from the ISO C standard (or
118479 equivalent, in cases where the exact wording is not appropriate) is used to describe them.

118480 For all other constants, the first choice is to use ``symbolic constant'' when the
118481 requirements for the symbol are a reasonably close fit with those of the term.

118482 The description of the symbol can override individual requirements for symbolic
118483 constants; e.g., to specify a non-integer type, or to add a requirement that the symbol is
118484 usable in **#if** preprocessor directives.

118485 When neither of the above apply, the exact requirements are stated in the description.
118486 (Note that macros are not required to be usable in **#if**, or even to expand to constant
118487 expressions, unless explicitly stated.)

118488 In cases where there is a reserved prefix or suffix, if the symbol(s) with that prefix/suffix
118489 are from the ISO C standard and are required to be macros, or if the symbol is required to
118490 be usable in **#if**, then the prefix/suffix is reserved for use only as macros. If the symbol(s)
118491 are ``symbolic constants'' and not required to be usable in **#if**, the prefix/suffix is reserved
118492 for any use except in a few special cases.

118493 Where a constant is required to be a macro but is also allowed to be another type of constant
118494 such as an enumeration constant, on implementations which do define it as another type of
118495 constant the macro is typically defined as follows:

118496 `#define macro_name macro_name`

118497 This allows applications to use **#ifdef**, etc. to determine whether the macro is defined, but the
118498 macro is not usable in **#if** preprocessor directives because the preprocessor will treat the
118499 unexpanded word *macro_name* as having the value zero.

118500 **Symbolic Link**

118501 Earlier versions of this standard did not require symbolic links to have attributes such as
118502 ownership and a file serial number. This was because the 4.4 BSD implementation did not have
118503 them, and it was expected that other implementations may wish to do the same. However,
118504 experience with 4.4 BSD has shown that symbolic links implemented in this way cause problems
118505 for users and application developers, and later BSD systems have reverted to using *inode*s to
118506 implement symbolic links. Allowing no-*inode* symbolic links also caused problems in the
118507 standard. For example, leaving the *st_ino* value for symbolic links unspecified meant that the
118508 common technique of comparing the *st_dev* and *st_ino* values for two pathnames to see if they
118509 refer to the same file could only be used with *stat*() in conforming applications and not with
118510 *lstat*(). The standard now requires symbolic links to have meaningful values for the same **struct**

stat fields as regular files, except for the file mode bits in *st_mode*. Historically, the file mode bits were unused (the contents of a symbolic link could always be read), but implementations differed as to whether the file mode bits (as returned in *st_mode* or reported by *ls* **–l**) were set according to the *umask* or just to a fixed value such as 0777. Accordingly, the standard requires the file mode bits to be ignored by *readlink*() and when a symbolic link is followed during pathname resolution, but leaves the corresponding part of the value returned in *st_mode* unspecified.

Historical implementations were followed when determining which interfaces should apply to symbolic links. Interfaces that historically followed symbolic links include *chmod*(), *stat*(), and *utime*(). Interfaces that historically did not follow symbolic links include *lstat*(), *rename*(), *remove*(), *rmdir*(), and *unlink*(). For *chown*() and *link*(), historical implementations differed. POSIX.1-2017 inherited the *lchown*() function from the Single UNIX Specification, Version 2, and therefore requires *chown*() to follow symbolic links. Earlier versions of this standard required *link*() to follow symbolic links, but with the addition of the *linkat*() function (which has a flag to indicate whether to follow symbolic links), both behaviors are now allowed for *link*().

When the final component of a pathname is a symbolic link, the standard requires that a trailing <slash> causes the link to be followed. This is the behavior of historical implementations. For example, for **/a/b** and **/a/b/**, if **/a/b** is a symbolic link to a directory, then **/a/b** refers to the symbolic link, and **/a/b/** refers to the directory to which the symbolic link points.

Because a symbolic link and its referenced object coexist in the file system name space, confusion can arise in distinguishing between the link itself and the referenced object. Historically, utilities and system calls have adopted their own link following conventions in a somewhat *ad hoc* fashion. Rules for a uniform approach are outlined here, although historical practice has been adhered to as much as was possible. To promote consistent system use, user-written utilities are encouraged to follow these same rules.

Symbolic links are handled either by operating on the link itself, or by operating on the object referenced by the link. In the latter case, an application or system call is said to ``follow'' the link. Symbolic links may reference other symbolic links, in which case links are dereferenced until an object that is not a symbolic link is found, a symbolic link that references a file that does not exist is found, or a loop is detected. (Current implementations do not detect loops, but have a limit on the number of symbolic links that they will dereference before declaring it an error.)

There are four domains for which default symbolic link policy is established in a system. In almost all cases, there are utility options that override this default behavior. The four domains are as follows:

1. Symbolic links specified to system calls that take pathname arguments
2. Symbolic links specified as command line pathname arguments to utilities that are not performing a traversal of a file hierarchy
3. Symbolic links referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy
4. Symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy

118552 *First Domain*

118553 The first domain is considered in earlier rationale.

118554 *Second Domain*

118555 The reason this category is restricted to utilities that are not traversing the file hierarchy is that
118556 some standard utilities take an option that specifies a hierarchical traversal, but by default
118557 operate on the arguments themselves. Generally, users specifying the option for a file hierarchy
118558 traversal wish to operate on a single, physical hierarchy, and therefore symbolic links, which
118559 may reference files outside of the hierarchy, are ignored. For example, *chown owner file* is a
118560 different operation from the same command with the **−R** option specified. In this example, the
118561 behavior of the command *chown owner file* is described here, while the behavior of the command
118562 *chown* **−R** *owner file* is described in the third and fourth domains.

118563 The general rule is that the utilities in this category follow symbolic links named as arguments.

118564 Exceptions in the second domain are:

118565 The *mv* and *rm* utilities do not follow symbolic links named as arguments, but respectively
118566 attempt to rename or delete them.

118567 The *ls* utility is also an exception to this rule. For compatibility with historical systems,
118568 when the **−R** option is not specified, the *ls* utility follows symbolic links named as
118569 arguments if the **−L** option is specified or if the **−F**, **−d**, or **−l** options are not specified. (If
118570 the **−L** option is specified, *ls* always follows symbolic links; it is the only utility where the
118571 **−L** option affects its behavior even though a tree walk is not being performed.)

118572 All other standard utilities, when not traversing a file hierarchy, always follow symbolic links
118573 named as arguments.

118574 Historical practice is that the **−h** option is specified if standard utilities are to act upon symbolic
118575 links instead of upon their targets. Examples of commands that have historically had a **−h** option
118576 for this purpose are the *chgrp*, *chown*, *file*, and *test* utilities.

118577 *Third Domain*

118578 The third domain is symbolic links, referencing files not of type directory, specified to utilities
118579 that are performing a traversal of a file hierarchy. (This includes symbolic links specified as
118580 command line pathname arguments or encountered during the traversal.)

118581 The intention of the Shell and Utilities volume of POSIX.1-2017 is that the operation that the
118582 utility is performing is applied to the symbolic link itself, if that operation is applicable to
118583 symbolic links. If the operation is not applicable to symbolic links, the symbolic link should be
118584 ignored. Specifically, by default, no change should be made to the file referenced by the symbolic
118585 link.

118586 *Fourth Domain*

118587 The fourth domain is symbolic links referencing files of type directory, specified to utilities that
118588 are performing a traversal of a file hierarchy. (This includes symbolic links specified as
118589 command line pathname arguments or encountered during the traversal.)

118590 Most standard utilities do not, by default, indirect into the file hierarchy referenced by the
118591 symbolic link. (The Shell and Utilities volume of POSIX.1-2017 uses the informal term ``physical
118592 walk'' to describe this case. The case where the utility does indirect through the symbolic link is
118593 termed a ``logical walk''.)

118594 There are three reasons for the default to be a physical walk:

1. With very few exceptions, a physical walk has been the historical default on UNIX systems supporting symbolic links. Because some utilities (that is, *rm*) must default to a physical walk, regardless, changing historical practice in this regard would be confusing to users and needlessly incompatible.
2. For systems where symbolic links have the historical file attributes (that is, *owner*, *group*, *mode*), defaulting to a logical traversal would require the addition of a new option to the commands to modify the attributes of the link itself. This is painful and more complex than the alternatives.
3. There is a security issue with defaulting to a logical walk. Historically, the command *chown* **−R** *user file* has been safe for the superuser because *setuid* and *setgid* bits were lost when the ownership of the file was changed. If the walk were logical, changing ownership would no longer be safe because a user might have inserted a symbolic link pointing to any file in the tree. Again, this would necessitate the addition of an option to the commands doing hierarchy traversal to not indirect through the symbolic links, and historical scripts doing recursive walks would instantly become security problems. While this is mostly an issue for system administrators, it is preferable to not have different defaults for different classes of users.

However, the standard developers agreed to leave it unspecified to achieve consensus.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line, regardless of the type of file they reference, by specifying the **−H** (for half logical) option. This option is intended to make the command line name space look like the logical name space.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line as well as any symbolic links encountered during the traversal, regardless of the type of file they reference, by specifying the **−L** (for logical) option. This option is intended to make the entire name space look like the logical name space.

For consistency, implementors are encouraged to use the **−P** (for ``physical'') flag to specify the physical walk in utilities that do logical walks by default for whatever reason.

When one or more of the **−H**, **−L**, and **−P** flags can be specified, the last one specified determines the behavior of the utility. This permits users to alias commands so that the default behavior is a logical walk and then override that behavior on the command line.

Exceptions in the Third and Fourth Domains

The *ls* and *rm* utilities are exceptions to these rules. The *rm* utility never follows symbolic links and does not support the **−H**, **−L**, or **−P** options. Some historical versions of *ls* always followed symbolic links given on the command line whether the **−L** option was specified or not. Historical versions of *ls* did not support the **−H** option. In POSIX.1-2017, unless one of the **−H** or **−L** options is specified, the *ls* utility only follows symbolic links to directories that are given as operands. The *ls* utility does not support the **−P** option.

The Shell and Utilities volume of POSIX.1-2017 requires that the standard utilities *ls*, *find*, and *pax* detect infinite loops when doing logical walks; that is, a directory, or more commonly a symbolic link, that refers to an ancestor in the current file hierarchy. If the file system itself is corrupted, causing the infinite loop, it may be impossible to recover. Because *find* and *ls* are often used in system administration and security applications, they should attempt to recover and continue as best as they can. The *pax* utility should terminate because the archive it was creating is by definition corrupted. Other, less vital, utilities should probably simply terminate as well. Implementations are strongly encouraged to detect infinite loops in all utilities.

Historical practice is shown in Table A-1. The heading **SVID3** stands for the Third Edition of the System V Interface Definition.

Historically, several shells have had built-in versions of the *pwd* utility. In some of these shells, *pwd* reported the physical path, and in others, the logical path. Implementations of the shell corresponding to POSIX.1-2017 must report the logical path by default.

The *cd* command is required, by default, to treat the filename dot-dot logically. Implementors are required to support the **−P** flag in *cd* so that users can have their current environment handled physically. In 4.3 BSD, *chgrp* during tree traversal changed the group of the symbolic link, not the target. Symbolic links in 4.4 BSD did not have *owner*, *group*, *mode*, or other standard UNIX system file attributes.

Table A-1 Historical Practice for Symbolic Links

Utility	SVID3	4.3 BSD	4.4 BSD	POSIX	Comments
cd				**−L**	Treat "**. .**" logically.
cd				**−P**	Treat "**. .**" physically.
chgrp			**−H**	**−H**	Follow command line symlinks.
chgrp			**−h**	**−L**	Follow symlinks.
chgrp	**−h**			**−h**	Affect the symlink.
chmod					Affect the symlink.
chmod			**−H**		Follow command line symlinks.
chmod			**−h**		Follow symlinks.
chown			**−H**	**−H**	Follow command line symlinks.
chown			**−h**	**−L**	Follow symlinks.
chown	**−h**			**−h**	Affect the symlink.
cp			**−H**	**−H**	Follow command line symlinks.
cp			**−h**	**−L**	Follow symlinks.
cpio	**−L**		**−L**		Follow symlinks.
du			**−H**	**−H**	Follow command line symlinks.
du			**−h**	**−L**	Follow symlinks.
file	**−h**			**−h**	Affect the symlink.
find			**−H**	**−H**	Follow command line symlinks.
find			**−h**	**−L**	Follow symlinks.
find	**−follow**		**−follow**		Follow symlinks.
ln	**−s**	**−s**	**−s**	**−s**	Create a symbolic link.
ls	**−L**	**−L**	**−L**	**−L**	Follow symlinks.
ls				**−H**	Follow command line symlinks.
mv					Operates on the symlink.
pax			**−H**	**−H**	Follow command line symlinks.
pax			**−h**	**−L**	Follow symlinks.
pwd				**−L**	Printed path may contain symlinks.
pwd				**−P**	Printed path will not contain symlinks.
rm					Operates on the symlink.
tar			**−H**		Follow command line symlinks.
tar		**−h**	**−h**		Follow symlinks.
test	**−h**		**−h**	**−h**	Affect the symlink.

Synchronously-Generated Signal

Those signals that may be generated synchronously include SIGABRT, SIGBUS, SIGILL, SIGFPE, SIGPIPE, and SIGSEGV.

Any signal sent via the *raise*() function or a *kill*() function targeting the current process is also considered synchronous.

System Call*

The distinction between a ``system call'' and a ``library routine'' is an implementation detail that may differ between implementations and has thus been excluded from POSIX.1.

See ``Interface, Not Implementation'' in the Preface.

System Console

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/7 is applied, changing from ``An implementation-defined device'' to ``A device''.

System Databases

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/9 is applied, rewording the definition to reference the existing definitions for ``group database'' and ``user database''.

System Process

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/8 is applied, rewording the definition to remove the requirement for an implementation to define the object.

System Reboot

A ``system reboot'' is an event initiated by an unspecified circumstance that causes all processes (other than special system processes) to be terminated in an implementation-defined manner, after which any changes to the state and contents of files created or written to by a Conforming POSIX.1 Application prior to the event are implementation-defined.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/10 is applied, changing ``An implementation-defined sequence of events'' to ``An unspecified sequence of events''.

Synchronized I/O Data (and File) Integrity Completion

These terms specify that for synchronized read operations, pending writes must be successfully completed before the read operation can complete. This is motivated by two circumstances. Firstly, when synchronizing processes can access the same file, but not share common buffers (such as for a remote file system), this requirement permits the reading process to guarantee that it can read data written remotely. Secondly, having data written synchronously is insufficient to guarantee the order with respect to a subsequent write by a reading process, and thus this extra read semantic is necessary.

Text File

The term ``text file'' does not prevent the inclusion of control or other non-printable characters (other than NUL). Therefore, standard utilities that list text files as inputs or outputs are either able to process the special characters or they explicitly describe their limitations within their individual descriptions. The definition of ``text file'' has caused controversy. The only difference between text and binary files is that text files have lines of less than {LINE_MAX} bytes, with no NUL characters, each terminated by a <newline>. The definition allows a file with a single <newline>, or a totally empty file, to be called a text file. If a file ends with an incomplete line it is not strictly a text file by this definition. The <newline> referred to in POSIX.1-2017 is not some generic line separator, but a single character; files created on systems where they use multiple characters for ends of lines are not portable to all conforming systems without some translation process unspecified by POSIX.1-2017.

Thread

POSIX.1-2017 defines a thread to be a flow of control within a process. Each thread has a minimal amount of private state; most of the state associated with a process is shared among all of the threads in the process. While most multi-thread extensions to POSIX have taken this approach, others have made different decisions.

Note: The choice to put threads within a process does not constrain implementations to implement threads in that manner. However, all functions have to behave as though threads share the indicated state information with the process from which they were created.

Threads need to share resources in order to cooperate. Memory has to be widely shared between threads in order for the threads to cooperate at a fine level of granularity. Threads keep data structures and the locks protecting those data structures in shared memory. For a data structure to be usefully shared between threads, such structures should not refer to any data that can only be interpreted meaningfully by a single thread. Thus, any system resources that might be referred to in data structures need to be shared between all threads. File descriptors, pathnames, and pointers to stack variables are all things that programmers want to share between their threads. Thus, the file descriptor table, the root directory, the current working directory, and the address space have to be shared.

Library implementations are possible as long as the effective behavior is as if system services invoked by one thread do not suspend other threads. This may be difficult for some library implementations on systems that do not provide asynchronous facilities.

See Section B.2.9 (on page 3633) for additional rationale.

Thread ID

See Section B.2.9.2 (on page 3650) for additional rationale.

Thread-Safe Function

All functions required by POSIX.1-2017 need to be thread-safe; see Section A.4.18 (on page 3520) and Section B.2.9.1 (on page 3647) for additional rationale.

User Database

There are no references in POSIX.1-2017 to a ``passwd file'' or a ``group file'', and there is no requirement that the *group* or *passwd* databases be kept in files containing editable text. Many large timesharing systems use *passwd* databases that are hashed for speed. Certain security classifications prohibit certain information in the *passwd* database from being publicly readable.

The term ``encoded'' is used instead of ``encrypted'' in order to avoid the implementation connotations (such as reversibility or use of a particular algorithm) of the latter term.

The *getgrent*(), *setgrent*(), *endgrent*(), *getpwent*(), *setpwent*(), and *endpwent*() functions are not included as part of the base standard because they provide a linear database search capability that is not generally useful (the *getpwuid*(), *getpwnam*(), *getgrgid*(), and *getgrnam*() functions are provided for keyed lookup) and because in certain distributed systems, especially those with different authentication domains, it may not be possible or desirable to provide an application with the ability to browse the system databases indiscriminately. They are provided on XSI-conformant systems due to their historical usage by many existing applications.

A change from historical implementations is that the structures used by these functions have fields of the types **gid_t** and **uid_t**, which are required to be defined in the **<sys/types.h>** header. POSIX.1-2017 requires implementations to ensure that these types are defined by inclusion of **<grp.h>** and **<pwd.h>**, respectively, without imposing any name space pollution or errors from redefinition of types.

POSIX.1-2017 is silent about the content of the strings containing user or group names. These could be digit strings. POSIX.1-2017 is also silent as to whether such digit strings bear any relationship to the corresponding (numeric) user or group ID.

Database Access

The thread-safe versions of the user and group database access functions return values in user-supplied buffers instead of possibly using static data areas that may be overwritten by each call.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/11 is applied, removing the words ``of implementation-defined format''.

User ID

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0016 [511] is applied.

User Name

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0017 [584] is applied.

Virtual Processor*

The term ``virtual processor'' was chosen as a neutral term describing all kernel-level schedulable entities, such as processes, Mach tasks, or lightweight processes. Implementing threads using multiple processes as virtual processors, or implementing multiplexed threads above a virtual processor layer, should be possible, provided some mechanism has also been implemented for sharing state between processes or virtual processors. Many systems may also wish to provide implementations of threads on systems providing ``shared processes'' or ``variable-weight processes''. It was felt that exposing such implementation details would severely limit the type of systems upon which the threads interface could be supported and prevent certain types of valid implementations. It was also determined that a virtual processor interface was out of the scope of the Rationale (Informative) volume of POSIX.1-2017.

XSI

This is included to allow POSIX.1-2017 to be adopted as an IEEE standard and an Open Group Standard, serving both the POSIX and the Single UNIX Specification in a core set of volumes.

The term ``XSI'' has been used for 10 years in connection with the XPG series and the first and second versions of the base volumes of the Single UNIX Specification. The XSI margin code was introduced to denote the extended or more restrictive semantics beyond POSIX that are applicable to UNIX systems.

Zombie Process

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0018 [690] is applied.

A.4 General Concepts

The general concepts are similar in nature to the definitions section, with the exception that a term defined in general concepts can contain normative requirements.

A.4.1 Concurrent Execution

There is no additional rationale provided for this section.

A.4.2 Default Initialization

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0019 [934] is applied.

A.4.3 Directory Protection

There is no additional rationale provided for this section.

A.4.4 Extended Security Controls

Allowing an implementation to define extended security controls enables the use of POSIX.1-2017 in environments that require different or more rigorous security than that provided in POSIX.1. Extensions are allowed in two areas: privilege and file access permissions. The semantics of these areas have been defined to permit extensions with reasonable, but not exact, compatibility with all existing practices. For example, the elimination of the superuser definition precludes identifying a process as privileged or not by virtue of its effective user ID.

A.4.5 File Access Permissions

A process should not try to anticipate the result of an attempt to access data by *a priori* use of these rules. Rather, it should make the attempt to access data and examine the return value (and possibly *errno* as well), or use *access*( ). An implementation may include other security mechanisms in addition to those specified in POSIX.1, and an access attempt may fail because of those additional mechanisms, even though it would succeed according to the rules given in this section. (For example, the user's security level might be lower than that of the object of the access attempt.) The supplementary group IDs provide another reason for a process to not

attempt to anticipate the result of an access attempt.

Since the current standard does not specify a method for opening a directory for searching, it is unspecified whether search permission on the *fd* argument to *openat*( ) and related functions is based on whether the directory was opened with search mode or on the current permissions allowed by the directory at the time a search is performed. When there is existing practice that supports opening directories for searching, it is expected that these functions will be modified to specify that the search permissions will be granted based on the file access modes of the directory's file descriptor identified by *fd*, and not on the mode of the directory at the time the directory is searched.

A.4.6 File Hierarchy

Though the file hierarchy is commonly regarded to be a tree, POSIX.1 does not define it as such for three reasons:

1. Links may join branches.
2. In some network implementations, there may be no single absolute root directory; see *pathname resolution*.
3. With symbolic links, the file system need not be a tree or even a directed acyclic graph.

A.4.7 Filenames

Historically, certain filenames and pathnames have been reserved. This list includes **core**, **/etc/passwd**, and so on. Conforming applications should avoid these.

Most historical implementations prohibit case folding in filenames; that is, treating uppercase and lowercase alphabetic characters as identical. However, some consider case folding desirable:

For user convenience

For ease-of-implementation of the POSIX.1 interface as a hosted system on some popular operating systems

Variants, such as maintaining case distinctions in filenames, but ignoring them in comparisons, have been suggested. Methods of allowing escaped characters of the case opposite the default have been proposed.

Many reasons have been expressed for not allowing case folding, including:

No solid evidence has been produced as to whether case-sensitivity or case-insensitivity is more convenient for users.

Making case-insensitivity a POSIX.1 implementation option would be worse than either having it or not having it, because:

- No confusion would be caused among users.
- Application developers would have to account for both cases in their code.
- POSIX.1 implementors would still have other problems with native file systems, such as short or otherwise constrained filenames or pathnames, and the lack of hierarchical directory structure.

Case folding is not easily defined in many European languages, both because many of them use characters outside the US ASCII alphabetic set, and because:

118871 In Spanish, the digraph "ll" is considered to be a single letter, the capitalized form
118872 of which may be either "Ll" or "LL", depending on context.

118873 In French, the capitalized form of a letter with an accent may or may not retain the
118874 accent, depending on the country in which it is written.

118875 In German, the sharp ess may be represented as a single character resembling a
118876 Greek beta (β) in lowercase, but as the digraph "SS" in uppercase.

118877 In Greek, there are several lowercase forms of some letters; the one to use depends on
118878 its position in the word. Arabic has similar rules.

118879 Many East Asian languages, including Japanese, Chinese, and Korean, do not distinguish
118880 case and are sometimes encoded in character sets that use more than one byte per
118881 character.

118882 Multiple character codes may be used on the same machine simultaneously. There are
118883 several ISO character sets for European alphabets. In Japan, several Japanese character
118884 codes are commonly used together, sometimes even in filenames; this is evidently also the
118885 case in China. To handle case insensitivity, the kernel would have to at least be able to
118886 distinguish for which character sets the concept made sense.

118887 The file system implementation historically deals only with bytes, not with characters.
118888 Limitations on valid encodings ensure that the byte sequences for the <slash> character,
118889 <period> character, and <NUL> character will not be confused with any other character in
118890 any locale. However, there exist common single-shift encodings where other single-byte
118891 characters from the portable filename character set can also occur as a subset of a multi-
118892 byte character, making case folding of portable filename bytes dependent on the context of
118893 whether a shift-state is active.

118894 The purpose of POSIX.1 is to standardize the common, existing definition, not to change it.
118895 Mandating case-insensitivity would make all historical implementations non-standard.

118896 Not only the interface, but also application programs would need to change, counter to the
118897 purpose of having minimal changes to existing application code.

118898 At least one of the original developers of the UNIX system has expressed objection in the
118899 strongest terms to either requiring case-insensitivity or making it an option, mostly on the
118900 basis that POSIX.1 should not hinder portability of application programs across related
118901 implementations in order to allow compatibility with unrelated operating systems.

118902 Two proposals were entertained regarding case folding in filenames:

118903 1. Remove all wording that previously permitted case folding.

118904 Rationale Case folding is inconsistent with the portable filename character set and
118905 filename definitions (all bytes except <slash> and null). No known
118906 implementations allowing all bytes except <slash> and null also do case
118907 folding.

118908 2. Change ``though this practice is not recommended:'' to ``although this practice is strongly
118909 discouraged.''

118910 Rationale If case folding must be included in POSIX.1, the wording should be stronger
118911 to discourage the practice.

118912 The consensus selected the first proposal. Otherwise, a conforming application would have to
118913 assume that case folding would occur when it was not wanted, but that it would not occur when
118914 it was wanted.

A.4.8 Filename Portability

Filenames should be constructed from the portable filename character set because the use of other characters can be confusing or ambiguous in certain contexts. (For example, the use of a <colon> (':') in a pathname could cause ambiguity if that pathname were included in a *PATH* definition.)

The constraint on use of the <hyphen-minus> character as the first character of a portable filename is a constraint on application behavior and not on implementations, since applications might not work as expected when such a filename is passed as a command line argument.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0020 [584] is applied.

A.4.9 File Times Update

This section reflects the actions of historical implementations. The times are not updated immediately, but are only marked for update by the functions. An implementation may update these times immediately.

The accuracy of the time update values is intentionally left unspecified so that systems can control the bandwidth of a possible covert channel.

The wording was carefully chosen to make it clear that there is no requirement that the conformance document contain information that might incidentally affect file timestamps. Any function that performs pathname resolution might update several last data access timestamps. Functions such as *getpwnam*() and *getgrnam*() might update the last data access timestamp of some specific file or files. It is intended that these are not required to be documented in the conformance document, but they should appear in the system documentation.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0021 [626] is applied.

A.4.10 Host and Network Byte Order

There is no additional rationale provided for this section.

A.4.11 Measurement of Execution Time

The methods used to measure the execution time of processes and threads, and the precision of these measurements, may vary considerably depending on the software architecture of the implementation, and on the underlying hardware. Implementations can also make tradeoffs between the scheduling overhead and the precision of the execution time measurements. POSIX.1-2017 does not impose any requirement on the accuracy of the execution time; it instead specifies that the measurement mechanism and its precision are implementation-defined.

A.4.12 Memory Synchronization

In older multi-processors, access to memory by the processors was strictly multiplexed. This meant that a processor executing program code interrogates or modifies memory in the order specified by the code and that all the memory operation of all the processors in the system appear to happen in some global order, though the operation histories of different processors are interleaved arbitrarily. The memory operations of such machines are said to be sequentially consistent. In this environment, threads can synchronize using ordinary memory operations. For example, a producer thread and a consumer thread can synchronize access to a circular data buffer as follows:

```
int rdptr = 0;
int wrptr = 0;
data_t buf[BUFSIZE];

Thread 1:
    while (work_to_do) {
        int next;

        buf[wrptr] = produce();
        next = (wrptr + 1) % BUFSIZE;
        while (rdptr == next)
            ;
        wrptr = next;
}

Thread 2:
    while (work_to_do) {
        while (rdptr == wrptr)
            ;
        consume(buf[rdptr]);
        rdptr = (rdptr + 1) % BUFSIZE;
    }
```

In modern multi-processors, these conditions are relaxed to achieve greater performance. If one processor stores values in location A and then location B, then other processors loading data from location B and then location A may see the new value of B but the old value of A. The memory operations of such machines are said to be weakly ordered. On these machines, the circular buffer technique shown in the example will fail because the consumer may see the new value of *wrptr* but the old value of the data in the buffer. In such machines, synchronization can only be achieved through the use of special instructions that enforce an order on memory operations. Most high-level language compilers only generate ordinary memory operations to take advantage of the increased performance. They usually cannot determine when memory operation order is important and generate the special ordering instructions. Instead, they rely on the programmer to use synchronization primitives correctly to ensure that modifications to a location in memory are ordered with respect to modifications and/or access to the same location in other threads. Access to read-only data need not be synchronized. The resulting program is said to be data race-free.

Synchronization is still important even when accessing a single primitive variable (for example, an integer). On machines where the integer may not be aligned to the bus data width or be larger than the data width, a single memory load may require multiple memory cycles. This means that it may be possible for some parts of the integer to have an old value while other parts have a newer value. On some processor architectures this cannot happen, but portable programs cannot rely on this.

In summary, a portable multi-threaded program, or a multi-process program that shares

writable memory between processes, has to use the synchronization primitives to synchronize data access. It cannot rely on modifications to memory being observed by other threads in the order written in the application or even on modification of a single variable being seen atomically.

Conforming applications may only use the functions listed to synchronize threads of control with respect to memory access. There are many other candidates for functions that might also be used. Examples are: signal sending and reception, or pipe writing and reading. In general, any function that allows one thread of control to wait for an action caused by another thread of control is a candidate. POSIX.1-2017 does not require these additional functions to synchronize memory access since this would imply the following:

> All these functions would have to be recognized by advanced compilation systems so that memory operations and calls to these functions are not reordered by optimization.
>
> All these functions would potentially have to have memory synchronization instructions added, depending on the particular machine.
>
> The additional functions complicate the model of how memory is synchronized and make automatic data race detection techniques impractical.

Formal definitions of the memory model were rejected as unreadable by the vast majority of programmers. In addition, most of the formal work in the literature has concentrated on the memory as provided by the hardware as opposed to the application programmer through the compiler and runtime system. It was believed that a simple statement intuitive to most programmers would be most effective. POSIX.1-2017 defines functions that can be used to synchronize access to memory, but it leaves open exactly how one relates those functions to the semantics of each function as specified elsewhere in POSIX.1-2017. POSIX.1-2017 also does not make a formal specification of the partial ordering in time that the functions can impose, as that is implied in the description of the semantics of each function. It simply states that the programmer has to ensure that modifications do not occur ``simultaneously'' with other access to a memory location.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/4 is applied, adding a new paragraph beneath the table of functions: ``The *pthread_once*() function shall synchronize memory for the first call in each thread for a given **pthread_once_t** object.''.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0022 [863] is applied.

A.4.13 Pathname Resolution

It is necessary to differentiate between the definition of pathname and the concept of pathname resolution with respect to the handling of trailing <slash> characters. By specifying the behavior here, it is not possible to provide an implementation that is conforming but extends all interfaces that handle pathnames to also handle strings that are not legal pathnames (because they have trailing <slash> characters).

Pathnames that end with one or more trailing <slash> characters must refer to directory paths. Earlier versions of this standard were not specific about the distinction between trailing <slash> characters on files and directories, and both were permitted.

Two types of implementation have been prevalent; those that ignored trailing <slash> characters on all pathnames regardless, and those that permitted them only on existing directories.

An earlier version of this standard required that a pathname with a trailing <slash> character be treated as if it had a trailing `"/."` everywhere. This specification was ambiguous. In situations where the intent was that the application wanted to require the implementation to accept the

pathname only if it named a directory (existing or to be created as a result of the call performing pathname resolution), literally adding a '.' after the trailing <slash> could be interpreted to require use of that pathname to fail. Some of the uses that created ambiguous requirements included *mkdir*("*newdir*/") and *rmdir*("*existing-dir*/"). POSIX.1-2017 requires that a pathname with a trailing <slash> be rejected unless it refers to a file that is a directory or to a file that is to be created as a directory. The *rename*( ) function and the *mv* utility further specify that a trailing <slash> cannot be used on a pathname naming a file that does not exist when used as the last argument to *rename*( ) or *renameat*( ), or as the last operand to *mv*.

Note that this change does not break any conforming applications; since there were two different types of implementation, no application could have portably depended on either behavior. This change does however require some implementations to be altered to remain compliant. Substantial discussion over a three-year period has shown that the benefits to application developers outweighs the disadvantages for some vendors.

On a historical note, some early applications automatically appended a '/' to every path. Rather than fix the applications, the system implementation was modified to accept this behavior by ignoring any trailing <slash>.

Each directory has exactly one parent directory which is represented by the name **dot-dot** in the first directory. No other directory, regardless of linkages established by symbolic links, is considered the parent directory by POSIX.1-2017.

There are two general categories of interfaces involving pathname resolution: those that follow the symbolic link, and those that do not. There are several exceptions to this rule; for example, *open*(*path*,O_CREAT|O_EXCL) will fail when *path* names a symbolic link. However, in all other situations, the *open*( ) function will follow the link.

What the filename **dot-dot** refers to relative to the root directory is implementation-defined. In Version 7 it refers to the root directory itself; this is the behavior mentioned in POSIX.1-2017. In some networked systems the construction **/../hostname/** is used to refer to the root directory of another host, and POSIX.1 permits this behavior.

Other networked systems use the construct **//hostname** for the same purpose; that is, a double initial <slash> is used. There is a potential problem with existing applications that create full pathnames by taking a trunk and a relative pathname and making them into a single string separated by '/', because they can accidentally create networked pathnames when the trunk is '/'. This practice is not prohibited because such applications can be made to conform by simply changing to use "//" as a separator instead of '/':

> If the trunk is '/', the full pathname will begin with "///" (the initial '/' and the separator "//"). This is the same as '/', which is what is desired. (This is the general case of making a relative pathname into an absolute one by prefixing with "///" instead of '/'.)
>
> If the trunk is "/A", the result is "/A//..."; since non-leading sequences of two or more <slash> characters are treated as a single <slash>, this is equivalent to the desired "/A/...".
>
> If the trunk is "//A", the implementation-defined semantics will apply. (The multiple <slash> rule would apply.)

Application developers should avoid generating pathnames that start with "//". Implementations are strongly encouraged to avoid using this special interpretation since a number of applications currently do not follow this practice and may inadvertently generate "//...".

The term ``root directory'' is only defined in POSIX.1 relative to the process. In some

implementations, there may be no absolute root directory. The initialization of the root directory of a process is implementation-defined.

When the standard says: ``Pathname resolution for a given pathname shall yield the same results when used by any interface in POSIX.1-2017 as long as there are no changes to any files evaluated during pathname resolution for the given pathname between resolutions'', this applies to absolute pathnames or to relative pathnames from the same current working directory. Using the same relative pathname from two different working directories may yield different results.

Earlier versions of this standard were unclear as to whether a pathname was required to be a character string or just a string. This standard is now clear that filenames are just strings, and that pathname processing is locale-independent.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0023 [541,649,825] and XBD/TC2-2008/0024 [825] are applied.

A.4.14 Process ID Reuse

There is no additional rationale provided for this section.

A.4.15 Scheduling Policy

There is no additional rationale provided for this section.

A.4.16 Seconds Since the Epoch

Coordinated Universal Time (UTC) includes leap seconds. However, in POSIX time (seconds since the Epoch), leap seconds are ignored (not applied) to provide an easy and compatible method of computing time differences. Broken-down POSIX time is therefore not necessarily UTC, despite its appearance.

As of December 2007, 23 leap seconds had been added to UTC since the Epoch, 1 January, 1970. Historically, one leap second is added every 15 months on average, so this offset can be expected to grow with time.

Most systems' notion of ``time'' is that of a continuously increasing value, so this value should increase even during leap seconds. However, not only do most systems not keep track of leap seconds, but most systems are probably not synchronized to any standard time reference. Therefore, it is inappropriate to require that a time represented as seconds since the Epoch precisely represent the number of seconds between the referenced time and the Epoch.

It is sufficient to require that applications be allowed to treat this time as if it represented the number of seconds between the referenced time and the Epoch. It is the responsibility of the vendor of the system, and the administrator of the system, to ensure that this value represents the number of seconds between the referenced time and the Epoch as closely as necessary for the application being run on that system.

It is important that the interpretation of time names and seconds since the Epoch values be consistent across conforming systems; that is, it is important that all conforming systems interpret ``536 457 599 seconds since the Epoch'' as 59 seconds, 59 minutes, 23 hours 31 December 1986, regardless of the accuracy of the system's idea of the current time. The expression is given to ensure a consistent interpretation, not to attempt to specify the calendar. The relationship between *tm_yday* and the day of week, day of month, and month is in accordance with the

Gregorian calendar, and so is not specified in POSIX.1.

Consistent interpretation of seconds since the Epoch can be critical to certain types of distributed applications that rely on such timestamps to synchronize events. The accrual of leap seconds in a time standard is not predictable. The number of leap seconds since the Epoch will likely increase. POSIX.1 is more concerned about the synchronization of time between applications of astronomically short duration.

Note that *tm_yday* is zero-based, not one-based, so the day number in the example above is 364. Note also that the division is an integer division (discarding remainder) as in the C language.

Note also that the meaning of *gmtime*( ), *localtime*( ), and *mktime*( ) is specified in terms of this expression. However, the ISO C standard computes *tm_yday* from *tm_mday*, *tm_mon*, and *tm_year* in *mktime*( ). Because it is stated as a (bidirectional) relationship, not a function, and because the conversion between month-day-year and day-of-year dates is presumed well known and is also a relationship, this is not a problem.

Implementations that implement **time_t** as a signed 32-bit integer will overflow in 2 038. This standard requires that **time_t** be an integer type with implementation-defined size, but does not mandate a particular size. The requirement that **time_t** be integral is an additional constraint beyond the ISO C standard, which allows a real-floating **time_t**. Implementation practice has shown that much existing code is unprepared to deal with a floating-point **time_t**, and that use of **struct timespec** is a more uniform way to provide sub-second time manipulation within applications.

See also Epoch (on page 3492).

The topic of whether seconds since the Epoch should account for leap seconds has been debated on a number of occasions, and each time consensus was reached (with acknowledged dissent each time) that the majority of users are best served by treating all days identically. (That is, the majority of applications were judged to assume a single length—as measured in seconds since the Epoch ‡for all days. Thus, leap seconds are not applied to seconds since the Epoch.) Those applications which do care about leap seconds can determine how to handle them in whatever way those applications feel is best. This was particularly emphasized because there was disagreement about what the best way of handling leap seconds might be. It is a practical impossibility to mandate that a conforming implementation must have a fixed relationship to any particular official clock (consider isolated systems, or systems performing ``reruns'' by setting the clock to some arbitrary time).

Note that as a practical consequence of this, the length of a second as measured by some external standard is not specified. This unspecified second is nominally equal to an International System (SI) second in duration. Applications must be matched to a system that provides the particular handling of external time in the way required by the application.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/12 is applied, making an editorial correction to the paragraph commencing ``How any changes to the value of seconds ...''.

A.4.17 Semaphore

There is no additional rationale provided for this section.

A.4.18 Thread-Safety

Where the interface of a function required by POSIX.1-2017 precludes thread-safety, an alternate thread-safe form is provided. The names of these thread-safe forms are the same as the non-thread-safe forms with the addition of the suffix ``_r''. The suffix ``_r'' is historical, where the `'r'` stood for ``reentrant''.

In some cases, thread-safety is provided by restricting the arguments to an existing function.

See also Section B.2.9.1 (on page 3647).

A.4.19 Tracing

Refer to Section B.2.11 (on page 3664).

A.4.20 Treatment of Error Conditions for Mathematical Functions

It is intended that undeserved underflow and inexact floating-point exceptions are raised only if avoiding them would be too costly.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0025 [543] is applied.

A.4.21 Treatment of NaN Arguments for Mathematical Functions

There is no additional rationale provided for this section.

A.4.22 Utility

There is no additional rationale provided for this section.

A.4.23 Variable Assignment

There is no additional rationale provided for this section.

A.5 File Format Notation

The notation for spaces allows some flexibility for application output. Note that an empty character position in *format* represents one or more <blank> characters on the output (not *white space*, which can include <newline> characters). Therefore, another utility that reads that output as its input must be prepared to parse the data using *scanf*( ), *awk*, and so on. The `'Δ'` character is used when exactly one <space> is output.

The treatment of integers and spaces is different from the *printf*( ) function in that they can be surrounded with <blank> characters. This was done so that, given a format such as:

`"%d\n",`*<foo>*

the implementation could use a *printf*( ) call such as:

```
printf("%6d\n", foo);
```

and still conform. This notation is thus somewhat like *scanf*( ) in addition to *printf*( ).

The *printf*() function was chosen as a model because most of the standard developers were familiar with it. One difference from the C function *printf*() is that the `l` and `h` conversion specifier characters are not used. As expressed by the Shell and Utilities volume of POSIX.1-2017, there is no differentiation between decimal values for type **int**, type **long**, or type **short**. The conversion specifications `%d` or `%i` should be interpreted as an arbitrary length sequence of digits. Also, no distinction is made between single precision and double precision numbers (**float** or **double** in C). These are simply referred to as floating-point numbers.

Many of the output descriptions in the Shell and Utilities volume of POSIX.1-2017 use the term ``line'', such as:

```
"%s", <input line>
```

Since the definition of *line* includes the trailing <newline> already, there is no need to include a `'\n'` in the format; a double <newline> would otherwise result.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0026 [584] is applied.

A.6 Character Set

A.6.1 Portable Character Set

The portable character set is listed in full so there is no dependency on the ISO/IEC 646:1991 standard (or historically ASCII) encoded character set, although the set is identical to the characters defined in the International Reference version of the ISO/IEC 646:1991 standard.

POSIX.1-2017 poses no requirement that multiple character sets or codesets be supported, leaving this as a marketing differentiation for implementors. Although multiple charmap files are supported, it is the responsibility of the implementation to provide the file(s); if only one is provided, only that one will be accessible using the *localedef* **–f** option.

The statement about invariance in codesets for the portable character set is worded to avoid precluding implementations where multiple incompatible codesets are available (for instance, ASCII and EBCDIC). The standard utilities cannot be expected to produce predictable results if they access portable characters that vary on the same implementation.

Not all character sets need include the portable character set, but each locale must include it. For example, a Japanese-based locale might be supported by a mixture of character sets: JIS X 0201 Roman (a Japanese version of the ISO/IEC 646:1991 standard), JIS X 0208, and JIS X 0201 Katakana. Not all of these character sets include the portable characters, but at least one does (JIS X 0201 Roman).

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0027 [584,967] and XBD/TC2-2008/0028 [745] are applied.

A.6.2 Character Encoding

Encoding mechanisms based on single shifts, such as the EUC encoding used in some Asian and other countries, can be supported via the current charmap mechanism. With single-shift encoding, each character is preceded by a shift code (SS2 or SS3). A complete EUC code, consisting of the portable character set (G0) and up to three additional character sets (G1, G2, G3), can be described using the current charmap mechanism; the encoding for each character in additional character sets G2 and G3 must then include their single-shift code. Other mechanisms to support locales based on encoding mechanisms such as locking shift are not addressed by this volume of POSIX.1-2017.

The encodings for <slash> and <period> are required to be the same across all locales, in part because pathname resolution requires recognition of these bytes. It is a fortunate accident that all common shift-based encodings did not use either <slash> or <period> as a valid second byte in a multi-byte character.

The encodings for <newline> and <carriage-return> are required to be the same across all locales since they are special to the general terminal interface and cannot be changed (see XBD Section 11.1.9, on page 204).

Earlier versions of this standard did not state the requirement that the POSIX locale contains 256 single-byte characters. This was an oversight; the intention was always that the POSIX locale should have an 8-bit-clean single-byte encoding.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0029 [663,967] and XBD/TC2-2008/0030 [745] are applied.

A.6.3 C Language Wide-Character Codes

The standard does not specify how wide characters are encoded or provide a method for defining wide characters in a charmap. It specifies ways of translating between wide characters and multi-byte characters. The standard does not prevent an extension from providing a method to define wide characters.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/13 is applied, adding a statement that the standard has no means of defining a wide-character codeset.

A.6.4 Character Set Description File

IEEE PASC Interpretation 1003.2 #196 is applied, removing three lines of text dealing with ranges of symbolic names using position constant values which had been erroneously included in the final IEEE P1003.2b draft standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/14 is applied, correcting the example and adding a statement that the standard provides no means of defining a wide-character codeset.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/15 is applied, allowing the value zero for the width value of **WIDTH** and **WIDTH_DEFAULT**. This is required to cover some existing locales.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0031 [967] is applied.

A.6.4.1 State-Dependent Character Encodings

A requirement was considered that would force utilities to eliminate any redundant locking shifts, but this was left as a quality of implementation issue.

This change satisfies the following requirement from the ISO POSIX-2:1993 standard, Annex H.1:

> *The support of state-dependent (shift encoding) character sets should be addressed fully. See descriptions of these in XBD Section 6.2 (on page 128). If such character encodings are supported, it is expected that this will impact XBD Section 6.2 (on page 128), Chapter 7 (on page 135), Chapter 9 (on page 181), and the comm, cut, diff, grep, head, join, paste, and tail utilities.*

The character set description file provides:

> The capability to describe character set attributes (such as collation order or character classes) independent of character set encoding, and using only the characters in the portable character set. This makes it possible to create generic *localedef* source files for all codesets that share the portable character set (such as the ISO 8859 family or IBM Extended ASCII).
>
> Standardized symbolic names for all characters in the portable character set, making it possible to refer to any such character regardless of encoding.

Implementations are free to choose their own symbolic names, as long as the names identified by the Base Definitions volume of POSIX.1-2017 are also defined; this provides support for already existing ``character names''.

The names selected for the members of the portable character set follow the ISO/IEC 8859-1:1998 standard and the ISO/IEC 10646-1:2000 standard. However, several commonly used UNIX system names occur as synonyms in the list:

> The historical UNIX system names are used for control characters.
>
> The word ``slash'' is given in addition to ``solidus''.
>
> The word ``backslash'' is given in addition to ``reverse-solidus''.
>
> The word ``hyphen'' is given in addition to ``hyphen-minus''.
>
> The word ``period'' is given in addition to ``full-stop''.
>
> For digits, the word ``digit'' is eliminated.
>
> For letters, the words ``Latin Capital Letter'' and ``Latin Small Letter'' are eliminated.
>
> The words ``left brace'' and ``right brace'' are given in addition to ``left-curly-bracket'' and ``right-curly-bracket''.
>
> The names of the digits are preferred over the numbers to avoid possible confusion between `'0'` and `'O'`, and between `'1'` and `'l'` (one and the letter ell).

The names for the control characters in XBD Chapter 6 (on page 125) were taken from the ISO/IEC 4873:1991 standard.

The charmap file was introduced to resolve problems with the portability of, especially, *localedef* sources. POSIX.1-2017 assumes that the portable character set is constant across all locales, but does not prohibit implementations from supporting two incompatible codings, such as both ASCII and EBCDIC. Such dual-support implementations should have all charmaps and *localedef* sources encoded using one portable character set, in effect cross-compiling for the other environment. Naturally, charmaps (and *localedef* sources) are only portable without transformation between systems using the same encodings for the portable character set. They

119313 can, however, be transformed between two sets using only a subset of the actual characters (the
119314 portable character set). However, the particular coded character set used for an application or an
119315 implementation does not necessarily imply different characteristics or collation; on the contrary,
119316 these attributes should in many cases be identical, regardless of codeset. The charmap provides
119317 the capability to define a common locale definition for multiple codesets (the same *localedef*
119318 source can be used for codesets with different extended characters; the ability in the charmap to
119319 define empty names allows for characters missing in certain codesets).

119320 The **<escape_char>** declaration was added at the request of the international community to ease
119321 the creation of portable charmap files on terminals not implementing the default
119322 <backslash>-escape. The **<comment_char>** declaration was added at the request of the
119323 international community to eliminate the potential confusion between the <number-sign> and
119324 the hash sign.

119325 The octal number notation with no leading zero required was selected to match those of *awk* and
119326 *tr* and is consistent with that used by *localedef*. To avoid confusion between an octal constant and
119327 the back-references used in *localedef* source, the octal, hexadecimal, and decimal constants must
119328 contain at least two digits. As single-digit constants are relatively rare, this should not impose
119329 any significant hardship. Provision is made for more digits to account for systems in which the
119330 byte size is larger than 8 bits. For example, a Unicode (ISO/IEC 10646-1:2000 standard) system
119331 that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits.

119332 The decimal notation is supported because some newer international standards define character
119333 values in decimal, rather than in the old column/row notation.

119334 The charmap identifies the coded character sets supported by an implementation. At least one
119335 charmap must be provided, but no implementation is required to provide more than one.
119336 Likewise, implementations can allow users to generate new charmaps (for instance, for a new
119337 version of the ISO 8859 family of coded character sets), but does not have to do so. If users are
119338 allowed to create new charmaps, the system documentation describes the rules that apply (for
119339 instance, ``only coded character sets that are supersets of the ISO/IEC 646:1991 standard IRV, no
119340 multi-byte characters'').

119341 This addition of the **WIDTH** specification satisfies the following requirement from the
119342 ISO POSIX-2:1993 standard, Annex H.1:

119343 (9) *The definition of column position relies on the implementation's knowledge of the integral*
119344 *width of the characters. The charmap or LC_CTYPE locale definitions should be enhanced to*
119345 *allow application specification of these widths.*

119346 The character ``width'' information was first considered for inclusion under *LC_CTYPE* but was
119347 moved because it is more closely associated with the information in the charmap than
119348 information in the locale source (cultural conventions information). Concerns were raised that
119349 formalizing this type of information is moving the locale source definition from the codeset-
119350 independent entity that it was designed to be to a repository of codeset-specific information. A
119351 similar issue occurred with the **<code_set_name>**, **<mb_cur_max>**, and **<mb_cur_min>**
119352 information, which was resolved to reside in the charmap definition.

119353 The width definition was added to the IEEE P1003.2b draft standard with the intent that the
119354 *wcswidth*() and/or *wcwidth*() functions (currently specified in the System Interfaces volume of
119355 POSIX.1-2017) be the mechanism to retrieve the character width information.

A.7 Locale

A.7.1 General

The description of locales is based on work performed in the UniForum Technical Committee, Subcommittee on Internationalization. Wherever appropriate, keywords are taken from the ISO C standard or the X/Open Portability Guide.

The value used to specify a locale with environment variables is the name specified as the *name* operand to the *localedef* utility when the locale was created. This provides a verifiable method to create and invoke a locale.

The ``object'' definitions need not be portable, as long as ``source'' definitions are. Strictly speaking, source definitions are portable only between implementations using the same character set(s). Such source definitions, if they use symbolic names only, easily can be ported between systems using different codesets, as long as the characters in the portable character set (see XBD Section 6.1, on page 125) have common values between the codesets; this is frequently the case in historical implementations. Of source, this requires that the symbolic names used for characters outside the portable character set be identical between character sets. The definition of symbolic names for characters is outside the scope of POSIX.1-2017, but is certainly within the scope of other standards organizations.

Applications can select the desired locale by invoking the *setlocale*( ) function (or equivalent) with the appropriate value. If the function is invoked with an empty string, the value of the corresponding environment variable is used. If the environment variable is not set or is set to the empty string, the implementation sets the appropriate environment as defined in XBD Chapter 8 (on page 173).

A.7.2 POSIX Locale

On POSIX.1 implementations the POSIX locale is equal to the C locale, even though the requirements for the POSIX locale are more extensive than the ISO C standard requirements for the C locale. To avoid being classified as a C-language function, the name has been changed to the POSIX locale; the environment variable value can be either `"POSIX"` or, for historical reasons, `"C"`.

The POSIX definitions mirror the historical UNIX system behavior.

The use of symbolic names for characters in the tables does not imply that the POSIX locale must be described using symbolic character names, but merely that it may be advantageous to do so.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0032 [796] and XBD/TC2-2008/0033 [663] are applied.

A.7.3 Locale Definition

The decision to separate the file format from the *localedef* utility description was only partially editorial. Implementations may provide other interfaces than *localedef*. Requirements on ``the utility'', mostly concerning error messages, are described in this way because they are meant to affect the other interfaces implementations may provide as well as *localedef*.

The text about POSIX2_LOCALEDEF does not mean that internationalization is optional; only that the functionality of the *localedef* utility is. REs, for instance, must still be able to recognize, for example, character class expressions such as `"[[:alpha:]]"`. A possible analogy is with an applications development environment; while all conforming implementations must be capable of executing applications, not all need to have the development environment installed. The assumption is that the capability to modify the behavior of utilities (and applications) via locale settings must be supported. If the *localedef* utility is not present, then the only choice is to select an existing (presumably implementation-documented) locale. An implementation could, for example, choose to support only the POSIX locale, which would in effect limit the amount of changes from historical implementations quite drastically. The *localedef* utility is still required, but would always terminate with an exit code indicating that no locale could be created. Supported locales must be documented using the syntax defined in this chapter. (This ensures that users can accurately determine what capabilities are provided. If the implementation decides to provide additional capabilities to the ones in this chapter, that is already provided for.)

If the option is present (that is, locales can be created), then the *localedef* utility must be capable of creating locales based on the syntax and rules defined in this chapter. This does not mean that the implementation cannot also provide alternate means for creating locales.

The octal, decimal, and hexadecimal notations are the same employed by the charmap facility (see XBD Section 6.4, on page 129). To avoid confusion between an octal constant and a back-reference, the octal, hexadecimal, and decimal constants must contain at least two digits. As single-digit constants are relatively rare, this should not impose any significant hardship. Provision is made for more digits to account for systems in which the byte size is larger than 8 bits. For example, a Unicode (see the ISO/IEC 10646-1: 2000 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits. As with the charmap file, multi-byte characters are described in the locale definition file using ``big-endian'' notation for reasons of portability. There is no requirement that the internal representation in the computer memory be in this same order.

One of the guidelines used for the development of this volume of POSIX.1-2017 is that characters outside the invariant part of the ISO/IEC 646: 1991 standard should not be used in portable specifications. The <backslash> character is not in the invariant part; the <number-sign> is, but with multiple representations: as a <number-sign>, and as a hash sign. As far as general usage of these symbols, they are covered by the ``grandfather clause'', but for newly defined interfaces, the WG15 POSIX working group has requested that POSIX provide alternate representations. Consequently, while the default escape character remains the <backslash> and the default comment character is the <number-sign>, implementations are required to recognize alternative representations, identified in the applicable source file via the **<escape_char>** and **<comment_char>** keywords.

A.7.3.1 LC_CTYPE

The *LC_CTYPE* category is primarily used to define the encoding-independent aspects of a character set, such as character classification. In addition, certain encoding-dependent characteristics are also defined for an application via the *LC_CTYPE* category. POSIX.1-2017 does not mandate that the encoding used in the locale is the same as the one used by the application because an implementation may decide that it is advantageous to define locales in a system-wide encoding rather than having multiple, logically identical locales in different encodings, and to convert from the application encoding to the system-wide encoding on usage. Other implementations could require encoding-dependent locales.

In either case, the *LC_CTYPE* attributes that are directly dependent on the encoding, such as **<mb_cur_max>** and the display width of characters, are not user-specifiable in a locale source and are consequently not defined as keywords.

Implementations may define additional keywords or extend the *LC_CTYPE* mechanism to allow application-defined keywords.

The text ``The ellipsis specification shall only be valid within a single encoded character set'' is present because it is possible to have a locale supported by multiple character encodings, as explained in the rationale for XBD Section 6.1 (on page 125). An example given there is of a possible Japanese-based locale supported by a mixture of the character sets JIS X 0201 Roman, JIS X 0208, and JIS X 0201 Katakana. Attempting to express a range of characters across these sets is not logical and the implementation is free to reject such attempts.

As the *LC_CTYPE* character classes are based on the ISO C standard character class definition, the category does not support multi-character elements. For instance, the German character <sharp-s> is traditionally classified as a lowercase letter. There is no corresponding uppercase letter; in proper capitalization of German text, the <sharp-s> will be replaced by `"SS"`; that is, by two characters. This kind of conversion is outside the scope of the **toupper** and **tolower** keywords.

Where POSIX.1-2017 specifies that only certain characters can be specified, as for the keywords **digit** and **xdigit**, the specified characters must be from the portable character set, as shown. As an example, only the Arabic digits 0 through 9 are acceptable as digits.

The character classes **digit**, **xdigit**, **lower**, **upper**, and **space** have a set of automatically included characters. These only need to be specified if the character values (that is, encoding) differs from the implementation default values. It is not possible to define a locale without these automatically included characters unless some implementation extension is used to prevent their inclusion. Such a definition would not be a proper superset of the C locale, and thus, it might not be possible for the standard utilities to be implemented as programs conforming to the ISO C standard.

The definition of character class **digit** requires that only ten characters ‡the ones defining digits ‡ćan be specified; alternate digits (for example, Hindi or Kanji) cannot be specified here. However, the encoding may vary if an implementation supports more than one encoding.

The definition of character class **xdigit** requires that the characters included in character class **digit** are included here also and allows for different symbols for the hexadecimal digits 10 through 15.

The inclusion of the **charclass** keyword satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

(3) *The LC_CTYPE (2.5.2.1) locale definition should be enhanced to allow user-specified additional character classes, similar in concept to the ISO C standard Multibyte Support Extension (MSE) iswctype( ) function.*

This keyword was previously included in The Open Group specifications and is now mandated in the Shell and Utilities volume of POSIX.1-2017.

The symbolic constant {CHARCLASS_NAME_MAX} was also adopted from The Open Group specifications. Applications portability is enhanced by the use of symbolic constants.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0033 [663], XBD/TC2-2008/0034 [663], XBD/TC2-2008/0035 [584], and XBD/TC2-2008/0036 [584] are applied.

A.7.3.2 LC_COLLATE

The rules governing collation depend to some extent on the use. At least five different levels of increasingly complex collation rules can be distinguished:

1. *Byte/machine code order*: This is the historical collation order in the UNIX system and many proprietary operating systems. Collation is here performed character by character, without any regard to context. The primary virtue is that it usually is quite fast and also completely deterministic; it works well when the native machine collation sequence matches the user expectations.

2. *Character order*: On this level, collation is also performed character by character, without regard to context. The order between characters is, however, not determined by the code values, but on the expectations by the user of the ``correct'' order between characters. In addition, such a (simple) collation order can specify that certain characters collate equally (for example, uppercase and lowercase letters).

3. *String ordering*: On this level, entire strings are compared based on relatively straightforward rules. Several ``passes'' may be required to determine the order between two strings. Characters may be ignored in some passes, but not in others; the strings may be compared in different directions; and simple string substitutions may be performed before strings are compared. This level is best described as ``dictionary'' ordering; it is based on the spelling, not the pronunciation, or meaning, of the words.

4. *Text search ordering*: This is a further refinement of the previous level, best described as ``telephone book ordering''; some common homonyms (words spelled differently but with the same pronunciation) are collated together; numbers are collated as if they were spelled out, and so on.

5. *Semantic-level ordering*: Words and strings are collated based on their meaning; entire words (such as ``the'') are eliminated; the ordering is not deterministic. This usually requires special software and is highly dependent on the intended use.

While the historical collation order formally is at level 1, for the English language it corresponds roughly to elements at level 2. The user expects to see the output from the *ls* utility sorted very much as it would be in a dictionary. While telephone book ordering would be an optimal goal for standard collation, this was ruled out as the order would be language-dependent. Furthermore, a requirement was that the order must be determined solely from the text string and the collation rules; no external information (for example, ``pronunciation dictionaries'') could be required.

As a result, the goal for the collation support is at level 3. This also matches the requirements for the Canadian collation order, as well as other, known collation requirements for alphabetic scripts. It specifically rules out collation based on pronunciation rules or based on semantic analysis of the text.

The syntax for the *LC_COLLATE* category source meets the requirements for level 3 and has been verified to produce the correct result with examples based on French, Canadian, and Danish collation order. Because it supports multi-character collating elements, it is also capable

of supporting collation in codesets where a character is expressed using non-spacing characters followed by the base character (such as the ISO/IEC 6937: 2001 standard).

The directives that can be specified in an operand to the **order_start** keyword are based on the requirements specified in several proposed standards and in customary use. The following is a rephrasing of rules defined for ``lexical ordering in English and French'' by the Canadian Standards Association (the text in square brackets is rephrased):

> Once special characters [punctuation] have been removed from original strings, the ordering is determined by scanning forwards (left to right) [disregarding case and diacriticals].
>
> In case of equivalence, special characters are once again removed from original strings and the ordering is determined by scanning backwards (starting from the rightmost character of the string and back), character by character [disregarding case but considering diacriticals].
>
> In case of repeated equivalence, special characters are removed again from original strings and the ordering is determined by scanning forwards, character by character [considering both case and diacriticals].
>
> If there is still an ordering equivalence after the first three rules have been applied, then only special characters and the position they occupy in the string are considered to determine ordering. The string that has a special character in the lowest position comes first. If two strings have a special character in the same position, the character [with the lowest collation value] comes first. In case of equality, the other special characters are considered until there is a difference or until all special characters have been exhausted.

It is estimated that this part of POSIX.1-2017 covers the requirements for all European languages, and no particular problems are anticipated with Slavic or Middle East character sets.

The Far East (particularly Japanese/Chinese) collations are often based on contextual information and pronunciation rules (the same ideogram can have different meanings and different pronunciations). Such collation, in general, falls outside the desired goal of POSIX.1-2017. There are, however, several other collation rules (stroke/radical or ``most common pronunciation'') that can be supported with the mechanism described here.

The character order is defined by the order in which characters and elements are specified between the **order_start** and **order_end** keywords. Weights assigned to the characters and elements define the collation sequence; in the absence of weights, the character order is also the collation sequence.

The **position** keyword provides the capability to consider, in a compare, the relative position of characters not subject to **IGNORE**. As an example, consider the two strings `"o-ring"` and `"or-ing"`. Assuming the <hyphen-minus> is subject to **IGNORE** on the first pass, the two strings compare equal, and the position of the <hyphen-minus> is immaterial. On second pass, all characters except the <hyphen-minus> are subject to **IGNORE**, and in the normal case the two strings would again compare equal. By taking position into account, the first collates before the second.

This standard recommends (by the use of ``should'' in the normative text) that all implementation-provided locales define a collation sequence that has a total ordering of all characters unless the locale name has an `'@'` modifier indicating that it has a special collation sequence. Defining locales in this way eliminates unexpected behavior when non-identical strings can collate equally (for example, `sort -u` and `sort | uniq` are not equivalent). The exception for locales with a suitable `'@'` modifier in the name allows implementations to supply locales which do not have a total ordering of all characters provided that they draw attention to it in the modifier name. For example, `@icase` could indicate that each upper and lowercase

119573 character pair collates equally. Even with an '@' modifier, total ordering is preferred when
119574 possible; for example, characters that are ``ignored'' in dictionary order need not be completely
119575 ignored (by using **IGNORE** for all collation weights), but can instead be given a unique weight
119576 after one or more **IGNORE** weights.

119577 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0037 [938], XBD/TC2-2008/0038 [663],
119578 and XBD/TC2-2008/0039 [584] are applied.

119579 *A.7.3.3 LC_MONETARY*

119580 The currency symbol does not appear in *LC_MONETARY* because it is not defined in the C
119581 locale of the ISO C standard.

119582 The ISO C standard limits the size of decimal points and thousands delimiters to single-byte
119583 values. In locales based on multi-byte coded character sets, this cannot be enforced;
119584 POSIX.1-2017 does not prohibit such characters, but makes the behavior unspecified (in the text
119585 ``In contexts where other standards ...'').

119586 The grouping specification is based on, but not identical to, the ISO C standard. The –1 indicates
119587 that no further grouping is performed; the equivalent of {CHAR_MAX} in the ISO C standard.

119588 The text ``the value is not available in the locale'' is taken from the ISO C standard and is used
119589 instead of the ``unspecified'' text in early proposals. There is no implication that omitting these
119590 keywords or assigning them values of "" or –1 produces unspecified results; such omissions or
119591 assignments eliminate the effects described for the keyword or produce zero-length strings, as
119592 appropriate.

119593 The locale definition is an extension of the ISO C standard *localeconv*() specification. In
119594 particular, rules on how **currency_symbol** is treated are extended to also cover **int_curr_symbol**,
119595 and **p_set_by_space** and **n_sep_by_space** have been augmented with the value 2, which places
119596 a <space> between the sign and the symbol. This has been updated to match the
119597 ISO/IEC 9899:1999 standard requirements and is an incompatible change from UNIX 98 and the
119598 ISO POSIX-2 standard and the ISO POSIX-1:1996 standard requirements. The following table
119599 shows the result of various combinations:

119600 | | | **p_sep_by_space** | | |
119601 | | | **2** | **1** | **0** |
119602 | **p_cs_precedes** = 1 | **p_sign_posn** = 0 | ($1.25) | ($ 1.25) | ($1.25) |
119603 | | **p_sign_posn** = 1 | + $1.25 | +$ 1.25 | +$1.25 |
119604 | | **p_sign_posn** = 2 | $1.25 + | $ 1.25+ | $1.25+ |
119605 | | **p_sign_posn** = 3 | + $1.25 | +$ 1.25 | +$1.25 |
119606 | | **p_sign_posn** = 4 | $ +1.25 | $+ 1.25 | $+1.25 |
119607 | **p_cs_precedes** = 0 | **p_sign_posn** = 0 | (1.25 $) | (1.25 $) | (1.25$) |
119608 | | **p_sign_posn** = 1 | +1.25 $ | +1.25 $ | +1.25$ |
119609 | | **p_sign_posn** = 2 | 1.25$ + | 1.25 $+ | 1.25$+ |
119610 | | **p_sign_posn** = 3 | 1.25+ $ | 1.25 +$ | 1.25+$ |
119611 | | **p_sign_posn** = 4 | 1.25$ + | 1.25 $+ | 1.25$+ |

119612 The following is an example of the interpretation of the **mon_grouping** keyword. Assuming that
119613 the value to be formatted is 123 456 789 and the **mon_thousands_sep** is <apostrophe>, then the
119614 following table shows the result. The third column shows the equivalent string in the ISO C
119615 standard that would be used by the *localeconv*() function to accommodate this grouping.

mon_grouping	Formatted Value	ISO C String
3;–1	123456'789	"\3\177"
3	123'456'789	"\3"
3;2;–1	1234'56'789	"\3\2\177"
3;2	12'34'56'789	"\3\2"
–1	123456789	"\177"

In these examples, the octal value of {CHAR_MAX} is 177.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/6 adds a correction that permits the Euro currency symbol and addresses extensibility. The correction is stated using the term ``should'' intentionally, in order to make this a recommendation rather than a restriction on implementations. This allows for flexibility in implementations on how they handle future currency symbol additions.

IEEE Std 1003.1-2001/Cor 1-2002, tem XBD/TC1/D6/5 is applied, adding the **int_[np]_*** values to the POSIX locale definition of *LC_MONETARY*.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/16 is applied, updating the descriptions of **p_sep_by_space**, **n_sep_by_space**, **int_p_sep_by_space**, and **int_n_sep_by_space** to match the description of these keywords in the ISO C standard and the System Interfaces volume of POSIX.1-2017, *localeconv*( ).

A.7.3.4 *LC_NUMERIC*

See the rationale for *LC_MONETARY* for a description of the behavior of grouping.

A.7.3.5 *LC_TIME*

Although certain of the conversion specifications in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these conversion specifications may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The *LC_TIME* descriptions of **abday**, **day**, **mon**, and **abmon** imply a Gregorian style calendar (7-day weeks, 12-month years, leap years, and so on). Formatting time strings for other types of calendars is outside the scope of POSIX.1-2017.

While the ISO 8601:2004 standard numbers the weekdays starting with Monday, historical practice is to use the Sunday as the first day. Rather than change the order and introduce potential confusion, the days must be specified beginning with Sunday; previous references to ``first day'' have been removed. Note also that the Shell and Utilities volume of POSIX.1-2017 *date* utility supports numbering compliant with the ISO 8601:2004 standard.

As specified under *date* in the Shell and Utilities volume of POSIX.1-2017 and *strftime*( ) in the System Interfaces volume of POSIX.1-2017, the conversion specifications corresponding to the optional keywords consist of a modifier followed by a traditional conversion specification (for instance, `%Ex`). If the optional keywords are not supported by the implementation or are unspecified for the current locale, these modified conversion specifications are treated as the traditional conversion specifications. For example, assume the following keywords:

```
alt_digits   "0th";"1st";"2nd";"3rd";"4th";"5th";\
             "6th";"7th";"8th";"9th";"10th"
d_fmt        "The %Od day of %B in %Y"
```

On July 4th 1776, the `%x` conversion specifications would result in "`The 4th day of July`

119659 in 1776", while on July 14th 1789 it would result in "The 14 day of July in 1789". It
119660 can be noted that the above example is for illustrative purposes only; the %O modifier is
119661 primarily intended to provide for Kanji or Hindi digits in *date* formats.

119662 The following is an example for Japan that supports the current plus last three Emperors and
119663 reverts to Western style numbering for years prior to the Meiji era. The example also allows for
119664 the custom of using a special name for the first year of an era instead of using 1. (The examples
119665 substitute romaji where kanji should be used.)

```
119666 era_d_fmt "%EY%mgatsu%dnichi (%a)"

119667 era     "+:2:1990/01/01:+*:Heisei:%EC%Eynen";\
119668         "+:1:1989/01/08:1989/12/31:Heisei:%ECgannen";\
119669         "+:2:1927/01/01:1989/01/07:Shouwa:%EC%Eynen";\
119670         "+:1:1926/12/25:1926/12/31:Shouwa:%ECgannen";\
119671         "+:2:1913/01/01:1926/12/24:Taishou:%EC%Eynen";\
119672         "+:1:1912/07/30:1912/12/31:Taishou:%ECgannen";\
119673         "+:2:1869/01/01:1912/07/29:Meiji:%EC%Eynen";\
119674         "+:1:1868/09/08:1868/12/31:Meiji:%ECgannen";\
119675         "-:1868:1868/09/07:-*::%Ey"
```

119676 Assuming that the current date is September 21, 1991, a request to *date* or *strftime*() would yield
119677 the following results:

```
119678 %Ec - Heisei3nen9gatsu21nichi (Sat) 14:39:26
119679 %EC - Heisei
119680 %Ex - Heisei3nen9gatsu21nichi (Sat)
119681 %Ey - 3
119682 %EY - Heisei3nen
```

119683 Example era definitions for the Republic of China:

```
119684 era     "+:2:1913/01/01:+*:ChungHwaMingGuo:%EC%EyNen";\
119685         "+:1:1912/1/1:1912/12/31:ChungHwaMingGuo:%ECYuenNen";\
119686         "+:1:1911/12/31:-*:MingChien:%EC%EyNen"
```

119687 Example definitions for the Christian Era:

```
119688 era     "+:1:0001/01/01:+*:AD:%EC %Ey";\
119689         "+:1:-0001/12/31:-*:BC:%Ey %EC"
```

119690 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0040 [912] is applied.

119691 *A.7.3.6 LC_MESSAGES*

119692 The **yesstr** and **nostr** locale keywords and the YESSTR and NOSTR *langinfo* items were formerly
119693 used to match user affirmative and negative responses. In POSIX.1-2017, the **yesexpr**, **noexpr**,
119694 YESEXPR, and NOEXPR extended regular expressions have replaced them. Applications
119695 should use the general locale-based messaging facilities to issue prompting messages which
119696 include sample desired responses.

119697 Affirmative responses like:

```
119698 y
119699 Yes
119700 Yes!
```

119701 and negative responses like:

```
119702 N
```

```
No
Never
No way!
```

should all be recognized as affirmative and negative responses, respectively, by the EREs identified by the **yesexpr** and **noexpr** keywords for English language-based locales. There is no requirement that multi-line responses nor ambiguous responses like:

```
no or yes
yes or no
maybe
```

be correctly classified by either of these EREs. Application writers are encouraged to include locale-specific suggestions for affirmative and negative responses in prompts.

A.7.4 Locale Definition Grammar

There is no additional rationale provided for this section.

A.7.4.1 Locale Lexical Conventions

There is no additional rationale provided for this section.

A.7.4.2 Locale Grammar

There is no additional rationale provided for this section.

A.7.5 Locale Definition Example

The following is an example of a locale definition file that could be used as input to the *localedef* utility. It assumes that the utility is executed with the **−f** option, naming a charmap file with (at least) the following content:

```
CHARMAP
<space>      \x20
<dollar>     \x24
<A>          \101
<a>          \141
<A-acute>    \346
<a-acute>    \365
<A-grave>    \300
<a-grave>    \366
<b>          \142
<C>          \103
<c>          \143
<c-cedilla>  \347
<d>          \x64
<H>          \110
<h>          \150
<eszet>      \xb7
<s>          \x73
<z>          \x7a
END CHARMAP
```

It should not be taken as complete or to represent any actual locale, but only to illustrate the syntax.

```
#
LC_CTYPE
lower   <a>;<b>;<c>;<c-cedilla>;<d>;...;<z>
upper   A;B;C;Ç;...;Z
space   \x20;\x09;\x0a;\x0b;\x0c;\x0d
blank   \040;\011
toupper (<a>,<A>);(b,B);(c,C);(ç,Ç);(d,D);(z,Z)
END LC_CTYPE
#
LC_COLLATE
#
# The following example of collation is based on
# Canadian standard Z243.4.1-1998, "Canadian Alphanumeric
# Ordering Standard for Character Sets of CSA Z234.4 Standard".
# (Other parts of this example locale definition file do not
# purport to relate to Canada, or to any other real culture.)
# The proposed standard defines a 4-weight collation, such that
# in the first pass, characters are compared without regard to
# case or accents; in the second pass, backwards-compare without
# regard to case; in the third pass, forwards-compare without
# regard to diacriticals. In the 3 first passes, non-alphabetic
# characters are ignored; in the fourth pass, only special
# characters are considered, such that "The string that has a
# special character in the lowest position comes first. If two
# strings have a special character in the same position, the
# collation value of the special character determines ordering.
#
# Only a subset of the character set is used here; mostly to
# illustrate the set-up.
#
collating-symbol <NULL>
collating-symbol <LOW_VALUE>
collating-symbol <LOWER-CASE>
collating-symbol <SUBSCRIPT-LOWER>
collating-symbol <SUPERSCRIPT-LOWER>
collating-symbol <UPPER-CASE>
collating-symbol <NO-ACCENT>
collating-symbol <PECULIAR>
collating-symbol <LIGATURE>
collating-symbol <ACUTE>
collating-symbol <GRAVE>
# Further collating-symbols follow.
#
# Properly, the standard does not include any multi-character
# collating elements; the one below is added for completeness.
#
collating_element <ch> from "<c><h>"
collating_element <CH> from "<C><H>"
collating_element <Ch> from "<C><h>"
#
```

```
119796        order_start forward;backward;forward;forward,position
119797        #
119798        # Collating symbols are specified first in the sequence to allocate
119799        # basic collation values to them, lower than that of any character.
119800        <NULL>
119801        <LOW_VALUE>
119802        <LOWER-CASE>
119803        <SUBSCRIPT-LOWER>
119804        <SUPERSCRIPT-LOWER>
119805        <UPPER-CASE>
119806        <NO-ACCENT>
119807        <PECULIAR>
119808        <LIGATURE>
119809        <ACUTE>
119810        <GRAVE>
119811        <RING-ABOVE>
119812        <DIAERESIS>
119813        <TILDE>
119814        # Further collating symbols are given a basic collating value here.
119815        #
119816        # Here follow special characters.
119817        <space>        IGNORE;IGNORE;IGNORE;<space>
119818        # Other special characters follow here.
119819        #
119820        # Here follow the regular characters.
119821        <a>         <a>;<NO-ACCENT>;<LOWER-CASE>;IGNORE
119822        <A>         <a>;<NO-ACCENT>;<UPPER-CASE>;IGNORE
119823        <a-acute>   <a>;<ACUTE>;<LOWER-CASE>;IGNORE
119824        <A-acute>   <a>;<ACUTE>;<UPPER-CASE>;IGNORE
119825        <a-grave>   <a>;<GRAVE>;<LOWER-CASE>;IGNORE
119826        <A-grave>   <a>;<GRAVE>;<UPPER-CASE>;IGNORE
119827        <ae>       "<a><e>";"<LIGATURE><LIGATURE>";\
119828                   "<LOWER-CASE><LOWER-CASE>";IGNORE
119829        <AE>       "<a><e>";"<LIGATURE><LIGATURE>";\
119830                   "<UPPER-CASE><UPPER-CASE>";IGNORE
119831        <b>         <b>;<NO-ACCENT>;<LOWER-CASE>;IGNORE
119832        <B>         <b>;<NO-ACCENT>;<UPPER-CASE>;IGNORE
119833        <c>         <c>;<NO-ACCENT>;<LOWER-CASE>;IGNORE
119834        <C>         <c>;<NO-ACCENT>;<UPPER-CASE>;IGNORE
119835        <ch>        <ch>;<NO-ACCENT>;<LOWER-CASE>;IGNORE
119836        <Ch>        <ch>;<NO-ACCENT>;<PECULIAR>;IGNORE
119837        <CH>        <ch>;<NO-ACCENT>;<UPPER-CASE>;IGNORE
119838        #
119839        # As an example, the strings "Bach" and "bach" could be encoded (for
119840        # compare purposes) as:
119841        # "Bach"  <b>;<a>;<ch>;<LOW_VALUE>;<NO_ACCENT>;<NO_ACCENT>;\
119842        #         <NO_ACCENT>;<LOW_VALUE>;<UPPER-CASE>;<LOWER-CASE>;\
119843        #         <LOWER-CASE>;<NULL>
119844        # "bach"  <b>;<a>;<ch>;<LOW_VALUE>;<NO_ACCENT>;<NO_ACCENT>;\
119845        #         <NO_ACCENT>;<LOW_VALUE>;<LOWER-CASE>;<LOWER-CASE>;\

A.8 Environment Variables

A.8.1 Environment Variable Definition

The variable *environ* is not intended to be declared in any header, but rather to be declared by the user for accessing the array of strings that is the environment. This is the traditional usage of the symbol. Putting it into a header could break some programs that use the symbol for their own purposes.

The decision to restrict conforming systems to the use of digits, uppercase letters, and underscores for environment variable names allows applications to use lowercase letters in their environment variable names without conflicting with any conforming system.

In addition to the obvious conflict with the shell syntax for positional parameter substitution, some historical applications (including some shells) exclude names with leading digits from the environment.

A.8.2 Internationalization Variables

Utilities conforming to the Shell and Utilities volume of POSIX.1-2017 and written in standard C can access the locale variables by issuing the following call:

```
setlocale(LC_ALL, "")
```

If this were omitted, the ISO C standard specifies that the C (or POSIX) locale would be used.

The DESCRIPTION of *setlocale*( ) requires that when setting all categories of a locale, if the value of any of the environment variable searches yields a locale that is not supported (and non-null), the *setlocale*( ) function returns a null pointer and the global locale is unchanged.

For the standard utilities, if any of the environment variables are invalid, it makes sense to default to an implementation-defined, consistent locale environment. It is more confusing for a user to have partial settings occur in case of a mistake. All utilities would then behave in one language/cultural environment. Furthermore, it provides a way of forcing the whole environment to be the implementation-defined default. Disastrous results could occur if a pipeline of utilities partially uses the environment variables in different ways. In this case, it would be appropriate for utilities that use *LANG* and related variables to exit with an error if any of the variables are invalid. For example, users typing individual commands at a terminal might want *date* to work if *LC_MONETARY* is invalid as long as *LC_TIME* is valid. Since these are conflicting reasonable alternatives, POSIX.1-2017 leaves the results unspecified if the locale environment variables would not produce a complete locale matching the specification of the user.

The locale settings of individual categories cannot be truly independent and still guarantee correct results. For example, when collating two strings, characters must first be extracted from each string (governed by *LC_CTYPE*) before being mapped to collating elements (governed by *LC_COLLATE*) for comparison. That is, if *LC_CTYPE* is causing parsing according to the rules of a large, multi-byte code set (potentially returning 20 000 or more distinct character codeset values), but *LC_COLLATE* is set to handle only an 8-bit codeset with 256 distinct characters, meaningful results are obviously impossible.

The *LC_MESSAGES* variable affects the language of messages generated by the standard utilities.

The description of the environment variable names starting with the characters ``LC_'' acknowledges the fact that the interfaces presented may be extended as new international functionality is required. In the ISO C standard, names preceded by ``LC_'' are reserved in the name space for future categories.

To avoid name clashes, new categories and environment variables are divided into two classifications: ``implementation-independent'' and ``implementation-defined''.

Implementation-independent names will have the following format:

`LC_`*`NAME`*

where *NAME* is the name of the new category and environment variable. Capital letters must be used for implementation-independent names.

Implementation-defined names must be in lowercase letters, as below:

`LC_`*`name`*

A.8.3 Other Environment Variables

COLUMNS, LINES

The default values for the number of column positions, *COLUMNS*, and screen height, *LINES*, are unspecified because historical implementations use different methods to determine values corresponding to the size of the screen in which the utility is run. This size is typically known to the implementation through the value of *TERM*, or by more elaborate methods such as extensions to the *stty* utility or knowledge of how the user is dynamically resizing windows on a bit-mapped display terminal. Users should not need to set these variables in the environment unless there is a specific reason to override the default behavior of the implementation, such as to display data in an area arbitrarily smaller than the terminal or window. Values for these variables that are not decimal integers greater than zero are implicitly undefined values; it is unnecessary to enumerate all of the possible values outside of the acceptable set.

LOGNAME

In most implementations, the value of such a variable is easily forged, so security-critical applications should rely on other means of determining user identity. *LOGNAME* is required to be constructed from the portable filename character set for reasons of interchange. No diagnostic condition is specified for violating this rule, and no requirement for enforcement exists. The intent of the requirement is that if extended characters are used, the ``guarantee'' of portability implied by a standard is void.

PATH

Many historical implementations of the Bourne shell do not interpret a trailing <colon> to represent the current working directory and are thus non-conforming. The C Shell and the KornShell conform to POSIX.1-2017 on this point. The usual name of dot may also be used to refer to the current working directory.

Many implementations historically have used a default value of **/bin** and **/usr/bin** for the *PATH* variable. POSIX.1-2017 does not mandate this default path be identical to that retrieved from *getconf PATH* because it is likely that the standardized utilities may be provided in another directory separate from the directories used by some historical applications.

SHELL

The *SHELL* variable names the preferred shell of the user; it is a guide to applications. There is no direct requirement that that shell conform to POSIX.1-2017; that decision should rest with the user. It is the intention of the standard developers that alternative shells be permitted, if the user chooses to develop or acquire one. An operating system that builds its shell into the ``kernel'' in such a manner that alternative shells would be impossible does not conform to the spirit of POSIX.1-2017.

TZ

The quoted form of the timezone variable allows timezone names of the form UTC+1 (or any name that contains the <plus-sign> ('+'), the <hyphen-minus> ('−'), or digits), which may be appropriate for countries that do not have an official timezone name. It would be coded as <UTC+1>+1<UTC+2>, which would cause *std* to have a value of UTC+1 and *dst* a value of UTC+2, each with a length of 5 characters. This does not appear to conflict with any existing usage. The characters '<' and '>' were chosen for quoting because they are easier to parse visually than a quoting character that does not provide some sense of bracketing (and in a string like this, such bracketing is helpful). They were also chosen because they do not need special treatment when assigning to the *TZ* variable. Users are often confused by embedding quotes in a string. Because '<' and '>' are meaningful to the shell, the whole string would have to be quoted, but that is easily explained. (Parentheses would have presented the same problems.) Although the '>' symbol could have been permitted in the string by either escaping it or doubling it, it seemed of little value to require that. This could be provided as an extension if there was a need. Timezone names of this new form lead to a requirement that the value of {_POSIX_TZNAME_MAX} change from 3 to 6.

Since the *TZ* environment variable is usually inherited by all applications started by a user after the value of the *TZ* environment variable is changed and since many applications run using the C or POSIX locale, using characters that are not in the portable character set in the *std* and *dst* fields could cause unexpected results.

The format of the *TZ* environment variable is changed in Issue 6 to allow for the quoted form, as defined in earlier versions of the ISO POSIX-1 standard.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/7 is applied, adding the *ctime_r*() and *localtime_r*() functions to the list of functions that use the *TZ* environment variable.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0041 [584] is applied.

A.9 Regular Expressions

Rather than repeating the description of REs for each utility supporting REs, the standard developers preferred a common, comprehensive description of regular expressions in one place. The most common behavior is described here, and exceptions or extensions to this are documented for the respective utilities, as appropriate.

The BRE corresponds to the *ed* or historical *grep* type, and the ERE corresponds to the historical *egrep* type (now *grep* **−E**).

The text is based on the *ed* description and substantially modified, primarily to aid developers and others in the understanding of the capabilities and limitations of REs. Much of this was influenced by internationalization requirements.

It should be noted that the definitions in this section do not cover the *tr* utility; the *tr* syntax does not employ REs.

The specification of REs is particularly important to internationalization because pattern matching operations are very basic operations in business and other operations. The syntax and rules of REs are intended to be as intuitive as possible to make them easy to understand and use. The historical rules and behavior do not provide that capability to non-English language users, and do not provide the necessary support for commonly used characters and language constructs. It was necessary to provide extensions to the historical RE syntax and rules to accommodate other languages.

As they are limited to bracket expressions, the rationale for these modifications is in XBD Section 9.3.5 (on page 184).

A.9.1 Regular Expression Definitions

It is possible to determine what strings correspond to subexpressions by recursively applying the leftmost longest rule to each subexpression, but only with the proviso that the overall match is leftmost longest. For example, matching `"\(ac*\)c*d[ac]*\1"` against *acdacaaa* matches *acdacaaa* (with \1=*a*); simply matching the longest match for `"\(ac*\)"` would yield \1=*ac*, but the overall match would be smaller (*acdac*). Conceptually, the implementation must examine every possible match and among those that yield the leftmost longest total matches, pick the one that does the longest match for the leftmost subexpression, and so on. Note that this means that matching by subexpressions is context-dependent: a subexpression within a larger RE may match a different string from the one it would match as an independent RE, and two instances of the same subexpression within the same larger RE may match different lengths even in similar sequences of characters. For example, in the ERE `"(a.*b)(a.*b)"`, the two identical subexpressions would match four and six characters, respectively, of *accbaccccb*.

The definition of single character has been expanded to include also collating elements consisting of two or more characters; this expansion is applicable only when a bracket expression is included in the BRE or ERE. An example of such a collating element may be the Dutch *ij*, which collates as a `'y'`. In some encodings, a ligature ``i with j'' exists as a character and would represent a single-character collating element. In another encoding, no such ligature exists, and the two-character sequence *ij* is defined as a multi-character collating element. Outside brackets, the *ij* is treated as a two-character RE and matches the same characters in a string. Historically, a bracket expression only matched a single character. The ISO POSIX-2: 1993 standard required bracket expressions like `"[^[:lower:]]"` to match multi-character collating elements such as `"ij"`. However, this requirement led to behavior that many users did not expect and that could not feasibly be mimicked in user code, and it was rarely if ever implemented correctly. The current standard leaves it unspecified whether a bracket expression matches a multi-character collating element, allowing both historical and ISO POSIX-2: 1993 standard implementations to conform.

Also, in the current standard, it is unspecified whether character class expressions like `"[:lower:]"` can include multi-character collating elements like `"ij"`; hence `"[[:lower:]]"` can match `"ij"`, and `"[^[:lower:]]"` can fail to match `"ij"`. Common practice is for a character class expression to match a collating element if it matches the collating element's first character.

A.9.2 Regular Expression General Requirements

The definition of which sequence is matched when several are possible is based on the leftmost-longest rule historically used by deterministic recognizers. This rule is easier to define and describe, and arguably more useful, than the first-match rule historically used by non-deterministic recognizers. It is thought that dependencies on the choice of rule are rare; carefully contrived examples are needed to demonstrate the difference.

A formal expression of the leftmost-longest rule is:

> The search is performed as if all possible suffixes of the string were tested for a prefix matching the pattern; the longest suffix containing a matching prefix is chosen, and the longest possible matching prefix of the chosen suffix is identified as the matching sequence.

Historically, most RE implementations only match lines, not strings. However, that is more an effect of the usage than of an inherent feature of REs themselves. Consequently, POSIX.1-2017 does not regard <newline> characters as special; they are ordinary characters, and both a <period> and a non-matching list can match them. Those utilities (like *grep*) that do not allow <newline> characters to match are responsible for eliminating any <newline> from strings before matching against the RE. The *regcomp*( ) function, however, can provide support for such processing without violating the rules of this section.

Some implementations of *egrep* have had very limited flexibility in handling complex EREs. POSIX.1-2017 does not attempt to define the complexity of a BRE or ERE, but does place a lower limit on it—any RE must be handled, as long as it can be expressed in 256 bytes or less. (Of course, this does not place an upper limit on the implementation.) There are historical programs using a non-deterministic-recognizer implementation that should have no difficulty with this limit. It is possible that a good approach would be to attempt to use the faster, but more limited, deterministic recognizer for simple expressions and to fall back on the non-deterministic recognizer for those expressions requiring it. Non-deterministic implementations must be careful to observe the rules on which match is chosen; the longest match, not the first match, starting at a given character is used.

The term ``invalid'' highlights a difference between this section and some others: POSIX.1-2017 frequently avoids mandating of errors for syntax violations because they can be used by implementors to trigger extensions. However, the authors of the internationalization features of REs wanted to mandate errors for certain conditions to identify usage problems or non-portable constructs. These are identified within this rationale as appropriate. The remaining syntax violations have been left implicitly or explicitly undefined. For example, the BRE construct `"\{1,2,3\}"` does not comply with the grammar. A conforming application cannot rely on it producing an error nor matching the literal characters `"\{1,2,3\}"`.

The term ``undefined'' was used in favor of ``unspecified'' because many of the situations are considered errors on some implementations, and the standard developers considered that consistency throughout the section was preferable to mixing undefined and unspecified.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0042 [554] is applied.

A.9.3 Basic Regular Expressions

There is no additional rationale provided for this section.

A.9.3.1 BREs Matching a Single Character or Collating Element

There is no additional rationale provided for this section.

A.9.3.2 BRE Ordinary Characters

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0043 [554] is applied.

A.9.3.3 BRE Special Characters

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0043 [554] is applied.

A.9.3.4 Periods in BREs

There is no additional rationale provided for this section.

A.9.3.5 RE Bracket Expression

Range expressions are, historically, an integral part of REs. However, the requirements of ``natural language behavior'' and portability do conflict. In the POSIX locale, ranges must be treated according to the collating sequence and include such characters that fall within the range based on that collating sequence, regardless of character values. In other locales, ranges have unspecified behavior.

Some historical implementations allow range expressions where the ending range point of one range is also the starting point of the next (for instance, `"[a-m-o]"`). This behavior should not be permitted, but to avoid breaking historical implementations, it is now *undefined* whether it is a valid expression and how it should be interpreted.

Current practice in *awk* and *lex* is to accept escape sequences in bracket expressions as per XBD Table 5-1 (on page 121), while the normal ERE behavior is to regard such a sequence as consisting of two characters. Allowing the *awk*/*lex* behavior in EREs would change the normal behavior in an unacceptable way; it is expected that *awk* and *lex* will decode escape sequences in EREs before passing them to *regcomp*( ) or comparable routines. Each utility describes the escape sequences it accepts as an exception to the rules in this section; the list is not the same, for historical reasons.

As noted previously, the new syntax and rules have been added to accommodate other languages than English. The remainder of this section describes the rationale for these modifications.

In the POSIX locale, a regular expression that starts with a range expression matches a set of strings that are contiguously sorted, but this is not necessarily true in other locales. For example, a French locale might have the following behavior:

```
$ ls
alpha   Alpha   estim   ESTIM   t   eurka
$ ls [a-e]*
alpha   Alpha   estim   eurka
```

Such disagreements between matching and contiguous sorting are unavoidable because POSIX

sorting cannot be implemented in terms of a deterministic finite-state automaton (DFA), but range expressions by design are implementable in terms of DFAs.

Historical implementations used native character order to interpret range expressions. The ISO POSIX-2: 1993 standard instead required collating element order (CEO): the order that collating elements were specified between the **order_start** and **order_end** keywords in the *LC_COLLATE* category of the current locale. CEO had some advantages in portability over the native character order, but it also had some disadvantages:

> CEO could not feasibly be mimicked in user code, leading to inconsistencies between POSIX matchers and matchers in popular user programs like Emacs, *ksh*, and Perl.
>
> CEO caused range expressions to match accented and capitalized letters contrary to many users' expectations. For example, `"[a-e]"` typically matched both `'E'` and `''` but neither `'A'` nor `''` .
>
> CEO was not consistent across implementations. In practice, CEO was often less portable than native character order. For example, it was common for the CEOs of two implementation-supplied locales to disagree, even if both locales were named `"da_DK"`.

Because of these problems, some implementations of regular expressions continued to use native character order. Others used the collation sequence, which is more consistent with sorting than either CEO or native order, but which departs further from the traditional POSIX semantics because it generally requires `"[a-e]"` to match either `'A'` or `'E'` but not both. As a result of this kind of implementation variation, programmers who wanted to write portable regular expressions could not rely on the ISO POSIX-2: 1993 standard guarantees in practice.

While revising the standard, lengthy consideration was given to proposals to attack this problem by adding an API for querying the CEO to allow user-mode matchers, but none of these proposals had implementation experience and none achieved consensus. Leaving the standard alone was also considered, but rejected due to the problems described above.

The current standard leaves unspecified the behavior of a range expression outside the POSIX locale. This makes it clearer that conforming applications should avoid range expressions outside the POSIX locale, and it allows implementations and compatible user-mode matchers to interpret range expressions using native order, CEO, collation sequence, or other, more advanced techniques. The concerns which led to this change were raised in IEEE PASC interpretation 1003.2 #43 and others, and related to ambiguities in the specification of how multi-character collating elements should be handled in range expressions. These ambiguities had led to multiple interpretations of the specification, in conflicting ways, which led to varying implementations. As noted above, efforts were made to resolve the differences, but no solution has been found that would be specific enough to allow for portable software while not invalidating existing implementations.

The standard developers recognize that collating elements are important, such elements being common in several European languages; for example, `'ch'` or `'ll'` in traditional Spanish; `'aa'` in several Scandinavian languages. Existing internationalized implementations have processed, and continue to process, these elements in range expressions. Efforts are expected to continue in the future to find a way to define the behavior of these elements precisely and portably.

The ISO POSIX-2: 1993 standard required `"[b-a]"` to be an invalid expression in the POSIX locale, but this requirement has been relaxed in this version of the standard so that `"[b-a]"` can instead be treated as a valid expression that does not match any string.

The standard specifies three possible behaviors for regular expressions such as `"[:alpha:]"`. One behavior is the traditional implementation, which behaves like `"[:ahlp]"`. Another, for alignment with the *tr* utility, is to treat it like `"[[:alpha:]]"`. And finally, the standard allows

rejecting the regular expression as invalid, as a means of alerting a user to the non-portable aspect of that regular expression. The set of regular expressions with this undefined behavior is limited solely to the expressions where the outer '[' and ']' of the bracket expression can be confused with the missing bracket pair '[' and ']' necessary to form a collating symbol, equivalence class, or character class; thus "[_:alpha:]" or "[::]" do not trigger the unspecified behavior.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0044 [938], XBD/TC2-2008/0045 [872], XBD/TC2-2008/0046 [938], XBD/TC2-2008/0047 [584], and XBD/TC2-2008/0048 [584] are applied.

A.9.3.6 BREs Matching Multiple Characters

The limit of nine back-references to subexpressions in the RE is based on the use of a single-digit identifier; increasing this to multiple digits would break historical applications. This does not imply that only nine subexpressions are allowed in REs. The following is a valid BRE with ten subexpressions:

```
\(\(\(ab\)*c\)*d\)\(ef\)*\(gh\)\{2\}\(ij\)*\(kl\)*\(mn\)*\(op\)*\(qr\)*
```

The standard developers regarded the common historical behavior, which supported "\n*", but not "\n\{min,max\}", "\(...\)*", or "\(...\)\{min,max\}", as a non-intentional result of a specific implementation, and they supported both duplication and interval expressions following subexpressions and back-references.

The changes to the processing of the back-reference expression remove an unspecified or ambiguous behavior in the Shell and Utilities volume of POSIX.1-2017, aligning it with the requirements specified for the *regcomp*() expression, and is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2: 1993 standard.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0049 [595] is applied.

A.9.3.7 BRE Precedence

There is no additional rationale provided for this section.

A.9.3.8 BRE Expression Anchoring

Often, the <dollar-sign> is viewed as matching the ending <newline> in text files. This is not strictly true; the <newline> is typically eliminated from the strings to be matched, and the <dollar-sign> matches the terminating null character.

The ability of '^', '$', and '*' to be non-special in certain circumstances may be confusing to some programmers, but this situation was changed only in a minor way from historical practice to avoid breaking many historical scripts. Some consideration was given to making the use of the anchoring characters undefined if not escaped and not at the beginning or end of strings. This would cause a number of historical BREs, such as "2^10", "$HOME", and "$1.35", that relied on the characters being treated literally, to become invalid.

However, one relatively uncommon case was changed to allow an extension used on some implementations. Historically, the BREs "^foo" and "\(^foo\)" did not match the same string, despite the general rule that subexpressions and entire BREs match the same strings. To increase consensus, POSIX.1-2017 has allowed an extension on some implementations to treat these two cases in the same way by declaring that anchoring *may* occur at the beginning or end of a subexpression. Therefore, portable BREs that require a literal <circumflex> at the beginning or a <dollar-sign> at the end of a subexpression must escape them. Note that a BRE such as

"a\(^bc\)" will either match "a^bc" or nothing on different systems under the rules.

ERE anchoring has been different from BRE anchoring in all historical systems. An unescaped anchor character has never matched its literal counterpart outside a bracket expression. Some implementations treated "foo$bar" as a valid expression that never matched anything; others treated it as invalid. POSIX.1-2017 mandates the former, valid unmatched behavior.

Some implementations have extended the BRE syntax to add alternation. For example, the subexpression "\(foo$\|bar\)" would match either "foo" at the end of the string or "bar" anywhere. The extension is triggered by the use of the undefined "\|" sequence. Because the BRE is undefined for portable scripts, the extending system is free to make other assumptions, such that the '$' represents the end-of-line anchor in the middle of a subexpression. If it were not for the extension, the '$' would match a literal <dollar-sign> under the rules.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0049 [595] is applied.

A.9.4 Extended Regular Expressions

As with BREs, the standard developers decided to make the interpretation of escaped ordinary characters undefined.

The <right-parenthesis> is not listed as an ERE special character because it is only special in the context of a preceding <left-parenthesis>. If found without a preceding <left-parenthesis>, the <right-parenthesis> has no special meaning.

The interval expression, "{m,n}", has been added to EREs. Historically, the interval expression has only been supported in some ERE implementations. The standard developers estimated that the addition of interval expressions to EREs would not decrease consensus and would also make BREs more of a subset of EREs than in many historical implementations.

It was suggested that, in addition to interval expressions, back-references ('\n') should also be added to EREs. This was rejected by the standard developers as likely to decrease consensus.

In historical implementations, multiple duplication symbols are usually interpreted from left to right and treated as additive. As an example, "a+*b" matches zero or more instances of 'a' followed by a 'b'. In POSIX.1-2017, multiple duplication symbols are undefined; that is, they cannot be relied upon for conforming applications. One reason for this is to provide some scope for future enhancements.

The precedence of operations differs between EREs and those in *lex*; in *lex*, for historical reasons, interval expressions have a lower precedence than concatenation.

A.9.4.1 EREs Matching a Single Character or Collating Element

There is no additional rationale provided for this section.

A.9.4.2 ERE Ordinary Characters

120278 ### A.9.5 Regular Expression Grammar

120279 The grammars are intended to represent the range of acceptable syntaxes available to
120280 conforming applications. There are instances in the text where undefined constructs are
120281 described; as explained previously, these allow implementation extensions. There is no intended
120282 requirement that an implementation extension must somehow fit into the grammars shown
120283 here.

120284 The BRE grammar does not permit L_ANCHOR or R_ANCHOR inside `"\("` and `"\)"` (which
120285 implies that `'^'` and `'$'` are ordinary characters). This reflects the semantic limits on the
120286 application, as noted in XBD Section 9.3.8 (on page 188). Implementations are permitted to
120287 extend the language to interpret `'^'` and `'$'` as anchors in these locations, and as such,
120288 conforming applications cannot use unescaped `'^'` and `'$'` in positions inside `"\("` and `"\)"`
120289 that might be interpreted as anchors.

120290 The ERE grammar does not permit several constructs that XBD Section 9.4.2 (on page 188) and
120291 Section 9.4.3 (on page 189) specify as having undefined results:

120292 ORD_CHAR preceded by <backslash>

120293 *ERE_dupl_symbol*(s) appearing first in an ERE, or immediately following `'|'`, `'^'`, or `'('`

120294 `'{'` not part of a valid *ERE_dupl_symbol*

'|' appearing first or last in an ERE, or immediately following '|' or '(', or immediately preceding ')'

Implementations are permitted to extend the language to allow these. Conforming applications cannot use such constructs.

A.9.5.1 BRE/ERE Grammar Lexical Conventions

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0052 [554] is applied.

A.9.5.2 RE and Bracket Expression Grammar

The removal of the *Back_open_paren Back_close_paren* option from the *nondupl_RE* specification is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2: 1993 standard. Although the grammar required support for null subexpressions, this section does not describe the meaning of, and historical practice did not support, this construct.

A.9.5.3 ERE Grammar

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0052 [554] and XBD/TC2-2008/0053 [916] are applied.

A.10 Directory Structure and Devices

A.10.1 Directory Structure and Files

A description of the historical **/usr/tmp** was omitted, removing any concept of differences in emphasis between the **/** and **/usr** directories. The descriptions of **/bin**, **/usr/bin**, **/lib**, and **/usr/lib** were omitted because they are not useful for applications. In an early draft, a distinction was made between system and application directory usage, but this was not found to be useful.

The directories **/** and **/dev** are included because the notion of a hierarchical directory structure is key to other information presented elsewhere in POSIX.1-2017. In early drafts, it was argued that special devices and temporary files could conceivably be handled without a directory structure on some implementations. For example, the system could treat the characters "/tmp" as a special token that would store files using some non-POSIX file system structure. This notion was rejected by the standard developers, who required that all the files in this section be implemented via POSIX file systems.

The **/tmp** directory is retained in POSIX.1-2017 to accommodate historical applications that assume its availability. Implementations are encouraged to provide suitable directory names in the environment variable *TMPDIR* and applications are encouraged to use the contents of *TMPDIR* for creating temporary files.

The standard files **/dev/null** and **/dev/tty** are required to be both readable and writable to allow applications to have the intended historical access to these files.

The standard file **/dev/console** has been added for alignment with the Single UNIX Specification.

A.10.2 Output Devices and Terminal Types

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/17 is applied, making it clear that the requirements for documenting terminal support are in the system documentation.

POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0054 [967] is applied.

A.11 General Terminal Interface

If the implementation does not support this interface on any device types, it should behave as if it were being used on a device that is not a terminal device (in most cases *errno* will be set to [ENOTTY] on return from functions defined by this interface). This is based on the fact that many applications are written to run both interactively and in some non-interactive mode, and they adapt themselves at runtime. Requiring that they all be modified to test an environment variable to determine whether they should try to adapt is unnecessary. On a system that provides no general terminal interface, providing all the entry points as stubs that return [ENOTTY] (or an equivalent, as appropriate) has the same effect and requires no changes to the application.

Although the needs of both interface implementors and application developers were addressed throughout POSIX.1-2017, this section pays more attention to the needs of the latter. This is because, while many aspects of the programming interface can be hidden from the user by the application developer, the terminal interface is usually a large part of the user interface. Although to some extent the application developer can build missing features or work around inappropriate ones, the difficulties of doing that are greater in the terminal interface than elsewhere. For example, efficiency prohibits the average program from interpreting every character passing through it in order to simulate character erase, line kill, and so on. These functions should usually be done by the operating system, possibly at the interrupt level.

The *tc**() functions were introduced as a way of avoiding the problems inherent in the traditional *ioctl*() function and in variants of it that were proposed. For example, *tcsetattr*() is specified in place of the use of the TCSETA *ioctl*() command function. This allows specification of all the arguments in a manner consistent with the ISO C standard unlike the varying third argument of *ioctl*(), which is sometimes a pointer (to any of many different types) and sometimes an **int**.

The advantages of this new method include:

- It allows strict type checking.
- The direction of transfer of control data is explicit.
- Portable capabilities are clearly identified.
- The need for a general interface routine is avoided.
- Size of the argument is well-defined (there is only one type).

The disadvantages include:

- No historical implementation used the new method.
- There are many small routines instead of one general-purpose one.
- The historical parallel with *fcntl*() is broken.

The issue of modem control was excluded from POSIX.1-2017 on the grounds that:

120370 It was concerned with setting and control of hardware timers.

120371 The appropriate timers and settings vary widely internationally.

120372 Feedback from European computer manufacturers indicated that this facility was not
120373 consistent with European needs and that specification of such a facility was not a
120374 requirement for portability.

120375 A.11.1 Interface Characteristics

120376 *A.11.1.1 Opening a Terminal Device File*

120377 The O_TTY_INIT flag for *open*() has been added to POSIX.1-2017 to solve a problem
120378 encountered by applications written for earlier versions of this standard which need to open a
120379 modem or similar device and initialize all of the parameter settings. Using the
120380 *tcgetattr*()-modify-*tcsetattr*() method mandated by the standard could result in non-conforming
120381 behavior if the device had previously been used with non-conforming parameter settings, on
120382 implementations which do not reset the parameter settings in between the last close of the
120383 device by one application and the first open by another application. To avoid this problem, some
120384 application developers were resorting to using *memset*() to zero the **termios** structure before
120385 setting all of the standard parameters, but this risks non-conforming behavior on systems where
120386 some non-standard parameter needs a non-zero value in order for the terminal to behave in a
120387 conforming manner.

120388 On systems which do reset the parameter settings to defaults between uses of a terminal device,
120389 it is expected that either O_TTY_INIT will have the value zero or *open*(*ttypath*,
120390 O_RDWR|O_TTY_INIT) will do nothing additional.

120391 The standard developers considered an alternative solution of a special *fildes* argument for the
120392 *tcgetattr*() call to obtain default parameters. However, this would not be adequate if a system
120393 supports several different types of terminal device and the default settings need to differ
120394 between the different types. With the O_TTY_INIT open flag, the implementor can determine
120395 which device type is being opened.

120396 The standard developers also considered a special POSIX_TTY_INIT value for the **termios**
120397 structure used in *tcsetattr*(), which would reset the values if used immediately after an *open*()
120398 call. However, it was felt that this would lead to confusion amongst application developers who
120399 wanted to reset the parameters at other points, and implementations might diverge.

120400 *A.11.1.2 Process Groups*

120401 There is a potential race when the members of the foreground process group on a terminal leave
120402 that process group, either by exit or by changing process groups. After the last process exits the
120403 process group, but before the foreground process group ID of the terminal is changed (usually
120404 by a job control shell), it would be possible for a new process to be created with its process ID
120405 equal to the terminal's foreground process group ID. That process might then become the
120406 process group leader and accidentally be placed into the foreground on a terminal that was not
120407 necessarily its controlling terminal. As a result of this problem, the controlling terminal is
120408 defined to not have a foreground process group during this time.

120409 The cases where a controlling terminal has no foreground process group occur when all
120410 processes in the foreground process group either terminate and are waited for or join other
120411 process groups via *setpgid*() or *setsid*(). If the process group leader terminates, this is the first

120412 case described; if it leaves the process group via *setpgid*(), this is the second case described (a
120413 process group leader cannot successfully call *setsid*()). When one of those cases causes a
120414 controlling terminal to have no foreground process group, it has two visible effects on
120415 applications. The first is the value returned by *tcgetpgrp*(). The second (which occurs only in the
120416 case where the process group leader terminates) is the sending of signals in response to special
120417 input characters. The intent of POSIX.1-2017 is that no process group be wrongly identified as
120418 the foreground process group by *tcgetpgrp*() or unintentionally receive signals because of
120419 placement into the foreground.

120420 In 4.3 BSD, the old process group ID continues to be used to identify the foreground process
120421 group and is returned by the function equivalent to *tcgetpgrp*(). In that implementation it is
120422 possible for a newly created process to be assigned the same value as a process ID and then form
120423 a new process group with the same value as a process group ID. The result is that the new
120424 process group would receive signals from this terminal for no apparent reason, and
120425 POSIX.1-2017 precludes this by forbidding a process group from entering the foreground in this
120426 way. It would be more direct to place part of the requirement made by the last sentence under
120427 *fork*(), but there is no convenient way for that section to refer to the value that *tcgetpgrp*()
120428 returns, since in this case there is no process group and thus no process group ID.

120429 One possibility for a conforming implementation is to behave similarly to 4.3 BSD, but to
120430 prevent this reuse of the ID, probably in the implementation of *fork*(), as long as it is in use by
120431 the terminal.

120432 Another possibility is to recognize when the last process stops using the terminal's foreground
120433 process group ID, which is when the process group lifetime ends, and to change the terminal's
120434 foreground process group ID to a reserved value that is never used as a process ID or process
120435 group ID. (See the definition of *process group lifetime* in the definitions section.) The process ID
120436 can then be reserved until the terminal has another foreground process group.

120437 The 4.3 BSD implementation permits the leader (and only member) of the foreground process
120438 group to leave the process group by calling the equivalent of *setpgid*() and to later return,
120439 expecting to return to the foreground. There are no known application needs for this behavior,
120440 and POSIX.1-2017 neither requires nor forbids it (except that it is forbidden for session leaders)
120441 by leaving it unspecified.

120442 *A.11.1.3 The Controlling Terminal*

120443 POSIX.1-2017 does not specify a mechanism by which to allocate a controlling terminal. This is
120444 normally done by a system utility (such as *getty*) and is considered an administrative feature
120445 outside the scope of POSIX.1-2017.

120446 Historical implementations allocate controlling terminals on certain *open*() calls. Since *open*() is
120447 part of POSIX.1, its behavior had to be dealt with. The traditional behavior is not required
120448 because it is not very straightforward or flexible for either implementations or applications.
120449 However, because of its prevalence, it was not practical to disallow this behavior either. Thus, a
120450 mechanism was standardized to ensure portable, predictable behavior in *open*().

120451 Some historical implementations deallocate a controlling terminal on the last system-wide close.
120452 This behavior in neither required nor prohibited. Even on implementations that do provide this
120453 behavior, applications generally cannot depend on it due to its system-wide nature.

120454 *A.11.1.4 Terminal Access Control*

120455 The access controls described in this section apply only to a process that is accessing its
120456 controlling terminal. A process accessing a terminal that is not its controlling terminal is
120457 effectively treated the same as a member of the foreground process group. While this may seem
120458 unintuitive, note that these controls are for the purpose of job control, not security, and job
120459 control relates only to the controlling terminal of a process. Normal file access permissions
120460 handle security.

120461 If the process calling *read*() or *write*() is in a background process group that is orphaned, it is not
120462 desirable to stop the process group, as it is no longer under the control of a job control shell that
120463 could put it into the foreground again. Accordingly, calls to *read*() or *write*() functions by such
120464 processes receive an immediate error return. This is different from 4.2 BSD, which kills orphaned
120465 processes that receive terminal stop signals.

120466 The foreground/background/orphaned process group check performed by the terminal driver
120467 must be repeatedly performed until the calling process moves into the foreground or until the
120468 process group of the calling process becomes orphaned. That is, when the terminal driver
120469 determines that the calling process is in the background and should receive a job control signal,
120470 it sends the appropriate signal (SIGTTIN or SIGTTOU) to every process in the process group of
120471 the calling process and then it allows the calling process to immediately receive the signal. The
120472 latter is typically performed by blocking the process so that the signal is immediately noticed.
120473 Note, however, that after the process finishes receiving the signal and control is returned to the
120474 driver, the terminal driver must re-execute the foreground/background/orphaned process
120475 group check. The process may still be in the background, either because it was continued in the
120476 background by a job control shell, or because it caught the signal and did nothing.

120477 The terminal driver repeatedly performs the foreground/background/orphaned process group
120478 checks whenever a process is about to access the terminal. In the case of *write*() or the control
120479 *tc**() functions, the check is performed at the entry of the function. In the case of *read*(), the
120480 check is performed not only at the entry of the function, but also after blocking the process to
120481 wait for input characters (if necessary). That is, once the driver has determined that the process
120482 calling the *read*() function is in the foreground, it attempts to retrieve characters from the input
120483 queue. If the queue is empty, it blocks the process waiting for characters. When characters are
120484 available and control is returned to the driver, the terminal driver must return to the repeated
120485 foreground/background/orphaned process group check again. The process may have moved
120486 from the foreground to the background while it was blocked waiting for input characters.

120487 *A.11.1.5 Input Processing and Reading Data*

120488 There is no additional rationale provided for this section.

120489 *A.11.1.6 Canonical Mode Input Processing*

120490 The term ``character'' is intended here. ERASE should erase the last character, not the last byte.
120491 In the case of multi-byte characters, these two may be different.

120492 4.3 BSD has a WERASE character that erases the last ``word'' typed (but not any preceding
120493 <blank> or <tab> characters). A word is defined as a sequence of non-<blank> characters, with
120494 <tab> characters counted as <blank> characters. Like ERASE, WERASE does not erase beyond
120495 the beginning of the line. This WERASE feature has not been specified in POSIX.1 because it is
120496 difficult to define in the international environment. It is only useful for languages where words
120497 are delimited by <blank> characters. In some ideographic languages, such as Japanese and
120498 Chinese, words are not delimited at all. The WERASE character should presumably go back to
120499 the beginning of a sentence in those cases; practically, this means it would not be used much for

120500 those languages.

120501 It should be noted that there is a possible inherent deadlock if the application and
120502 implementation conflict on the value of {MAX_CANON}. With ICANON set (if IXOFF is
120503 enabled) and more than {MAX_CANON} characters transmitted without a <linefeed>,
120504 transmission will be stopped, the <linefeed> (or <carriage-return> when ICRLF is set) will never
120505 arrive, and the *read*( ) will never be satisfied.

120506 An application should not set IXOFF if it is using canonical mode unless it knows that (even in
120507 the face of a transmission error) the conditions described previously cannot be met or unless it is
120508 prepared to deal with the possible deadlock in some other way, such as timeouts.

120509 It should also be noted that this can be made to happen in non-canonical mode if the trigger
120510 value for sending IXOFF is less than VMIN and VTIME is zero.

120511 *A.11.1.7 Non-Canonical Mode Input Processing*

120512 Some points to note about MIN and TIME:

120513 1. The interactions of MIN and TIME are not symmetric. For example, when MIN>0 and
120514 TIME=0, TIME has no effect. However, in the opposite case where MIN=0 and TIME>0,
120515 both MIN and TIME play a role in that MIN is satisfied with the receipt of a single
120516 character.

120517 2. Also note that in case A (MIN>0, TIME>0), TIME represents an inter-character timer,
120518 while in case C (MIN=0, TIME>0), TIME represents a read timer.

120519 These two points highlight the dual purpose of the MIN/TIME feature. Cases A and B, where
120520 MIN>0, exist to handle burst-mode activity (for example, file transfer programs) where a
120521 program would like to process at least MIN characters at a time. In case A, the inter-character
120522 timer is activated by a user as a safety measure; in case B, it is turned off.

120523 Cases C and D exist to handle single-character timed transfers. These cases are readily adaptable
120524 to screen-based applications that need to know if a character is present in the input queue before
120525 refreshing the screen. In case C, the read is timed; in case D, it is not.

120526 Another important note is that MIN is always just a minimum. It does not denote a record
120527 length. That is, if a program does a read of 20 bytes, MIN is 10, and 25 characters are present, 20
120528 characters are returned to the user. In the special case of MIN=0, this still applies: if more than
120529 one character is available, they all will be returned immediately.

120530 *A.11.1.8 Writing Data and Output Processing*

120531 There is no additional rationale provided for this section.

120532 *A.11.1.9 Special Characters*

120533 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0055 [745] is applied.

120534 *A.11.1.10 Modem Disconnect*

120535 There is no additional rationale provided for this section.

120536 *A.11.1.11 Closing a Terminal Device File*

120537 POSIX.1-2017 does not specify that a *close*( ) on a terminal device file include the equivalent of a
120538 call to *tcflow*(*fd*,TCOON).

120539 An implementation that discards output at the time *close*( ) is called after reporting the return
120540 value to the *write*( ) call that data was written does not conform with POSIX.1-2017. An
120541 application has functions such as *tcdrain*( ), *tcflush*( ), and *tcflow*( ) available to obtain the detailed
120542 behavior it requires with respect to flushing of output.

120543 At the time of the last close on a terminal device, an application relinquishes any ability to exert
120544 flow control via *tcflow*( ).

120545 ## A.11.2 Parameters that Can be Set

120546 *A.11.2.1 The termios Structure*

120547 This structure is part of an interface that, in general, retains the historic grouping of flags.
120548 Although a more optimal structure for implementations may be possible, the degree of change
120549 to applications would be significantly larger.

120550 *A.11.2.2 Input Modes*

120551 Some historical implementations treated a long break as multiple events, as many as one per
120552 character time. The wording in POSIX.1 explicitly prohibits this.

120553 Although the ISTRIP flag is normally superfluous with today's terminal hardware and software,
120554 it is historically supported. Therefore, applications may be using ISTRIP, and there is no
120555 technical problem with supporting this flag. Also, applications may wish to receive only 7-bit
120556 input bytes and may not be connected directly to the hardware terminal device (for example,
120557 when a connection traverses a network).

120558 Also, there is no requirement in general that the terminal device ensures that high-order bits
120559 beyond the specified character size are cleared. ISTRIP provides this function for 7-bit
120560 characters, which are common.

120561 In dealing with multi-byte characters, the consequences of a parity error in such a character, or
120562 in an escape sequence affecting the current character set, are beyond the scope of POSIX.1 and
120563 are best dealt with by the application processing the multi-byte characters.

120564 *A.11.2.3 Output Modes*

120565 POSIX.1 does not describe post-processing of output to a terminal or detailed control of that
120566 from a conforming application. (That is, translation of <newline> to <carriage-return> followed
120567 by <linefeed> or <tab> processing.) There is nothing that a conforming application should do to
120568 its output for a terminal because that would require knowledge of the operation of the terminal.
120569 It is the responsibility of the operating system to provide post-processing appropriate to the
120570 output device, whether it is a terminal or some other type of device.

120571 Extensions to POSIX.1 to control the type of post-processing already exist and are expected to
120572 continue into the future. The control of these features is primarily to adjust the interface between
120573 the system and the terminal device so the output appears on the display correctly. This should
120574 be set up before use by any application.

120575 In general, both the input and output modes should not be set absolutely, but rather modified
120576 from the inherited state.

120577 *A.11.2.4 Control Modes*

120578 This section could be misread that the symbol ``CSIZE'' is a title in the **termios** *c_cflag* field.
120579 Although it does serve that function, it is also a required symbol, as a literal reading of POSIX.1
120580 (and the caveats about typography) would indicate.

120581 *A.11.2.5 Local Modes*

120582 Non-canonical mode is provided to allow fast bursts of input to be read efficiently while still
120583 allowing single-character input.

120584 The ECHONL function historically has been in many implementations. Since there seems to be
120585 no technical problem with supporting ECHONL, it is included in POSIX.1 to increase consensus.

120586 The alternate behavior possible when ECHOK or ECHOE are specified with ICANON is
120587 permitted as a compromise depending on what the actual terminal hardware can do. Erasing
120588 characters and lines is preferred, but is not always possible.

120589 *A.11.2.6 Special Control Characters*

120590 Permitting VMIN and VTIME to overlap with VEOF and VEOL was a compromise for historical
120591 implementations. Only when backwards-compatibility of object code is a serious concern to an
120592 implementor should an implementation continue this practice. Correct applications that work
120593 with the overlap (at the source level) should also work if it is not present, but not the reverse.

120594 A.12 Utility Conventions

120595 A.12.1 Utility Argument Syntax

120596 The standard developers considered that recent trends toward diluting the SYNOPSIS sections
120597 of historical reference pages to the equivalent of:

120598 `command [`*`options`*`][`*`operands`*`]`

120599 were a disservice to the reader. Therefore, considerable effort was placed into rigorous
120600 definitions of all the command line arguments and their interrelationships. The relationships
120601 depicted in the synopses are normative parts of POSIX.1-2017; this information is sometimes
120602 repeated in textual form, but that is only for clarity within context.

120603 The use of ``undefined'' for conflicting argument usage and for repeated usage of the same
120604 option is meant to prevent conforming applications from using conflicting arguments or
120605 repeated options unless specifically allowed (as is the case with *ls*, which allows simultaneous,
120606 repeated use of the **−C**, **−l**, and **−1** options). Many historical implementations will tolerate this
120607 usage, choosing either the first or the last applicable argument. This tolerance can continue, but
120608 conforming applications cannot rely upon it. (Other implementations may choose to print usage
120609 messages instead.)

120610 The use of ``undefined'' for conflicting argument usage also allows an implementation to make

120611 reasonable extensions to utilities where the implementor considers mutually-exclusive options
120612 according to POSIX.1-2017 to have a sensible meaning and result.

120613 POSIX.1-2017 does not define the result of a command when an option-argument or operand is
120614 not followed by ellipses and the application specifies more than one of that option-argument or
120615 operand. This allows an implementation to define valid (although non-standard) behavior for
120616 the utility when more than one such option or operand is specified.

120617 The requirements for option-arguments are summarized as follows:

120618 | | **SYNOPSIS Shows:** | |
120619 | | `-a arg` | `-c[arg]` |
120620 | Conforming application uses: | `-a arg` | `-carg` or `-c` |
120621 | System supports: | `-a arg` and `-aarg` | `-carg` and `-c` |
120622 | Non-conforming applications may use: | `-aarg` | N/A |

120623 Earlier versions of this standard included obsolescent syntax which showed some options with
120624 (mandatory) adjacent option-arguments in the SYNOPSIS for some utilities. These have since
120625 been removed. For all options with mandatory option-arguments, the SYNOPSIS now shows
120626 <blank> characters between the option and the option-argument; however, historical usage has
120627 not been consistent in this area; therefore, <blank> characters are required to be used by
120628 conforming applications and to be handled by all implementations, but implementations are
120629 also required to handle an adjacent option-argument in order to preserve backwards-
120630 compatibility for old scripts. One of the justifications for selecting the multiple-argument
120631 method was that the single-argument case is inherently ambiguous when the option-argument
120632 can legitimately be a null string.

120633 POSIX.1-2017 explicitly states that digits are permitted as operands and option-arguments. The
120634 lower and upper bounds for the values of the numbers used for operands and option-arguments
120635 were derived from the ISO C standard values for {LONG_MIN} and {LONG_MAX}. The
120636 requirement on the standard utilities is that numbers in the specified range do not cause a
120637 syntax error, although the specification of a number need not be semantically correct for a
120638 particular operand or option-argument of a utility. For example, the specification of:

120639 `dd obs=3000000000`

120640 would yield undefined behavior for the application and could be a syntax error because the
120641 number 3 000 000 000 is outside of the range –2 147 483 647 to +2 147 483 647. On the other hand:

120642 `dd obs=2000000000`

120643 may cause some error, such as ``blocksize too large'', rather than a syntax error.

120644 POSIX.1-2008, Technical Corrigendum 2, XBD/TC2-2008/0056 [584] and XBD/TC2-2008/0057
120645 [813] are applied.

120646 A.12.2 Utility Syntax Guidelines

120647 This section is based on the rules listed in the SVID. It was included for two reasons:

120648 1. The individual utility descriptions in XCU Chapter 4 (on page 2453) needed a set of
120649 common (although not universal) actions on which they could anchor their descriptions
120650 of option and operand syntax. Most of the standard utilities actually do use these
120651 guidelines, and many of their historical implementations use the *getopt*() function for
120652 their parsing. Therefore, it was simpler to cite the rules and merely identify exceptions.

2. Developers of conforming applications need suggested guidelines if the POSIX community is to avoid the chaos of historical UNIX system command syntax.

It is recommended that all *future* utilities and applications use these guidelines to enhance ``user portability''. The fact that some historical utilities could not be changed (to avoid breaking historical applications) should not deter this future goal.

The voluntary nature of the guidelines is highlighted by repeated uses of the word *should* throughout. This usage should not be misinterpreted to imply that utilities that claim conformance in their OPTIONS sections do not always conform.

Guidelines 1 and 2 encourage utility writers to use only characters from the portable character set because use of locale-specific characters may make the utility inaccessible from other locales. Use of uppercase letters is discouraged due to problems associated with porting utilities to systems that do not distinguish between uppercase and lowercase characters in filenames. Use of non-alphanumeric characters is discouraged due to the number of utilities that treat non-alphanumeric characters in ``special'' ways depending on context (such as the shell using white-space characters to delimit arguments, various quote characters for quoting, the <dollar-sign> to introduce variable expansion, etc.).

In XCU Section 2.9.1 (on page 2365), it is further stated that a command used in the Shell Command Language cannot be named with a trailing <colon>.

Guideline 3 was changed to allow alphanumeric characters (letters and digits) from the character set to allow compatibility with historical usage. Historical practice allows the use of digits wherever practical, and there are no portability issues that would prohibit the use of digits. In fact, from an internationalization viewpoint, digits (being non-language-dependent) are preferable over letters (a **−2** is intuitively self-explanatory to any user, while in the **−f** *filename* the letter `'f'` is a mnemonic aid only to speakers of Latin-based languages where ``filename'' happens to translate to a word that begins with `'f'`. Since Guideline 3 still retains the word ``single'', multi-digit options are not allowed. Instances of historical utilities that used them have been marked obsolescent, with the numbers being changed from option names to option-arguments.

It was difficult to achieve a satisfactory solution to the problem of name space in option characters. When the standard developers desired to extend the historical *cc* utility to accept ISO C standard programs, they found that all of the portable alphabet was already in use by various vendors. Thus, they had to devise a new name, *c89* (now superseded by *c99*), rather than something like *cc* **−X**. There were suggestions that implementors be restricted to providing extensions through various means (such as using a <plus-sign> as the option delimiter or using option characters outside the alphanumeric set) that would reserve all of the remaining alphanumeric characters for future POSIX standards. These approaches were resisted because they lacked the historical style of UNIX systems. Furthermore, if a vendor-provided option should become commonly used in the industry, it would be a candidate for standardization. It would be desirable to standardize such a feature using historical practice for the syntax (the semantics can be standardized with any syntax). This would not be possible if the syntax was one reserved for the vendor. However, since the standardization process may lead to minor changes in the semantics, it may prove to be better for a vendor to use a syntax that will not be affected by standardization.

Guideline 8 includes the concept of <comma>-separated lists in a single argument. It is up to the utility to parse such a list itself because *getopt*( ) just returns the single string. This situation was retained so that certain historical utilities would not violate the guidelines. Applications preparing for international use should be aware of an occasional problem with <comma>-separated lists: in some locales, the <comma> is used as the radix character. Thus, if an application is preparing operands for a utility that expects a <comma>-separated list, it

should avoid generating non-integer values through one of the means that is influenced by setting the *LC_NUMERIC* variable (such as *awk*, *bc*, *printf*, or *printf*( )).

Unless explicitly stated otherwise in the utility description, Guideline 9 requires applications to put options before operands, and requires utilities to accept any such usage without misinterpreting operands as options. For example, if an implementation of the *printf* utility supports a **−e** option as an extension, the command:

```
printf %s -e
```

must output the string `"-e"` without interpreting the **−e** as an option. Similarly, the command:

```
ls myfile -l
```

must interpret the **−l** argument as a second file operand, not as a **−l** option.

Applications calling any utility with a first operand starting with `'-'` should usually specify **−−**, as indicated by Guideline 10, to mark the end of the options. This is true even if the SYNOPSIS in the Shell and Utilities volume of POSIX.1-2017 does not specify any options; implementations may provide options as extensions to the Shell and Utilities volume of POSIX.1-2017. The standard utilities that do not support Guideline 10 indicate that fact in the OPTIONS section of the utility description.

Guideline 7 allows any string to be an option-argument; an option-argument can begin with any character, can be **−** or **−−**, and can be an empty string. For example, the commands *pr* **−h −**, *pr* **−h −−**, *pr* **−h −d**, *pr* **−h +2**, and *pr* **−h ''** contain the option-arguments **−**, **−−**, **−d**, **+2**, and an empty string, respectively. Conversely, the command *pr* **−h −− −d** treats **−d** as an option, not as an argument, because the **−−** is an option-argument here, not a delimiter.

Guideline 11 was modified to clarify that the order of different options should not matter relative to one another. However, the order of repeated options that also have option-arguments may be significant; therefore, such options are required to be interpreted in the order that they are specified. The *make* utility is an instance of a historical utility that uses repeated options in which the order is significant. Multiple files are specified by giving multiple instances of the **−f** option; for example:

```
make −f common_header −f specific_rules target
```

Guideline 13 does not imply that all of the standard utilities automatically accept the operand `'-'` to mean standard input or output, nor does it specify the actions of the utility upon encountering multiple `'-'` operands. It simply says that, by default, `'-'` operands are not used for other purposes in the file reading or writing (but not when using *stat*( ), *unlink*( ), *touch*, and so on) utilities. In earlier versions of this standard, all information concerning actual treatment of the `'-'` operand is found in the individual utility sections. Many implementations, however, treated `'-'` as standard input or output and many applications depended on this behavior even though it was not standard. This behavior is now implementation-defined. Portable applications should not use `'-'` to mean standard input or output unless it is explicitly stated to do so in the utility description and they should always use `'./-'` if they intend to refer to a file named **−** in the current working directory.

Guideline 14 is intended to prohibit implementations that would treat the command *ls* **−l −d** as if it were *ls* **−− −l −d** or *ls* **−l −− −d**.

The standard permits implementations to have extensions that violate the Utility Syntax Guidelines so long as when the utility is used in line with the forms defined by the standard it follows the Utility Syntax Guidelines. Thus, head*−42*file and *ls*−−help are permitted extensions. The intent is to allow extensions so long as the standard form is accepted and follows the guidelines.

An area of concern was that as implementations mature, implementation-defined utilities and implementation-defined utility options will result. The idea was expressed that there needed to be a standard way, say an environment variable or some such mechanism, to identify implementation-defined utilities separately from standard utilities that may have the same name. It was decided that there already exist several ways of dealing with this situation and that it is outside of the scope to attempt to standardize in the area of non-standard items. A method that exists on some historical implementations is the use of the so-called **/local/bin** or **/usr/local/bin** directory to separate local or additional copies or versions of utilities. Another method that is also used is to isolate utilities into completely separate domains. Still another method to ensure that the desired utility is being used is to request the utility by its full pathname. There are many approaches to this situation; the examples given above serve to illustrate that there is more than one.

A.13 Headers

A.13.1 Format of Entries

Each header reference page has a common layout of sections describing the interface. This layout is similar to the manual page or ``man'' page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS and DESCRIPTION. These are the two sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. APPLICATION USAGE sections provide additional caveats, issues, and recommendations to the developer. RATIONALE sections give additional information on the decisions made in defining the interface.

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

The CHANGE HISTORY section describes when the interface was introduced, and how it has changed.

Option labels and margin markings in the page can be useful in guiding the application developer.

A.13.2 Removed Headers in Issue 7

The headers removed in Issue 7 (from the Issue 6 base document) are as follows:

Removed Headers in Issue 7

Rationale (Informative)

Part B:

System Interfaces

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

120787 *Appendix B*

120788 # *Rationale for System Interfaces*

120789 ## B.1 Introduction

120790 ### B.1.1 Change History

120791 The change history is provided as an informative section, to track changes from earlier versions
120792 of this standard.

120793 The following sections describe changes made to the System Interfaces volume of POSIX.1-2017
120794 since Issue 6 of the base document. The CHANGE HISTORY section for each entry details the
120795 technical changes that have been made to that entry from Issue 5. Changes between earlier
120796 versions of the base document and Issue 5 are not included.

120797 **Changes from Issue 6 to Issue 7 (POSIX.1-2008)**

120798 The following list summarizes the major changes that were made in the System Interfaces
120799 volume of POSIX.1-2017 from Issue 6 to Issue 7:

120800 The Open Group Technical Standard, 2006, Extended API Set Part 1 is incorporated.

120801 The Open Group Technical Standard, 2006, Extended API Set Part 2 is incorporated.

120802 The Open Group Technical Standard, 2006, Extended API Set Part 3 is incorporated.

120803 The Open Group Technical Standard, 2006, Extended API Set Part 4 is incorporated.

120804 Existing functionality is aligned with ISO/IEC 9899:1999, Programming Languages — C,
120805 ISO/IEC 9899:1999/Cor.2:2004(E)

120806 Austin Group defect reports, IEEE Interpretations against IEEE Std 1003.1, and responses
120807 to ISO/IEC defect reports against ISO/IEC 9945 are applied.

120808 The Open Group corrigenda and resolutions are applied.

120809 Features, marked legacy or obsolescent in the base document, have been considered for
120810 removal in this version.

120811 The options within the standard have been revised.

120812 **New Features in Issue 7**

120813 The functions first introduced in Issue 7 (over the Issue 6 base document) are as follows:

120814

New Functions in Issue 7		
120815 *alphasort*()	*iswdigit_l*()	*strfmon_l*()
120816 *dirfd*()	*iswgraph_l*()	*strncasecmp_l*()
120817 *dprintf*()	*iswlower_l*()	*strndup*()
120818 *duplocale*()	*iswprint_l*()	*strnlen*()
120819 *faccessat*()	*iswpunct_l*()	*strsignal*()
120820 *fchmodat*()	*iswspace_l*()	*strxfrm_l*()
120821 *fchownat*()	*iswupper_l*()	*symlinkat*()
120822 *fdopendir*()	*iswxdigit_l*()	*tolower_l*()
120823 *fexecve*()	*isxdigit_l*()	*toupper_l*()
120824 *fmemopen*()	*linkat*()	*towctrans_l*()
120825 *freelocale*()	*mbsnrtowcs*()	*towlower_l*()
120826 *fstatat*()	*mkdirat*()	*towupper_l*()
120827 *futimens*()	*mkdtemp*()	*unlinkat*()
120828 *getdelim*()	*mkfifoat*()	*uselocale*()
120829 *getline*()	*mknodat*()	*utimensat*()
120830 *isalnum_l*()	*newlocale*()	*vdprintf*()
120831 *isalpha_l*()	*openat*()	*wcpcpy*()
120832 *isblank_l*()	*open_memstream*()	*wcpncpy*()
120833 *iscntrl_l*()	*open_wmemstream*()	*wcscasecmp*()
120834 *isdigit_l*()	*psiginfo*()	*wcscasecmp_l*()
120835 *isgraph_l*()	*psignal*()	*wcscoll_l*()
120836 *islower_l*()	*pthread_mutexattr_getrobust*()	*wcsdup*()
120837 *isprint_l*()	*pthread_mutexattr_setrobust*()	*wcsncasecmp*()
120838 *ispunct_l*()	*pthread_mutex_consistent*()	*wcsncasecmp_l*()
120839 *isspace_l*()	*readlinkat*()	*wcsnlen*()
120840 *isupper_l*()	*renameat*()	*wcsnrtombs*()
120841 *iswalnum_l*()	*scandir*()	*wcsxfrm_l*()
120842 *iswalpha_l*()	*stpcpy*()	*wctrans_l*()
120843 *iswblank_l*()	*stpncpy*()	*wctype_l*()
120844 *iswcntrl_l*()	*strcasecmp_l*()	
120845 *iswctype_l*()	*strcoll_l*()	

120846 **Newly Mandated Functions in Issue 7**

120847 The functions that were previously part of an option group but are now mandatory in Issue 7 are
120848 as follows:

Newly Mandated Functions in Issue 7		
aio_cancel()	*pthread_atfork*()	*pthread_rwlock_tryrdlock*()
aio_error()	*pthread_attr_destroy*()	*pthread_rwlock_trywrlock*()
aio_fsync()	*pthread_attr_getdetachstate*()	*pthread_rwlock_unlock*()
aio_read()	*pthread_attr_getguardsize*()	*pthread_rwlock_wrlock*()
aio_return()	*pthread_attr_getschedparam*()	*pthread_rwlockattr_destroy*()
aio_suspend()	*pthread_attr_init*()	*pthread_rwlockattr_init*()
aio_write()	*pthread_attr_setdetachstate*()	*pthread_self*()
asctime_r()	*pthread_attr_setguardsize*()	*pthread_setcancelstate*()
catclose()	*pthread_attr_setschedparam*()	*pthread_setcanceltype*()
catgets()	*pthread_barrier_destroy*()	*pthread_setspecific*()
catopen()	*pthread_barrier_init*()	*pthread_spin_destroy*()
clock_getres()	*pthread_barrier_wait*()	*pthread_spin_init*()
clock_gettime()	*pthread_barrierattr_destroy*()	*pthread_spin_lock*()
clock_nanosleep()	*pthread_barrierattr_init*()	*pthread_spin_trylock*()
clock_settime()	*pthread_cancel*()	*pthread_spin_unlock*()
ctime_r()	*pthread_cleanup_pop*()	*pthread_testcancel*()
dlclose()	*pthread_cleanup_push*()	*putc_unlocked*()
dlerror()	*pthread_cond_broadcast*()	*putchar_unlocked*()
dlopen()	*pthread_cond_destroy*()	*pwrite*()
dlsym()	*pthread_cond_init*()	*rand_r*()
fchdir()	*pthread_cond_signal*()	*readdir_r*()

getgrgid_r()	*pthread_create*()	*sem_timedwait*()
getgrnam_r()	*pthread_detach*()	*sem_trywait*()
getlogin_r()	*pthread_equal*()	*sem_unlink*()
getpgid()	*pthread_exit*()	*sem_wait*()
getpwnam_r()	*pthread_getspecific*()	*sigqueue*()
getpwuid_r()	*pthread_join*()	*sigqueue*()
getsid()	*pthread_key_create*()	*sigtimedwait*()
getsubopt()	*pthread_key_delete*()	*sigwaitinfo*()
gmtime_r()	*pthread_mutex_destroy*()	*statvfs*()
iconv()	*pthread_mutex_init*()	*strcasecmp*()
iconv_close()	*pthread_mutex_lock*()	*strdup*()
iconv_open()	*pthread_mutex_timedlock*()	*strerror_r*()
lchown()	*pthread_mutex_trylock*()	*strfmon*()
lio_listio()	*pthread_mutex_unlock*()	*strncasecmp*()
localtime_r()	*pthread_mutexattr_destroy*()	*strtok_r*()
mkstemp()	*pthread_mutexattr_gettype*()	*tcgetsid*()
mmap()	*pthread_mutexattr_init*()	*timer_create*()
mprotect()	*pthread_mutexattr_settype*()	*timer_delete*()
munmap()	*pthread_once*()	*timer_getoverrun*()
nanosleep()	*pthread_rwlock_destroy*()	*timer_gettime*()
nl_langinfo()	*pthread_rwlock_init*()	*timer_settime*()
poll()	*pthread_rwlock_rdlock*()	*truncate*()
posix_trace_timedgetnext_event()	*pthread_rwlock_timedrdlock*()	*ttyname_r*()
pread()	*pthread_rwlock_timedwrlock*()	*waitid*()

120901 **Obsolescent Functions in Issue 7**

120902 The base functions moved to obsolescent status in Issue 7 (from the Issue 6 base document) are
120903 as follows:

120904

Obsolescent Base Functions in Issue 7	
120905 *asctime*( )	*gets*( )
120906 *asctime_r*( )	*rand_r*( )
120907 *ctime*( )	*tmpnam*( )
120908 *ctime_r*( )	*utime*( )

120909 The XSI functions moved to obsolescent status in Issue 7 (from the Issue 6 base document) are as
120910 follows:

120911

Obsolescent XSI Functions in Issue 7		
120912 *_longjmp*( )	*pthread_getconcurrency*( )	*sigset*( )
120913 *_setjmp*( )	*pthread_setconcurrency*( )	*siginterrupt*( )
120914 *_tolower*( )	*setitimer*( )	*tempnam*( )
120915 *_toupper*( )	*setpgrp*( )	*toascii*( )
120916 *ftw*( )	*sighold*( )	*ulimit*( )
120917 *getitimer*( )	*sigignore*( )	
120918 *gettimeofday*( )	*sigpause*( )	
120919 *isascii*( )	*sigrelse*( )	

120920 **Removed Functions and Symbols in Issue 7**

120921 The functions and symbols removed in Issue 7 (from the Issue 6 base document) are as follows:

120922

Removed Functions and Symbols in Issue 7		
120923 *bcmp*( )	*gethostbyaddr*( )	*rindex*( )
120924 *bcopy*( )	*gethostbyname*( )	*scalb*( )
120925 *bsd_signal*( )	*getwd*( )	*setcontext*( )
120926 *bzero*( )	*h_errno*	*swapcontext*( )
120927 *ecvt*( )	*index*( )	*ualarm*( )
120928 *fcvt*( )	*makecontext*( )	*usleep*( )
120929 *ftime*( )	*mktemp*( )	*vfork*( )
120930 *gcvt*( )	*pthread_attr_getstackaddr*( )	*wcswcs*( )
120931 *getcontext*( )	*pthread_attr_setstackaddr*( )	

120932 ### B.1.2 Relationship to Other Formal Standards

120933 There is no additional rationale provided for this section.

120934 ### B.1.3 Format of Entries

120935 Each system interface reference page has a common layout of sections describing the interface.
120936 This layout is similar to the manual page or ``man'' page format shipped with most UNIX
120937 systems, and each header has sections describing the SYNOPSIS, DESCRIPTION, RETURN
120938 VALUE, and ERRORS. These are the four sections that relate to conformance.

120939 Additional sections are informative, and add considerable information for the application
120940 developer. EXAMPLES sections provide example usage. APPLICATION USAGE sections

120941 provide additional caveats, issues, and recommendations to the developer. RATIONALE
120942 sections give additional information on the decisions made in defining the interface.

120943 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in
120944 the future, and often cautions the developer to architect the code to account for a change in this
120945 area. Note that a future directions statement should not be taken as a commitment to adopt a
120946 feature or interface in the future.

120947 The CHANGE HISTORY section describes when the interface was introduced, and how it has
120948 changed.

120949 Option labels and margin markings in the page can be useful in guiding the application
120950 developer.

120951 B.2 General Information

120952 B.2.1 Use and Implementation of Interfaces

120953 The information concerning the use of functions was adapted from a description in the ISO C
120954 standard. Here is an example of how an application program can protect itself from functions
120955 that may or may not be macros, rather than true functions:

120956 The *atoi*( ) function may be used in any of several ways:

120957 By use of its associated header (possibly generating a macro expansion):

```
120958 #include <stdlib.h>
120959 /* ... */
120960 i = atoi(str);
```

120961 By use of its associated header (assuredly generating a true function call):

```
120962 #include <stdlib.h>
120963 #undef atoi
120964 /* ... */
120965 i = atoi(str);
```

120966 or:

```
120967 #include <stdlib.h>
120968 /* ... */
120969 i = (atoi) (str);
```

120970 By explicit declaration:

```
120971 extern int atoi (const char *);
120972 /* ... */
120973 i = atoi(str);
```

120974 By implicit declaration:

```
120975 /* ... */
120976 i = atoi(str);
```

120977 (Assuming no function prototype is in scope. This is not allowed by the ISO C standard for
120978 functions with variable arguments; furthermore, parameter type conversion ``widening'' is

subject to different rules in this case.)

Note that the ISO C standard reserves names starting with '_' for the compiler. Therefore, the compiler could, for example, implement an intrinsic, built-in function *_asm_builtin_atoi*(), which it recognized and expanded into inline assembly code. Then, in **<stdlib.h>**, there could be the following:

```
#define atoi(X) _asm_builtin_atoi(X)
```

The user's ``normal'' call to *atoi*() would then be expanded inline, but the implementor would also be required to provide a callable function named *atoi*() for use when the application requires it; for example, if its address is to be stored in a function pointer variable.

Implementors should note that since applications can **#undef** a macro in order to ensure that the function is used, this means that it is not safe for implementations to use the names of any standard functions in macro values, since the application could use **#undef** to ensure that no macro exists and then use the same name for an identifier with local scope. For example, historically it was common for a *getchar*() macro to be defined in **<stdio.h>** as:

```
#define getchar() getc(stdin)
```

This definition does not conform, because an application is allowed to use the identifier *getc* with local scope, and the expansion of the *getchar*() macro would then pick up the local *getc*. The following is conforming code, but would not compile with the above definition of *getchar*():

```
#include <stdio.h>
#undef getc

int main(void)
{
    int getc;

    getc = getchar();

    return getc;
}
```

This does not only affect function-like macros. For example, the following definition does not conform because there could be a local *sysconf* variable in scope when SIGRTMIN is expanded:

```
#define SIGRTMIN ((int)sysconf(_SC_SIGRT_MIN))
```

Implementors can avoid the problem by using aliases for standard functions instead of the actual function, with names that conforming applications cannot use for local variables. For example:

```
#define SIGRTMIN ((int)__sysconf(_SC_SIGRT_MIN))
```

B.2.2 The Compilation Environment

B.2.2.1 POSIX.1 Symbols

This and the following section address the issue of ``name space pollution''. The ISO C standard requires that the name space beyond what it reserves not be altered except by explicit action of the application developer. This section defines the actions to add the POSIX.1 symbols for those headers where both the ISO C standard and POSIX.1 need to define symbols, and also where the

121018 XSI option extends the base standard.

121019 When headers are used to provide symbols, there is a potential for introducing symbols that the
121020 application developer cannot predict. Ideally, each header should only contain one set of
121021 symbols, but this is not practical for historical reasons. Thus, the concept of feature test macros is
121022 included. Two feature test macros are explicitly defined by POSIX.1-2017; it is expected that
121023 future versions may add to this.

121024 **Note:** Feature test macros allow an application to announce to the implementation its desire to have
121025 certain symbols and prototypes exposed. They should not be confused with the version test
121026 macros and constants for options in **<unistd.h>** which are the implementation's way of
121027 announcing functionality to the application.

121028 It is further intended that these feature test macros apply only to the headers specified by
121029 POSIX.1-2017. Implementations are expressly permitted to make visible symbols not specified
121030 by POSIX.1-2017, within both POSIX.1 and other headers, under the control of feature test
121031 macros that are not defined by POSIX.1-2017.

121032 **The _POSIX_C_SOURCE Feature Test Macro**

121033 The POSIX.1-1990 standard specified a macro called _POSIX_SOURCE. This has been
121034 superseded by _POSIX_C_SOURCE. This symbol will allow implementations to support various
121035 versions of this standard simultaneously. For instance, when _POSIX_C_SOURCE is defined as
121036 200809L, the system should make visible the same name space as permitted and required by the
121037 POSIX.1-2017 standard. A special case is the one where the implementation wishes to make
121038 available support for the 1990 version of the POSIX standard, in which instance when either
121039 _POSIX_SOURCE is defined or _POSIX_C_SOURCE is defined as 1, the system should make
121040 visible the same name space as permitted and required by the POSIX.1-1990 standard.

121041 It is expected that C bindings to future POSIX standards will define new values for
121042 _POSIX_C_SOURCE, with each new value reserving the name space for that new standard.

121043 **The _XOPEN_SOURCE Feature Test Macro**

121044 The feature test macro _XOPEN_SOURCE is provided as the announcement mechanism for the
121045 application that it requires functionality from the Single UNIX Specification. _XOPEN_SOURCE
121046 must be defined to the value 700 before the inclusion of any header to enable the functionality in
121047 the Single UNIX Specification Version 4. Its definition subsumes the use of _POSIX_C_SOURCE.

121048 An extract of code from a conforming application, that appears before any **#include** statements,
121049 is given below:

```
121050 #define _XOPEN_SOURCE 700 /* Single UNIX Specification, Version 4 */
121051 #include ...
```

121052 Note that the definition of _XOPEN_SOURCE with the value 700 makes the definition of
121053 _POSIX_C_SOURCE redundant and it can safely be omitted.

121054 *B.2.2.2 The Name Space*

121055 The reservation of identifiers is paraphrased from the ISO C standard. The text is included
121056 because it needs to be part of POSIX.1-2017, regardless of possible changes in future versions of
121057 the ISO C standard.

121058 These identifiers may be used by implementations, particularly for feature test macros.
121059 Implementations should not use feature test macro names that might be reasonably used by a
121060 standard.

Including headers more than once is a reasonably common practice, and it should be carried forward from the ISO C standard. More significantly, having definitions in more than one header is explicitly permitted. Where the potential declaration is ``benign'' (the same definition twice) the declaration can be repeated, if that is permitted by the compiler. (This is usually true of macros, for example.) In those situations where a repetition is not benign (for example, **typedef**s), conditional compilation must be used. The situation actually occurs both within the ISO C standard and within POSIX.1: **time_t** should be in **<sys/types.h>**, and the ISO C standard mandates that it be in **<time.h>**.

The area of name space pollution *versus* additions to structures is difficult because of the macro structure of C. The following discussion summarizes all the various problems with and objections to the issue.

Note the phrase ``user-defined macro''. Users are not permitted to define macro names (or any other name) beginning with `"_[A-Z_]"`. Thus, the conflict cannot occur for symbols reserved to the vendor's name space, and the permission to add fields automatically applies, without qualification, to those symbols.

1. Data structures (and unions) need to be defined in headers by implementations to meet certain requirements of POSIX.1 and the ISO C standard.

2. The structures defined by POSIX.1 are typically minimal, and any practical implementation would wish to add fields to these structures either to hold additional related information or for backwards-compatibility (or both). Future standards (and *de facto* standards) would also wish to add to these structures. Issues of field alignment make it impractical (at least in the general case) to simply omit fields when they are not defined by the particular standard involved.

   The **dirent** structure is an example of such a minimal structure (although one could argue about whether the other fields need visible names). The *st_rdev* field of most implementations' **stat** structure is a common example where extension is needed and where a conflict could occur.

3. Fields in structures are in an independent name space, so the addition of such fields presents no problem to the C language itself in that such names cannot interact with identically named user symbols because access is qualified by the specific structure name.

4. There is an exception to this: macro processing is done at a lexical level. Thus, symbols added to a structure might be recognized as user-provided macro names at the location where the structure is declared. This only can occur if the user-provided name is declared as a macro before the header declaring the structure is included. The user's use of the name after the declaration cannot interfere with the structure because the symbol is hidden and only accessible through access to the structure. Presumably, the user would not declare such a macro if there was an intention to use that field name.

5. Macros from the same or a related header might use the additional fields in the structure, and those field names might also collide with user macros. Although this is a less frequent occurrence, since macros are expanded at the point of use, no constraint on the order of use of names can apply.

6. An ``obvious'' solution of using names in the reserved name space and then redefining them as macros when they should be visible does not work because this has the effect of exporting the symbol into the general name space. For example, given a (hypothetical) system-provided header **<h.h>**, and two parts of a C program in **a.c** and **b.c**, in header **<h.h>**:

   ```
   struct foo {
       int __i;
   ```

```
}

#ifdef _FEATURE_TEST
#define i __i;
#endif
```

In file **a.c**:

```
#include h.h
extern int i;
...
```

In file **b.c**:

```
extern int i;
...
```

The symbol that the user thinks of as *i* in both files has an external name of *__i* in **a.c**; the same symbol *i* in **b.c** has an external name *i* (ignoring any hidden manipulations the compiler might perform on the names). This would cause a mysterious name resolution problem when **a.o** and **b.o** are linked.

Simply avoiding definition then causes alignment problems in the structure.

A structure of the form:

```
struct foo {
    union {
        int __i;
#ifdef _FEATURE_TEST
        int i;
#endif
    } __ii;
}
```

does not work because the name of the logical field *i* is *__ii.i*, and introduction of a macro to restore the logical name immediately reintroduces the problem discussed previously (although its manifestation might be more immediate because a syntax error would result if a recursive macro did not cause it to fail first).

7. A more workable solution would be to declare the structure:

```
struct foo {
#ifdef _FEATURE_TEST
    int i;
#else
    int __i;
#endif
}
```

However, if a macro (particularly one required by a standard) is to be defined that uses this field, two must be defined: one that uses *i*, the other that uses *__i*. If more than one additional field is used in a macro and they are conditional on distinct combinations of features, the complexity goes up as 2^n.

All this leaves a difficult situation: vendors must provide very complex headers to deal with what is conceptually simple and safe ‡ adding a field to a structure. It is the possibility of user-provided macros with the same name that makes this difficult.

Several alternatives were proposed that involved constraining the user's access to part of the

name space available to the user (as specified by the ISO C standard). In some cases, this was only until all the headers had been included. There were two proposals discussed that failed to achieve consensus:

1. Limiting it for the whole program.
2. Restricting the use of identifiers containing only uppercase letters until after all system headers had been included. It was also pointed out that because macros might wish to access fields of a structure (and macro expansion occurs totally at point of use) restricting names in this way would not protect the macro expansion, and thus the solution was inadequate.

It was finally decided that reservation of symbols would occur, but as constrained.

The current wording also allows the addition of fields to a structure, but requires that user macros of the same name not interfere. This allows vendors to do one of the following:

Not create the situation (do not extend the structures with user-accessible names or use the solution in (7) above)

Extend their compilers to allow some way of adding names to structures and macros safely

There are at least two ways that the compiler might be extended: add new preprocessor directives that turn off and on macro expansion for certain symbols (without changing the value of the macro) and a function or lexical operation that suppresses expansion of a word. The latter seems more flexible, particularly because it addresses the problem in macros as well as in declarations.

The following seems to be a possible implementation extension to the C language that will do this: any token that during macro expansion is found to be preceded by three `'#'` symbols shall not be further expanded in exactly the same way as described for macros that expand to their own name as in Section 3.8.3.4 of the ISO C standard. A vendor may also wish to implement this as an operation that is lexically a function, which might be implemented as:

```
#define __safe_name(x) ###x
```

Using a function notation would insulate vendors from changes in standards until such a functionality is standardized (if ever). Standardization of such a function would be valuable because it would then permit third parties to take advantage of it portably in software they may supply.

The symbols that are ``explicitly permitted, but not required by POSIX.1-2017'' include those classified below. (That is, the symbols classified below might, but are not required to, be present when _POSIX_C_SOURCE is defined to have the value 200809L.)

Symbols in **<limits.h>** and **<unistd.h>** that are defined to indicate support for options or limits that are constant at compile-time

Symbols in the name space reserved for the implementation by the ISO C standard

Symbols in a name space reserved for a particular type of extension (for example, type names ending with **_t** in **<sys/types.h>**)

Additional members of structures or unions whose names do not reduce the name space reserved for applications

Since both implementations and future versions of this standard and other POSIX standards may use symbols in the reserved spaces described in these tables, there is a potential for name space clashes. To avoid future name space clashes when adding symbols, implementations should not use the posix_, POSIX_, or _POSIX_ prefixes.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/2 is applied, deleting the entries POSIX_, _POSIX_, and posix_ from the column of allowed name space prefixes for use by an implementation in the first table. The presence of these prefixes was contradicting later text which states that: ``The prefixes posix_, POSIX_, and _POSIX are reserved for use by XCU Chapter 2 (on page 2345) and other POSIX standards. Implementations may add symbols to the headers shown in the following table, provided the identifiers ... do not use the reserved prefixes posix_, POSIX_, or _POSIX.''.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/3 is applied, correcting the reserved macro prefix from: ``PRI[a-z], SCN[a-z]'' to: ``PRI[Xa-z], SCN[Xa-z]'' in the second table. The change was needed since the ISO C standard allows implementations to define macros of the form PRI or SCN followed by any lowercase letter or `'X'` in **<inttypes.h>**. (The ISO/IEC 9899: 1999 standard, Subclause 7.26.4.)

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/4 is applied, adding a new section listing reserved names for the **<stdint.h>** header. This change is for alignment with the ISO C standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/2 is applied, making it clear that implementations are permitted to have symbols with the prefix _POSIX_ visible in any header.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/3 is applied, updating the table of allowed macro prefixes to include the prefix FP_[A-Z] for **<math.h>**. This text is added for consistency with the **<math.h>** reference page in the Base Definitions volume of POSIX.1-2017 which permits additional implementation-defined floating-point classifications.

Austin Group Interpretation 1003.1-2001 #048 is applied, reserving SEEK_ in the name space.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0001 [801], XSH/TC2-2008/0002 [780], XSH/TC2-2008/0003 [790], XSH/TC2-2008/0004 [780], XSH/TC2-2008/0005 [790], XSH/TC2-2008/0006 [782], XSH/TC2-2008/0007 [790], and XSH/TC2-2008/0008 [790] are applied.

B.2.3 Error Numbers

It was the consensus of the standard developers that to allow the conformance document to state that an error occurs and under what conditions, but to disallow a statement that it never occurs, does not make sense. It could be implied by the current wording that this is allowed, but to reduce the possibility of future interpretation requests, it is better to make an explicit statement.

The ISO C standard requires that *errno* be an assignable lvalue. Originally, the definition in POSIX.1 was stricter than that in the ISO C standard, **extern int** *errno*, in order to support historical usage. In a multi-threaded environment, implementing *errno* as a global variable results in non-deterministic results when accessed. It is required, however, that *errno* work as a per-thread error reporting mechanism. In order to do this, a separate *errno* value has to be maintained for each thread. The following section discusses the various alternative solutions that were considered.

In order to avoid this problem altogether for new functions, these functions avoid using *errno* and, instead, return the error number directly as the function return value; a return value of zero indicates that no error was detected.

For any function that can return errors, the function return value is not used for any purpose other than for reporting errors. Even when the output of the function is scalar, it is passed through a function argument. While it might have been possible to allow some scalar outputs to be coded as negative function return values and mixed in with positive error status returns, this was rejected—using the return value for a mixed purpose was judged to be of limited use and error prone.

Checking the value of *errno* alone is not sufficient to determine the existence or type of an error, since it is not required that a successful function call clear *errno*. The variable *errno* should only be examined when the return value of a function indicates that the value of *errno* is meaningful. In that case, the function is required to set the variable to something other than zero.

The variable *errno* is never set to zero by any function call; to do so would contradict the ISO C standard.

POSIX.1 requires (in the ERRORS sections of function descriptions) certain error values to be set in certain conditions because many existing applications depend on them. Some error numbers, such as [EFAULT], are entirely implementation-defined and are noted as such in their description in the ERRORS section. This section otherwise allows wide latitude to the implementation in handling error reporting.

Some of the ERRORS sections in POSIX.1-2017 have two subsections. The first:

> ``The function shall fail if:''

could be called the ``mandatory'' section.

The second:

> ``The function may fail if:''

could be informally known as the ``optional'' section.

Attempting to infer the quality of an implementation based on whether it detects optional error conditions is not useful.

Following each one-word symbolic name for an error, there is a description of the error. The rationale for some of the symbolic names follows:

[ECANCELED] This spelling was chosen as being more common.

[EFAULT] Most historical implementations do not catch an error and set *errno* when an invalid address is given to the functions *wait*(), *time*(), or *times*(). Some implementations cannot reliably detect an invalid address. And most systems that detect invalid addresses will do so only for a system call, not for a library routine.

[EFTYPE] This error code was proposed in earlier proposals as ``Inappropriate operation for file type'', meaning that the operation requested is not appropriate for the file specified in the function call. This code was proposed, although the same idea was covered by [ENOTTY], because the connotations of the name would be misleading. It was pointed out that the *fcntl*() function uses the error code [EINVAL] for this notion, and hence all instances of [EFTYPE] were changed to this code.

[EINTR] POSIX.1 prohibits conforming implementations from restarting interrupted system calls of conforming applications unless the SA_RESTART flag is in effect for the signal. However, it does not require that [EINTR] be returned when another legitimate value may be substituted; for example, a partial transfer count when *read*() or *write*() are interrupted. This is only given when the signal-catching function returns normally as opposed to returns by mechanisms like *longjmp*() or *siglongjmp*().

[ELOOP] In specifying conditions under which implementations would generate this error, the following goals were considered:

To ensure that actual loops are detected, including loops that result from symbolic links across distributed file systems.

To ensure that during pathname resolution an application can rely on the ability to follow at least {SYMLOOP_MAX} symbolic links in the absence of a loop.

To allow implementations to provide the capability of traversing more than {SYMLOOP_MAX} symbolic links in the absence of a loop.

To allow implementations to detect loops and generate the error prior to encountering {SYMLOOP_MAX} symbolic links.

[ENAMETOOLONG]

When a symbolic link is encountered during pathname resolution, the contents of that symbolic link are used to create a new pathname. The standard developers intended to allow, but not require, that implementations enforce the restriction of {PATH_MAX} on the result of this pathname substitution.

Implementations are allowed, but not required, to treat a pathname longer than {PATH_MAX} passed into the system as an error. Implementations are required to return a pathname (even if it is longer than {PATH_MAX}) when the user supplies a buffer with an interface that specifies the buffer size, as long as the user-supplied buffer is large enough to hold the entire pathname (see XSH *getcwd*( ) for an example of this type of interface). Implementations are required to treat a request to pass a pathname longer than {PATH_MAX} from the system to a user-supplied buffer of an unspecified size (usually assumed to be of size {PATH_MAX}) as an error (see XSH *realpath*( ) for an example of this type of interface).

[ENOMEM] The term ``main memory'' is not used in POSIX.1 because it is implementation-defined.

[ENOTSUP] This error code is to be used when an implementation chooses to implement the required functionality of POSIX.1-2017 but does not support optional facilities defined by POSIX.1-2017. In some earlier versions of this standard, the difference between [ENOTSUP] and [ENOSYS] was that [ENOSYS] indicated that the function was not supported at all. This is no longer the case as [ENOSYS] can also be used to indicate non-support of optional functionality for a function that has some required functionality. (See XSH *encrypt*( ).)

[ENOTTY] The symbolic name for this error is derived from a time when device control was done by *ioctl*( ) and that operation was only permitted on a terminal interface. The term ``TTY'' is derived from ``teletypewriter'', the devices to which this error originally applied.

[EOVERFLOW] Most of the uses of this error code are related to large file support. Typically, these cases occur on systems which support multiple programming environments with different sizes for **off_t**, but they may also occur in connection with remote file systems.

In addition, when different programming environments have different widths for types such as **int** and **uid_t**, several functions may encounter a condition where a value in a particular environment is too wide to be represented. In that case, this error should be raised. For example, suppose the currently running process has 64-bit **int**, and file descriptor 9 223 372 036 854 775 807 is

open and does not have the close-on-*exec* flag set. If the process then uses *execl*() to *exec* a file compiled in a programming environment with 32-bit **int**, the call to *execl*() can fail with *errno* set to [EOVERFLOW]. A similar failure can occur with *execl*() if any of the user IDs or any of the group IDs to be assigned to the new process image are out of range for the executed file's programming environment.

Note, however, that this condition cannot occur for functions that are explicitly described as always being successful, such as *getpid*().

[EPIPE] This condition normally generates the signal SIGPIPE; the error is returned if the generation of the signal is suppressed or the signal does not terminate the process.

[EROFS] In historical implementations, attempting to *unlink*() or *rmdir*() a mount point would generate an [EBUSY] error. An implementation could be envisioned where such an operation could be performed without error. In this case, if *either* the directory entry or the actual data structures reside on a read-only file system, [EROFS] is the appropriate error to generate. (For example, changing the link count of a file on a read-only file system could not be done, as is required by *unlink*(), and thus an error should be reported.)

Three error numbers, [EDOM], [EILSEQ], and [ERANGE], were added to this section primarily for consistency with the ISO C standard.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0009 [496] and XSH/TC2-2008/0010 [681] are applied.

Alternative Solutions for Per-Thread errno

The usual implementation of *errno* as a single global variable does not work in a multi-threaded environment. In such an environment, a thread may make a POSIX.1 call and get a −1 error return, but before that thread can check the value of *errno*, another thread might have made a second POSIX.1 call that also set *errno*. This behavior is unacceptable in robust programs. There were a number of alternatives that were considered for handling the *errno* problem:

Implement *errno* as a per-thread integer variable.

Implement *errno* as a service that can access the per-thread error number.

Change all POSIX.1 calls to accept an extra status argument and avoid setting *errno*.

Change all POSIX.1 calls to raise a language exception.

The first option offers the highest level of compatibility with existing practice but requires special support in the linker, compiler, and/or virtual memory system to support the new concept of thread private variables. When compared with current practice, the third and fourth options are much cleaner, more efficient, and encourage a more robust programming style, but they require new versions of all of the POSIX.1 functions that might detect an error. The second option offers compatibility with existing code that uses the **<errno.h>** header to define the symbol *errno*. In this option, *errno* may be a macro defined:

```
#define errno  (*__errno())
extern int      *__errno();
```

This option may be implemented as a per-thread variable whereby an *errno* field is allocated in the user space object representing a thread, and whereby the function *__errno*() makes a system call to determine the location of its user space object and returns the address of the *errno* field of that object. Another implementation, one that avoids calling the kernel, involves allocating

stacks in chunks. The stack allocator keeps a side table indexed by chunk number containing a pointer to the thread object that uses that chunk. The *__errno*() function then looks at the stack pointer, determines the chunk number, and uses that as an index into the chunk table to find its thread object and thus its private value of *errno*. On most architectures, this can be done in four to five instructions. Some compilers may wish to implement *__errno*() inline to improve performance.

Disallowing Return of the [EINTR] Error Code

Many blocking interfaces defined by POSIX.1-2017 may return [EINTR] if interrupted during their execution by a signal handler. Blocking interfaces introduced under the threads functionality do not have this property. Instead, they require that the interface appear to be atomic with respect to interruption. In particular, clients of blocking interfaces need not handle any possible [EINTR] return as a special case since it will never occur. If it is necessary to restart operations or complete incomplete operations following the execution of a signal handler, this is handled by the implementation, rather than by the application.

Requiring applications to handle [EINTR] errors on blocking interfaces has been shown to be a frequent source of often unreproducible bugs, and it adds no compelling value to the available functionality. Thus, blocking interfaces introduced for use by multi-threaded programs do not use this paradigm. In particular, in none of the functions *flockfile*(), *pthread_cond_timedwait*(), *pthread_cond_wait*(), *pthread_join*(), *pthread_mutex_lock*(), and *sigwait*() did providing [EINTR] returns add value, or even particularly make sense. Thus, these functions do not provide for an [EINTR] return, even when interrupted by a signal handler. The same arguments can be applied to *sem_wait*(), *sem_trywait*(), *sigwaitinfo*(), and *sigtimedwait*(), but implementations are permitted to return [EINTR] error codes for these functions for compatibility with earlier versions of this standard. Applications cannot rely on calls to these functions returning [EINTR] error codes when signals are delivered to the calling thread, but they should allow for the possibility.

Austin Group Interpretation 1003.1-2001 #050 is applied, allowing [ENOTSUP] and [EOPNOTSUPP] to be the same values.

B.2.3.1 Additional Error Numbers

The ISO C standard defines the name space for implementations to add additional error numbers.

B.2.4 Signal Concepts

Historical implementations of signals, using the *signal*() function, have shortcomings that make them unreliable for many application uses. Because of this, a new signal mechanism, based very closely on the one of 4.2 BSD and 4.3 BSD, was added to POSIX.1.

Signal Names

The restriction on the actual type used for **sigset_t** is intended to guarantee that these objects can always be assigned, have their address taken, and be passed as parameters by value. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of some integer type.

The signals described in POSIX.1-2017 must have unique values so that they may be named as parameters of **case** statements in the body of a C-language **switch** clause. However,

implementation-defined signals may have values that overlap with each other or with signals specified in POSIX.1-2017. An example of this is SIGABRT, which traditionally overlaps some other signal, such as SIGIOT.

SIGKILL, SIGTERM, SIGUSR1, and SIGUSR2 are ordinarily generated only through the explicit use of the *kill*() function, although some implementations generate SIGKILL under extraordinary circumstances. SIGTERM is traditionally the default signal sent by the *kill* command.

The signals SIGBUS, SIGEMT, SIGIOT, SIGTRAP, and SIGSYS were omitted from POSIX.1 because their behavior is implementation-defined and could not be adequately categorized. Conforming implementations may deliver these signals, but must document the circumstances under which they are delivered and note any restrictions concerning their delivery. The signals SIGFPE, SIGILL, and SIGSEGV are similar in that they also generally result only from programming errors. They were included in POSIX.1 because they do indicate three relatively well-categorized conditions. They are all defined by the ISO C standard and thus would have to be defined by any system with an ISO C standard binding, even if not explicitly included in POSIX.1.

There is very little that a Conforming POSIX.1 Application can do by catching, ignoring, or masking any of the signals SIGILL, SIGTRAP, SIGIOT, SIGEMT, SIGBUS, SIGSEGV, SIGSYS, or SIGFPE. They will generally be generated by the system only in cases of programming errors. While it may be desirable for some robust code (for example, a library routine) to be able to detect and recover from programming errors in other code, these signals are not nearly sufficient for that purpose. One portable use that does exist for these signals is that a command interpreter can recognize them as the cause of termination of a process (with *wait*()) and print an appropriate message. The mnemonic tags for these signals are derived from their PDP-11 origin.

The signals SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU, and SIGCONT are provided for job control and are unchanged from 4.2 BSD. The signal SIGCHLD is also typically used by job control shells to detect children that have terminated or, as in 4.2 BSD, stopped.

Some implementations, including System V, have a signal named SIGCLD, which is similar to SIGCHLD in 4.2 BSD. POSIX.1 permits implementations to have a single signal with both names. POSIX.1 carefully specifies ways in which conforming applications can avoid the semantic differences between the two different implementations. The name SIGCHLD was chosen for POSIX.1 because most current application usages of it can remain unchanged in conforming applications. SIGCLD in System V has more cases of semantics that POSIX.1 does not specify, and thus applications using it are more likely to require changes in addition to the name change.

The signals SIGUSR1 and SIGUSR2 are commonly used by applications for notification of exceptional behavior and are described as ``reserved as application-defined'' so that such use is not prohibited. Implementations should not generate SIGUSR1 or SIGUSR2, except when explicitly requested by *kill*(). It is recommended that libraries not use these two signals, as such use in libraries could interfere with their use by applications calling the libraries. If such use is unavoidable, it should be documented. It is prudent for non-portable libraries to use non-standard signals to avoid conflicts with use of standard signals by portable libraries.

There is no portable way for an application to catch or ignore non-standard signals. Some implementations define the range of signal numbers, so applications can install signal-catching functions for all of them. Unfortunately, implementation-defined signals often cause problems when caught or ignored by applications that do not understand the reason for the signal. While the desire exists for an application to be more robust by handling all possible signals (even those only generated by *kill*()), no existing mechanism was found to be sufficiently portable to include in POSIX.1. The value of such a mechanism, if included, would be diminished given that

SIGKILL would still not be catchable.

A number of new signal numbers are reserved for applications because the two user signals defined by POSIX.1 are insufficient for many realtime applications. A range of signal numbers is specified, rather than an enumeration of additional reserved signal names, because different applications and application profiles will require a different number of application signals. It is not desirable to burden all application domains and therefore all implementations with the maximum number of signals required by all possible applications. Note that in this context, signal numbers are essentially different signal priorities.

The relatively small number of required additional signals, {_POSIX_RTSIG_MAX}, was chosen so as not to require an unreasonably large signal mask/set. While this number of signals defined in POSIX.1 will fit in a single 32-bit word signal mask, it is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the ``null signal''). Support of {_POSIX_RTSIG_MAX} additional signals may push some implementation over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64-signal line.

B.2.4.1 *Signal Generation and Delivery*

The terms defined in this section are not used consistently in documentation of historical systems. Each signal can be considered to have a lifetime beginning with generation and ending with delivery or acceptance. The POSIX.1 definition of ``delivery'' does not exclude ignored signals; this is considered a more consistent definition. This revised text in several parts of POSIX.1-2017 clarifies the distinct semantics of asynchronous signal delivery and synchronous signal acceptance. The previous wording attempted to categorize both under the term ``delivery'', which led to conflicts over whether the effects of asynchronous signal delivery applied to synchronous signal acceptance.

Signals generated for a process are delivered to only one thread. Thus, if more than one thread is eligible to receive a signal, one has to be chosen. The choice of threads is left entirely up to the implementation both to allow the widest possible range of conforming implementations and to give implementations the freedom to deliver the signal to the ``easiest possible'' thread should there be differences in ease of delivery between different threads.

Note that should multiple delivery among cooperating threads be required by an application, this can be trivially constructed out of the provided single-delivery semantics. The construction of a *sigwait_multiple*() function that accomplishes this goal is presented with the rationale for *sigwaitinfo*().

Implementations should deliver unblocked signals as soon after they are generated as possible. However, it is difficult for POSIX.1 to make specific requirements about this, beyond those in *kill*() and *sigprocmask*(). Even on systems with prompt delivery, scheduling of higher priority processes is always likely to cause delays.

In general, the interval between the generation and delivery of unblocked signals cannot be detected by an application. Thus, references to pending signals generally apply to blocked, pending signals. An implementation registers a signal as pending on the process when no thread has the signal unblocked and there are no threads blocked in a *sigwait*() function for that signal. Thereafter, the implementation delivers the signal to the first thread that unblocks the signal or calls a *sigwait*() function on a signal set containing this signal rather than choosing the recipient thread at the time the signal is sent.

In the 4.3 BSD system, signals that are blocked and set to SIG_IGN are discarded immediately upon generation. For a signal that is ignored as its default action, if the action is SIG_DFL and

the signal is blocked, a generated signal remains pending. In the 4.1 BSD system and in System V Release 3 (two other implementations that support a somewhat similar signal mechanism), all ignored blocked signals remain pending if generated. Because it is not normally useful for an application to simultaneously ignore and block the same signal, it was unnecessary for POSIX.1 to specify behavior that would invalidate any of the historical implementations.

There is one case in some historical implementations where an unblocked, pending signal does not remain pending until it is delivered. In the System V implementation of *signal*(), pending signals are discarded when the action is set to SIG_DFL or a signal-catching routine (as well as to SIG_IGN). Except in the case of setting SIGCHLD to SIG_DFL, implementations that do this do not conform completely to POSIX.1. Some earlier proposals for POSIX.1 explicitly stated this, but these statements were redundant due to the requirement that functions defined by POSIX.1 not change attributes of processes defined by POSIX.1 except as explicitly stated.

POSIX.1 specifically states that the order in which multiple, simultaneously pending signals are delivered is unspecified. This order has not been explicitly specified in historical implementations, but has remained quite consistent and been known to those familiar with the implementations. Thus, there have been cases where applications (usually system utilities) have been written with explicit or implicit dependencies on this order. Implementors and others porting existing applications may need to be aware of such dependencies.

When there are multiple pending signals that are not blocked, implementations should arrange for the delivery of all signals at once, if possible. Some implementations stack calls to all pending signal-catching routines, making it appear that each signal-catcher was interrupted by the next signal. In this case, the implementation should ensure that this stacking of signals does not violate the semantics of the signal masks established by *sigaction*(). Other implementations process at most one signal when the operating system is entered, with remaining signals saved for later delivery. Although this practice is widespread, this behavior is neither standardized nor endorsed. In either case, implementations should attempt to deliver signals associated with the current state of the process (for example, SIGFPE) before other signals, if possible.

In 4.2 BSD and 4.3 BSD, it is not permissible to ignore or explicitly block SIGCONT, because if blocking or ignoring this signal prevented it from continuing a stopped process, such a process could never be continued (only killed by SIGKILL). However, 4.2 BSD and 4.3 BSD do block SIGCONT during execution of its signal-catching function when it is caught, creating exactly this problem. A proposal was considered to disallow catching SIGCONT in addition to ignoring and blocking it, but this limitation led to objections. The consensus was to require that SIGCONT always continue a stopped process when generated. This removed the need to disallow ignoring or explicit blocking of the signal; note that SIG_IGN and SIG_DFL are equivalent for SIGCONT.

B.2.4.2 *Realtime Signal Generation and Delivery*

The realtime signals functionality is required in this version of the standard for the following reasons:

The **sigevent** structure is used by other POSIX.1 functions that result in asynchronous event notifications to specify the notification mechanism to use and other information needed by the notification mechanism. POSIX.1-2017 defines only three symbolic values for the notification mechanism:

‡ SIGEV_NONE is used to indicate that no notification is required when the event occurs. This is useful for applications that use asynchronous I/O with polling for completion.

- SIGEV_SIGNAL indicates that a signal is generated when the event occurs.
- SIGEV_THREAD provides for ``callback functions'' for asynchronous notifications done by a function call within the context of a new thread. This provides a multi-threaded process with a more natural means of notification than signals.

The primary difficulty with previous notification approaches has been to specify the environment of the notification routine.

- One approach is to limit the notification routine to call only functions permitted in a signal handler. While the list of permissible functions is clearly stated, this is overly restrictive.
- A second approach is to define a new list of functions or classes of functions that are explicitly permitted or not permitted. This would give a programmer more lists to deal with, which would be awkward.
- The third approach is to define completely the environment for execution of the notification function. A clear definition of an execution environment for notification is provided by executing the notification function in the environment of a newly created thread.

Implementations may support additional notification mechanisms by defining new values for *sigev_notify*.

For a notification type of SIGEV_SIGNAL, the other members of the **sigevent** structure defined by POSIX.1-2017 specify the realtime signal—that is, the signal number and application-defined value that differentiates between occurrences of signals with the same number that will be generated when the event occurs. The structure is defined in **<signal.h>**, even though the structure is not directly used by any of the signal functions, because it is part of the signals interface used by the POSIX.1b ``client functions''. When the client functions include **<signal.h>** to define the signal names, the **sigevent** structure will also be defined.

An application-defined value passed to the signal handler is used to differentiate between different ``events'' instead of requiring that the application use different signal numbers for several reasons:

- Realtime applications potentially handle a very large number of different events. Requiring that implementations support a correspondingly large number of distinct signal numbers will adversely impact the performance of signal delivery because the signal masks to be manipulated on entry and exit to the handlers will become large.
- Event notifications are prioritized by signal number (the rationale for this is explained in the following paragraphs) and the use of different signal numbers to differentiate between the different event notifications overloads the signal number more than has already been done. It also requires that the application developer make arbitrary assignments of priority to events that are logically of equal priority.

A union is defined for the application-defined value so that either an integer constant or a pointer can be portably passed to the signal-catching function. On some architectures a pointer cannot be cast to an **int** and *vice versa*.

Use of a structure here with an explicit notification type discriminant rather than explicit parameters to realtime functions, or embedded in other realtime structures, provides for future extensions to POSIX.1-2017. Additional, perhaps more efficient, notification mechanisms can be supported for existing realtime function interfaces, such as timers and asynchronous I/O, by extending the **sigevent** structure appropriately. The existing realtime function interfaces will not have to be modified to use any such new notification

mechanism. The revised text concerning the SIGEV_SIGNAL value makes consistent the semantics of the members of the **sigevent** structure, particularly in the definitions of *lio_listio*() and *aio_fsync*(). For uniformity, other revisions cause this specification to be referred to rather than inaccurately duplicated in the descriptions of functions and structures using the **sigevent** structure. The revised wording does not relax the requirement that the signal number be in the range SIGRTMIN to SIGRTMAX to guarantee queuing and passing of the application value, since that requirement is still implied by the signal names.

POSIX.1-2017 is intentionally vague on whether ``non-realtime'' signal-generating mechanisms can result in a **siginfo_t** being supplied to the handler on delivery. In one existing implementation, a **siginfo_t** is posted on signal generation, even though the implementation does not support queuing of multiple occurrences of a signal. It is not the intent of POSIX.1-2017 to preclude this, independent of the mandate to define signals that do support queuing. Any interpretation that appears to preclude this is a mistake in the reading or writing of the standard.

Signals handled by realtime signal handlers might be generated by functions or conditions that do not allow the specification of an application-defined value and do not queue. POSIX.1-2017 specifies the *si_code* member of the **siginfo_t** structure used in existing practice and defines additional codes so that applications can detect whether an application-defined value is present or not. The code SI_USER for *kill*()-generated signals is adopted from existing practice.

The *sigaction*() *sa_flags* value SA_SIGINFO tells the implementation that the signal-catching function expects two additional arguments. When the flag is not set, a single argument, the signal number, is passed as specified by POSIX.1-2017. Although POSIX.1-2017 does not explicitly allow the *info* argument to the handler function to be NULL, this is existing practice. This provides for compatibility with programs whose signal-catching functions are not prepared to accept the additional arguments. POSIX.1-2017 is explicitly unspecified as to whether signals actually queue when SA_SIGINFO is not set for a signal, as there appear to be no benefits to applications in specifying one behavior or another. One existing implementation queues a **siginfo_t** on each signal generation, unless the signal is already pending, in which case the implementation discards the new **siginfo_t**; that is, the queue length is never greater than one. This implementation only examines SA_SIGINFO on signal delivery, discarding the queued **siginfo_t** if its delivery was not requested.

The third argument to the signal-catching function, *context*, is left undefined by POSIX.1-2017, but is specified in the interface because it matches existing practice for the SA_SIGINFO flag. It was considered undesirable to require a separate implementation for SA_SIGINFO for POSIX conformance on implementations that already support the two additional parameters.

The requirement to deliver lower numbered signals in the range SIGRTMIN to SIGRTMAX first, when multiple unblocked signals are pending, results from several considerations:

‡ A method is required to prioritize event notifications. The signal number was chosen instead of, for instance, associating a separate priority with each request, because an implementation has to check pending signals at various points and select one for delivery when more than one is pending. Specifying a selection order is the minimal additional semantic that will achieve prioritized delivery. If a separate priority were to be associated with queued signals, it would be necessary for an implementation to search all non-empty, non-blocked signal queues and select from among them the pending signal with the highest priority. This would significantly increase the cost of and decrease the determinism of signal delivery.

‡ Given the specified selection of the lowest numeric unblocked pending signal, preemptive priority signal delivery can be achieved using signal numbers and signal masks by ensuring that the *sa_mask* for each signal number blocks all signals with a higher numeric value.

For realtime applications that want to use only the newly defined realtime signal numbers without interference from the standard signals, this can be achieved by blocking all of the standard signals in the thread signal mask and in the *sa_mask* installed by the signal action for the realtime signal handlers.

POSIX.1-2017 explicitly leaves unspecified the ordering of signals outside of the range of realtime signals and the ordering of signals within this range with respect to those outside the range. It was believed that this would unduly constrain implementations or standards in the future definition of new signals.

B.2.4.3 Signal Actions

Early proposals mentioned SIGCONT as a second exception to the rule that signals are not delivered to stopped processes until continued. Because POSIX.1-2017 now specifies that SIGCONT causes the stopped process to continue when it is generated, delivery of SIGCONT is not prevented because a process is stopped, even without an explicit exception to this rule.

Ignoring a signal by setting the action to SIG_IGN (or SIG_DFL for signals whose default action is to ignore) is not the same as installing a signal-catching function that simply returns. Invoking such a function will interrupt certain system functions that block processes (for example, *wait*( ), *sigsuspend*( ), *pause*( ), *read*( ), *write*( )) while ignoring a signal has no such effect on the process.

Historical implementations discard pending signals when the action is set to SIG_IGN. However, they do not always do the same when the action is set to SIG_DFL and the default action is to ignore the signal. POSIX.1-2017 requires this for the sake of consistency and also for completeness, since the only signal this applies to is SIGCHLD, and POSIX.1-2017 disallows setting its action to SIG_IGN.

Some implementations (System V, for example) assign different semantics for SIGCLD depending on whether the action is set to SIG_IGN or SIG_DFL. Since POSIX.1 requires that the default action for SIGCHLD be to ignore the signal, applications should always set the action to SIG_DFL in order to avoid SIGCHLD.

Whether or not an implementation allows SIG_IGN as a SIGCHLD disposition to be inherited across a call to one of the *exec* family of functions or *posix_spawn*( ) is explicitly left as unspecified. This change was made as a result of IEEE PASC Interpretation 1003.1 #132, and permits the implementation to decide between the following alternatives:

Unconditionally leave SIGCHLD set to SIG_IGN, in which case the implementation would not allow applications that assume inheritance of SIG_DFL to conform to POSIX.1-2017 without change. The implementation would, however, retain an ability to control applications that create child processes but never call on the *wait* family of functions, potentially filling up the process table.

Unconditionally reset SIGCHLD to SIG_DFL, in which case the implementation would allow applications that assume inheritance of SIG_DFL to conform. The implementation would, however, lose an ability to control applications that spawn child processes but never reap them.

Provide some mechanism, not specified in POSIX.1-2017, to control inherited SIGCHLD dispositions.

Some implementations (System V, for example) will deliver a SIGCLD signal immediately when

a process establishes a signal-catching function for SIGCLD when that process has a child that has already terminated. Other implementations, such as 4.3 BSD, do not generate a new SIGCHLD signal in this way. In general, a process should not attempt to alter the signal action for the SIGCHLD signal while it has any outstanding children. However, it is not always possible for a process to avoid this; for example, shells sometimes start up processes in pipelines with other processes from the pipeline as children. Processes that cannot ensure that they have no children when altering the signal action for SIGCHLD thus need to be prepared for, but not depend on, generation of an immediate SIGCHLD signal.

The default action of the stop signals (SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU) is to stop a process that is executing. If a stop signal is delivered to a process that is already stopped, it has no effect. In fact, if a stop signal is generated for a stopped process whose signal mask blocks the signal, the signal will never be delivered to the process since the process must receive a SIGCONT, which discards all pending stop signals, in order to continue executing.

The SIGCONT signal continues a stopped process even if SIGCONT is blocked (or ignored). However, if a signal-catching routine has been established for SIGCONT, it will not be entered until SIGCONT is unblocked.

If a process in an orphaned process group stops, it is no longer under the control of a job control shell and hence would not normally ever be continued. Because of this, orphaned processes that receive terminal-related stop signals (SIGTSTP, SIGTTIN, SIGTTOU, but not SIGSTOP) must not be allowed to stop. The goal is to prevent stopped processes from languishing forever. (As SIGSTOP is sent only via *kill*(), it is assumed that the process or user sending a SIGSTOP can send a SIGCONT when desired.) Instead, the system must discard the stop signal. As an extension, it may also deliver another signal in its place. 4.3 BSD sends a SIGKILL, which is overly effective because SIGKILL is not catchable. Another possible choice is SIGHUP. 4.3 BSD also does this for orphaned processes (processes whose parent has terminated) rather than for members of orphaned process groups; this is less desirable because job control shells manage process groups. POSIX.1 also prevents SIGTTIN and SIGTTOU signals from being generated for processes in orphaned process groups as a direct result of activity on a terminal, preventing infinite loops when *read*() and *write*() calls generate signals that are discarded; see Section A.11.1.4 (on page 3551). A similar restriction on the generation of SIGTSTP was considered, but that would be unnecessary and more difficult to implement due to its asynchronous nature.

Although POSIX.1 requires that signal-catching functions be called with only one argument, there is nothing to prevent conforming implementations from extending POSIX.1 to pass additional arguments, as long as Strictly Conforming POSIX.1 Applications continue to compile and execute correctly. Most historical implementations do, in fact, pass additional, signal-specific arguments to certain signal-catching routines.

There was a proposal to change the declared type of the signal handler to:

```
void func (int sig, ...);
```

The usage of ellipses ("...") is ISO C standard syntax to indicate a variable number of arguments. Its use was intended to allow the implementation to pass additional information to the signal handler in a standard manner.

Unfortunately, this construct would require all signal handlers to be defined with this syntax because the ISO C standard allows implementations to use a different parameter passing mechanism for variable parameter lists than for non-variable parameter lists. Thus, all existing signal handlers in all existing applications would have to be changed to use the variable syntax in order to be standard and portable. This is in conflict with the goal of Minimal Changes to Existing Application Code.

When terminating a process from a signal-catching function, processes should be aware of any

interpretation that their parent may make of the status returned by *wait*(), *waitid*(), or *waitpid*(). In particular, a signal-catching function should not call *exit*(0) or *_exit*(0) unless it wants to indicate successful termination. A non-zero argument to *exit*() or *_exit*() can be used to indicate unsuccessful termination. Alternatively, the process can use *kill*() to send itself a fatal signal (first ensuring that the signal is set to the default action and not blocked). See also the RATIONALE section of the *_exit*() function.

The behavior of *unsafe* functions, as defined by this section, is undefined when they are called from (or after a *longjmp*() or *siglongjmp*() out of) signal-catching functions in certain circumstances. The behavior of async-signal-safe functions, as defined by this section, is as specified by POSIX.1, regardless of invocation from a signal-catching function. This is the only intended meaning of the statement that async-signal-safe functions may be used in signal-catching functions without restriction. Applications must still consider all effects of such functions on such things as data structures, files, and process state. In particular, application developers need to consider the restrictions on interactions when interrupting *sleep*() (see *sleep*()) and interactions among multiple handles for a file description. The fact that any specific function is listed as async-signal-safe does not necessarily mean that invocation of that function from a signal-catching function is recommended.

In order to prevent errors arising from interrupting non-async-signal-safe function calls, applications should protect calls to these functions either by blocking the appropriate signals or through the use of some programmatic semaphore. POSIX.1 does not address the more general problem of synchronizing access to shared data structures. Note in particular that even the ``safe'' functions may modify the global variable *errno*; the signal-catching function may want to save and restore its value. The same principles apply to the async-signal-safety of application routines and asynchronous data access.

Note that although *longjmp*() and *siglongjmp*() are in the list of async-signal-safe functions, there are restrictions on subsequent behavior after the function is called from a signal-catching function. This is because the code executing after *longjmp*() or *siglongjmp*() can call any unsafe functions with the same danger as calling those unsafe functions directly from the signal handler. Applications that use *longjmp*() or *siglongjmp*() out of signal handlers require rigorous protection in order to be portable. Many of the other functions that are excluded from the list are traditionally implemented using either the C language *malloc*() or *free*() functions or the ISO C standard I/O library, both of which traditionally use data structures in a non-async-signal-safe manner. Because any combination of different functions using a common data structure can cause async-signal-safety problems, POSIX.1 does not define the behavior when any unsafe function is called in (or after a *longjmp*() or *siglongjmp*() out of) a signal handler that interrupts any unsafe function or the non-async-signal-safe processing equivalent to *exit*() that is performed after return from the initial call to *main*().

The only realtime extension to signal actions is the addition of the additional parameters to the signal-catching function. This extension has been explained and motivated in the previous section. In making this extension, though, developers of POSIX.1b ran into issues relating to function prototypes. In response to input from the POSIX.1 standard developers, members were added to the **sigaction** structure to specify function prototypes for the newer signal-catching function specified by POSIX.1b. These members follow changes that are being made to POSIX.1. Note that POSIX.1-2017 explicitly states that these fields may overlap so that a union can be defined. This enabled existing implementations of POSIX.1 to maintain binary-compatibility when these extensions were added.

The **siginfo_t** structure was adopted for passing the application-defined value to match existing practice, but the existing practice has no provision for an application-defined value, so this was added. Note that POSIX normally reserves the ``_t'' type designation for opaque types. The **siginfo_t** structure breaks with this convention to follow existing practice and thus promote

121806 portability.

121807 POSIX.1-2017 specifies several values for the *si_code* member of the **siginfo_t** structure. Some
121808 were introduced in POSIX.1b; others were XSI functionality in the Single UNIX Specification,
121809 Version 2 and Version 3, that has now become Base functionality. Historically, an *si_code* value of
121810 less than or equal to zero indicated that the signal was generated by a process via the *kill*()
121811 function, and values of *si_code* that provided additional information for implementation-
121812 generated signals, such as SIGFPE or SIGSEGV, were all positive. This functionality is partially
121813 specified for XSI systems in that if *si_code* is less than or equal to zero, the signal was generated
121814 by a process. However, since POSIX.1b did not specify that SI_USER (or SI_QUEUE) had a value
121815 less than or equal to zero, it is not true that when the signal is generated by a process, the value
121816 of *si_code* will always be less than or equal to zero. XSI applications should check whether *si_code*
121817 is SI_USER or SI_QUEUE in addition to checking whether it is less than or equal to zero.
121818 Applications on systems that do not support the XSI option should just check for SI_USER and
121819 SI_QUEUE.

121820 If an implementation chooses to define additional values for *si_code*, these values have to be
121821 different from the values of the non-signal-specific symbols specified by POSIX.1-2017. This will
121822 allow conforming applications to differentiate between signals generated by standard events
121823 and those generated by other implementation events in a manner compatible with existing
121824 practice.

121825 The unique values of *si_code* for the POSIX.1b asynchronous events have implications for
121826 implementations of, for example, asynchronous I/O or message passing in user space library
121827 code. Such an implementation will be required to provide a hidden interface to the signal
121828 generation mechanism that allows the library to specify the standard values of *si_code*.

121829 POSIX.1-2017 also specifies additional members of **siginfo_t**, beyond those that were in
121830 POSIX.1b. Like the *si_code* values mentioned above, these were XSI functionality in the Single
121831 UNIX Specification, Version 2 and Version 3, that has now become Base functionality. They
121832 provide additional information when *si_code* has one of the values that moved from XSI to Base.

121833 Although it is not explicitly visible to applications, there are additional semantics for signal
121834 actions implied by queued signals and their interaction with other POSIX.1b realtime functions.
121835 Specifically:

121836 It is not necessary to queue signals whose action is SIG_IGN.

121837 For implementations that support POSIX.1b timers, some interaction with the timer
121838 functions at signal delivery is implied to manage the timer overrun count.

121839 IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/5 is applied, reordering the RTS shaded
121840 text under the third and fourth paragraphs of the SIG_DFL description. This corrects an earlier
121841 editorial error in this section.

121842 IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/6 is applied, adding the *abort*() function
121843 to the list of async-signal-safe functions.

121844 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/4 is applied, adding the *sockatmark*()
121845 function to the list of functions that shall be either reentrant or non-interruptible by signals and
121846 shall be async-signal-safe.

121847 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0011 [690], XSH/TC2-2008/0012 [516],
121848 XSH/TC2-2008/0013 [692], XSH/TC2-2008/0014 [615], XSH/TC2-2008/0015 [516], and
121849 XSH/TC2-2008/0016 [807] are applied.

121850 *B.2.4.4 Signal Effects on Other Functions*

121851 The most common behavior of an interrupted function after a signal-catching function returns is
121852 for the interrupted function to give an [EINTR] error unless the SA_RESTART flag is in effect for
121853 the signal. However, there are a number of specific exceptions, including *sleep*( ) and certain
121854 situations with *read*( ) and *write*( ).

121855 The historical implementations of many functions defined by POSIX.1-2017 are not interruptible,
121856 but delay delivery of signals generated during their execution until after they complete. This is
121857 never a problem for functions that are guaranteed to complete in a short (imperceptible to a
121858 human) period of time. It is normally those functions that can suspend a process indefinitely or
121859 for long periods of time (for example, *wait*( ), *pause*( ), *sigsuspend*( ), *sleep*( ), or *read*( )/*write*( ) on a
121860 slow device like a terminal) that are interruptible. This permits applications to respond to
121861 interactive signals or to set timeouts on calls to most such functions with *alarm*( ). Therefore,
121862 implementations should generally make such functions (including ones defined as extensions)
121863 interruptible.

121864 Functions not mentioned explicitly as interruptible may be so on some implementations,
121865 possibly as an extension where the function gives an [EINTR] error. There are several functions
121866 (for example, *getpid*( ), *getuid*( )) that are specified as never returning an error, which can thus
121867 never be extended in this way.

121868 If a signal-catching function returns while the SA_RESTART flag is in effect, an interrupted
121869 function is restarted at the point it was interrupted. Conforming applications cannot make
121870 assumptions about the internal behavior of interrupted functions, even if the functions are
121871 async-signal-safe. For example, suppose the *read*( ) function is interrupted with SA_RESTART in
121872 effect, the signal-catching function closes the file descriptor being read from and returns, and the
121873 *read*( ) function is then restarted; in this case the application cannot assume that the *read*( )
121874 function will give an [EBADF] error, since *read*( ) might have checked the file descriptor for
121875 validity before being interrupted.

121876 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0017 [807] is applied.

121877 ## B.2.5 Standard I/O Streams

121878 Although the ISO C standard guarantees that, at program start-up, *stdin* is open for reading and
121879 *stdout* and *stderr* are open for writing, this guarantee is contingent (as are all guarantees made by
121880 the ISO C and POSIX standards) on the program being executed in a conforming environment.
121881 Programs executed with file descriptor 0 not open for reading or with file descriptor 1 or 2 not
121882 open for writing are executed in a non-conforming environment. Application writers are warned
121883 (in *exec*, *posix_spawn*( ), and Section C.2.7, on page 3735) not to execute a standard utility or a
121884 conforming application with file descriptor 0 not open for reading or with file descriptor 1 or 2
121885 not open for writing.

121886 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0018 [608] is applied.

121887 *B.2.5.1 Interaction of File Descriptors and Standard I/O Streams*

121888 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0019 [480] is applied.

121889 *B.2.5.2 Stream Orientation and Encoding Rules*

121890 There is no additional rationale provided for this section.

121891 B.2.6 STREAMS

121892 STREAMS are included into POSIX.1-2017 as part of the alignment with the Single UNIX
121893 Specification, but marked as an option in recognition that not all systems may wish to
121894 implement the facility. The option within POSIX.1-2017 is denoted by the XSR margin marker.
121895 The standard developers made this option independent of the XSI option. In this version of the
121896 standard this option is marked obsolescent.

121897 STREAMS are a method of implementing network services and other character-based
121898 input/output mechanisms, with the STREAM being a full-duplex connection between a process
121899 and a device. STREAMS provides direct access to protocol modules, and optional protocol
121900 modules can be interposed between the process-end of the STREAM and the device-driver at the
121901 device-end of the STREAM. Pipes can be implemented using the STREAMS mechanism, so they
121902 can provide process-to-process as well as process-to-device communications.

121903 This section introduces STREAMS I/O, the message types used to control them, an overview of
121904 the priority mechanism, and the interfaces used to access them.

121905 *B.2.6.1 Accessing STREAMS*

121906 There is no additional rationale provided for this section.

121907 B.2.7 XSI Interprocess Communication

121908 There are two forms of IPC supported as options in POSIX.1-2017. The traditional System V IPC
121909 routines derived from the SVID—that is, the *msg**(), *sem**(), and *shm**() interfaces—are
121910 mandatory on XSI-conformant systems. Thus, all XSI-conformant systems provide the same
121911 mechanisms for manipulating messages, shared memory, and semaphores.

121912 In addition, the POSIX Realtime Extension provides an alternate set of routines for those systems
121913 supporting the appropriate options.

121914 The application developer is presented with a choice: the System V interfaces or the POSIX
121915 interfaces (loosely derived from the Berkeley interfaces). The XSI profile prefers the System V
121916 interfaces, but the POSIX interfaces may be more suitable for realtime or other performance-
121917 sensitive applications.

121918 *B.2.7.1 IPC General Information*

121919 General information that is shared by all three mechanisms is described in this section. The
121920 common permissions mechanism is briefly introduced, describing the mode bits, and how they
121921 are used to determine whether or not a process has access to read or write/alter the appropriate
121922 instance of one of the IPC mechanisms. All other relevant information is contained in the
121923 reference pages themselves.

121924 The semaphore type of IPC allows processes to communicate through the exchange of
121925 semaphore values. A semaphore is a positive integer. Since many applications require the use of
121926 more than one semaphore, XSI-conformant systems have the ability to create sets or arrays of
121927 semaphores.

121928 Calls to support semaphores include:

121929 *semctl*( ), *semget*( ), *semop*( )

121930 Semaphore sets are created by using the *semget*( ) function.

121931 The message type of IPC allows processes to communicate through the exchange of data stored
121932 in buffers. This data is transmitted between processes in discrete portions known as messages.

121933 Calls to support message queues include:

121934 *msgctl*( ), *msgget*( ), *msgrcv*( ), *msgsnd*( )

121935 The shared memory type of IPC allows two or more processes to share memory and
121936 consequently the data contained therein. This is done by allowing processes to set up access to a
121937 common memory address space. This sharing of memory provides a fast means of exchange of
121938 data between processes.

121939 Calls to support shared memory include:

121940 *shmctl*( ), *shmdt*( ), *shmget*( )

121941 The *ftok*( ) interface is also provided.

121942 ### B.2.8 Realtime

121943 **Advisory Information**

121944 POSIX.1b contains an Informative Annex with proposed interfaces for ``realtime files''. These
121945 interfaces could determine groups of the exact parameters required to do ``direct I/O'' or
121946 ``extents''. These interfaces were objected to by a significant portion of the balloting group as too
121947 complex. A conforming application had little chance of correctly navigating the large parameter
121948 space to match its desires to the system. In addition, they only applied to a new type of file
121949 (realtime files) and they told the implementation exactly what to do as opposed to advising the
121950 implementation on application behavior and letting it optimize for the system the (portable)
121951 application was running on. For example, it was not clear how a system that had a disk array
121952 should set its parameters.

121953 There seemed to be several overall goals:

121954 Optimizing sequential access

121955 Optimizing caching behavior

121956 Optimizing I/O data transfer

121957 Preallocation

121958 The advisory interfaces, *posix_fadvise*( ) and *posix_madvise*( ), satisfy the first two goals. The
121959 POSIX_FADV_SEQUENTIAL and POSIX_MADV_SEQUENTIAL advice tells the
121960 implementation to expect serial access. Typically the system will prefetch the next several serial
121961 accesses in order to overlap I/O. It may also free previously accessed serial data if memory is
121962 tight. If the application is not doing serial access it can use POSIX_FADV_WILLNEED and
121963 POSIX_MADV_WILLNEED to accomplish I/O overlap, as required. When the application
121964 advises POSIX_FADV_RANDOM or POSIX_MADV_RANDOM behavior, the implementation
121965 usually tries to fetch a minimum amount of data with each request and it does not expect much
121966 locality. POSIX_FADV_DONTNEED and POSIX_MADV_DONTNEED allow the system to free
121967 up caching resources as the data will not be required in the near future.

121968 POSIX_FADV_NOREUSE tells the system that caching the specified data is not optimal. For file
121969 I/O, the transfer should go directly to the user buffer instead of being cached internally by the

implementation. To portably perform direct disk I/O on all systems, the application must perform its I/O transfers according to the following rules:

1. The user buffer should be aligned according to the {POSIX_REC_XFER_ALIGN} *pathconf*( ) variable.
2. The number of bytes transferred in an I/O operation should be a multiple of the {POSIX_ALLOC_SIZE_MIN} *pathconf*( ) variable.
3. The offset into the file at the start of an I/O operation should be a multiple of the {POSIX_ALLOC_SIZE_MIN} *pathconf*( ) variable.
4. The application should ensure that all threads which open a given file specify POSIX_FADV_NOREUSE to be sure that there is no unexpected interaction between threads using buffered I/O and threads using direct I/O to the same file.

In some cases, a user buffer must be properly aligned in order to be transferred directly to/from the device. The {POSIX_REC_XFER_ALIGN} *pathconf*( ) variable tells the application the proper alignment.

The preallocation goal is met by the space control function, *posix_fallocate*( ). The application can use *posix_fallocate*( ) to guarantee no [ENOSPC] errors and to improve performance by prepaying any overhead required for block allocation.

Implementations may use information conveyed by a previous *posix_fadvise*( ) call to influence the manner in which allocation is performed. For example, if an application did the following calls:

```
fd = open("file");
posix_fadvise(fd, offset, len, POSIX_FADV_SEQUENTIAL);
posix_fallocate(fd, len, size);
```

an implementation might allocate the file contiguously on disk.

Finally, the *pathconf*( ) variables {POSIX_REC_MIN_XFER_SIZE}, {POSIX_REC_MAX_XFER_SIZE}, and {POSIX_REC_INCR_XFER_SIZE} tell the application a range of transfer sizes that are recommended for best I/O performance.

Where bounded response time is required, the vendor can supply the appropriate settings of the advisories to achieve a guaranteed performance level.

The interfaces meet the goals while allowing applications using regular files to take advantage of performance optimizations. The interfaces tell the implementation expected application behavior which the implementation can use to optimize performance on a particular system with a particular dynamic load.

The *posix_memalign*( ) function was added to allow for the allocation of specifically aligned buffers; for example, for {POSIX_REC_XFER_ALIGN}.

The working group also considered the alternative of adding a function which would return an aligned pointer to memory within a user-supplied buffer. This was not considered to be the best method, because it potentially wastes large amounts of memory when buffers need to be aligned on large alignment boundaries.

122009 **Message Passing**

122010 This section provides the rationale for the definition of the message passing interface in
122011 POSIX.1-2017. This is presented in terms of the objectives, models, and requirements imposed
122012 upon this interface.

122013 Objectives

122014 Many applications, including both realtime and database applications, require a means of
122015 passing arbitrary amounts of data between cooperating processes comprising the overall
122016 application on one or more processors. Many conventional interfaces for interprocess
122017 communication are insufficient for realtime applications in that efficient and deterministic
122018 data passing methods cannot be implemented. This has prompted the definition of
122019 message passing interfaces providing these facilities:

122020 ‡ pen a message queue.

122021 ‡ end a message to a message queue.

122022 ‡ ceive a message from a queue, either synchronously or asynchronously.

122023 ‡ tes message queue attributes for flow and resource control.

122024 It is assumed that an application may consist of multiple cooperating processes and that
122025 these processes may wish to communicate and coordinate their activities. The message
122026 passing facility described in POSIX.1-2017 allows processes to communicate through
122027 system-wide queues. These message queues are accessed through names that may be
122028 pathnames. A message queue can be opened for use by multiple sending and/or multiple
122029 receiving processes.

122030 Background on Embedded Applications

122031 Interprocess communication utilizing message passing is a key facility for the construction
122032 of deterministic, high-performance realtime applications. The facility is present in all
122033 realtime systems and is the framework upon which the application is constructed. The
122034 performance of the facility is usually a direct indication of the performance of the resulting
122035 application.

122036 Realtime applications, especially for embedded systems, are typically designed around the
122037 performance constraints imposed by the message passing mechanisms. Applications for
122038 embedded systems are typically very tightly constrained. Application developers expect to
122039 design and control the entire system. In order to minimize system costs, the writer will
122040 attempt to use all resources to their utmost and minimize the requirement to add
122041 additional memory or processors.

122042 The embedded applications usually share address spaces and only a simple message
122043 passing mechanism is required. The application can readily access common data incurring
122044 only mutual-exclusion overheads. The models desired are the simplest possible with the
122045 application building higher-level facilities only when needed.

122046 Requirements

122047 The following requirements determined the features of the message passing facilities
122048 defined in POSIX.1-2017:

122049 ‡ Naming of Message Queues

122050 The mechanism for gaining access to a message queue is a pathname evaluated in a
122051 context that is allowed to be a file system name space, or it can be independent of
122052 any file system. This is a specific attempt to allow implementations based on either
122053 method in order to address both embedded systems and to also allow

122054 implementation in larger systems.

122055 The interface of *mq_open*() is defined to allow but not require the access control and
122056 name conflicts resulting from utilizing a file system for name resolution. All required
122057 behavior is specified for the access control case. Yet a conforming implementation,
122058 such as an embedded system kernel, may define that there are no distinctions
122059 between users and may define that all processes have all access privileges.

122060 ‡ mbEedded System Naming

122061 Embedded systems need to be able to utilize independent name spaces for accessing
122062 the various system objects. They typically do not have a file system, precluding its
122063 utilization as a common name resolution mechanism. The modularity of an
122064 embedded system limits the connections between separate mechanisms that can be
122065 allowed.

122066 Embedded systems typically do not have any access protection. Since the system
122067 does not support the mixing of applications from different areas, and usually does
122068 not even have the concept of an authorization entity, access control is not useful.

122069 ‡ arLge System Naming

122070 On systems with more functionality, the name resolution must support the ability to
122071 use the file system as the name resolution mechanism/object storage medium and to
122072 have control over access to the objects. Utilizing the pathname space can result in
122073 further errors when the names conflict with other objects.

122074 ‡ ixEd Size of Messages

122075 The interfaces impose a fixed upper bound on the size of messages that can be sent to
122076 a specific message queue. The size is set on an individual queue basis and cannot be
122077 changed dynamically.

122078 The purpose of the fixed size is to increase the ability of the system to optimize the
122079 implementation of *mq_send*() and *mq_receive*(). With fixed sizes of messages and
122080 fixed numbers of messages, specific message blocks can be pre-allocated. This
122081 eliminates a significant amount of checking for errors and boundary conditions.
122082 Additionally, an implementation can optimize data copying to maximize
122083 performance. Finally, with a restricted range of message sizes, an implementation is
122084 better able to provide deterministic operations.

122085 ‡ riPoritization of Messages

122086 Message prioritization allows the application to determine the order in which
122087 messages are received. Prioritization of messages is a key facility that is provided by
122088 most realtime kernels and is heavily utilized by the applications. The major purpose
122089 of having priorities in message queues is to avoid priority inversions in the message
122090 system, where a high-priority message is delayed behind one or more lower-priority
122091 messages. This allows the applications to be designed so that they do not need to be
122092 interrupted in order to change the flow of control when exceptional conditions occur.
122093 The prioritization does add additional overhead to the message operations in those
122094 cases it is actually used but a clever implementation can optimize for the FIFO case to
122095 make that more efficient.

122096 ‡ syAnchronous Notification

122097 The interface supports the ability to have a task asynchronously notified of the
122098 availability of a message on the queue. The purpose of this facility is to allow the task
122099 to perform other functions and yet still be notified that a message has become

available on the queue.

To understand the requirement for this function, it is useful to understand two models of application design: a single task performing multiple functions and multiple tasks performing a single function. Each of these models has advantages.

Asynchronous notification is required to build the model of a single task performing multiple operations. This model typically results from either the expectation that interruption is less expensive than utilizing a separate task or from the growth of the application to include additional functions.

Semaphores

Semaphores are a high-performance process synchronization mechanism. Semaphores are named by null-terminated strings of characters.

A semaphore is created using the *sem_init*() function or the *sem_open*() function with the O_CREAT flag set in *oflag*.

To use a semaphore, a process has to first initialize the semaphore or inherit an open descriptor for the semaphore via *fork*().

A semaphore preserves its state when the last reference is closed. For example, if a semaphore has a value of 13 when the last reference is closed, it will have a value of 13 when it is next opened.

When a semaphore is created, an initial state for the semaphore has to be provided. This value is a non-negative integer. Negative values are not possible since they indicate the presence of blocked processes. The persistence of any of these objects across a system crash or a system reboot is undefined. Conforming applications must not depend on any sort of persistence across a system reboot or a system crash.

Models and Requirements

A realtime system requires synchronization and communication between the processes comprising the overall application. An efficient and reliable synchronization mechanism has to be provided in a realtime system that will allow more than one schedulable process mutually-exclusive access to the same resource. This synchronization mechanism has to allow for the optimal implementation of synchronization or systems implementors will define other, more cost-effective methods.

At issue are the methods whereby multiple processes (tasks) can be designed and implemented to work together in order to perform a single function. This requires interprocess communication and synchronization. A semaphore mechanism is the lowest level of synchronization that can be provided by an operating system.

A semaphore is defined as an object that has an integral value and a set of blocked processes associated with it. If the value is positive or zero, then the set of blocked processes is empty; otherwise, the size of the set is equal to the absolute value of the semaphore value. The value of the semaphore can be incremented or decremented by any process with access to the semaphore and must be done as an indivisible operation. When a semaphore value is less than or equal to zero, any process that attempts to lock it again will block or be informed that it is not possible to perform the operation.

A semaphore may be used to guard access to any resource accessible by more than one schedulable task in the system. It is a global entity and not associated with any particular process. As such, a method of obtaining access to the semaphore has to be provided by the operating system. A process that wants access to a critical resource (section) has to wait on the semaphore that guards that resource. When the semaphore is locked on behalf of a

process, it knows that it can utilize the resource without interference by any other cooperating process in the system. When the process finishes its operation on the resource, leaving it in a well-defined state, it posts the semaphore, indicating that some other process may now obtain the resource associated with that semaphore.

In this section, mutexes and condition variables are specified as the synchronization mechanisms between threads.

These primitives are typically used for synchronizing threads that share memory in a single process. However, this section provides an option allowing the use of these synchronization interfaces and objects between processes that share memory, regardless of the method for sharing memory.

Much experience with semaphores shows that there are two distinct uses of synchronization: locking, which is typically of short duration; and waiting, which is typically of long or unbounded duration. These distinct usages map directly onto mutexes and condition variables, respectively.

Semaphores are provided in POSIX.1-2017 primarily to provide a means of synchronization for processes; these processes may or may not share memory. Mutexes and condition variables are specified as synchronization mechanisms between threads; these threads always share (some) memory. Both are synchronization paradigms that have been in widespread use for a number of years. Each set of primitives is particularly well matched to certain problems.

With respect to binary semaphores, experience has shown that condition variables and mutexes are easier to use for many synchronization problems than binary semaphores. The primary reason for this is the explicit appearance of a Boolean predicate that specifies when the condition wait is satisfied. This Boolean predicate terminates a loop, including the call to *pthread_cond_wait*(). As a result, extra wakeups are benign since the predicate governs whether the thread will actually proceed past the condition wait. With stateful primitives, such as binary semaphores, the wakeup in itself typically means that the wait is satisfied. The burden of ensuring correctness for such waits is thus placed on *all* signalers of the semaphore rather than on an *explicitly coded* Boolean predicate located at the condition wait. Experience has shown that the latter creates a major improvement in safety and ease-of-use.

Counting semaphores are well matched to dealing with producer/consumer problems, including those that might exist between threads of different processes, or between a signal handler and a thread. In the former case, there may be little or no memory shared by the processes; in the latter case, one is not communicating between co-equal threads, but between a thread and an interrupt-like entity. It is for these reasons that POSIX.1-2017 allows semaphores to be used by threads.

Mutexes and condition variables have been effectively used with and without priority inheritance, priority ceiling, and other attributes to synchronize threads that share memory. The efficiency of their implementation is comparable to or better than that of other synchronization primitives that are sometimes harder to use (for example, binary semaphores). Furthermore, there is at least one known implementation of Ada tasking that uses these primitives. Mutexes and condition variables together constitute an appropriate, sufficient, and complete set of inter-thread synchronization primitives.

Efficient multi-threaded applications require high-performance synchronization primitives. Considerations of efficiency and generality require a small set of primitives upon which more sophisticated synchronization functions can be built.

Standardization Issues

It is possible to implement very high-performance semaphores using test-and-set instructions on shared memory locations. The library routines that implement such a high-performance interface have to properly ensure that a *sem_wait*( ) or *sem_trywait*( ) operation that cannot be performed will issue a blocking semaphore system call or properly report the condition to the application. The same interface to the application program would be provided by a high-performance implementation.

B.2.8.1 Realtime Signals

Realtime Signals Extension

This portion of the rationale presents models, requirements, and standardization issues relevant to the Realtime Signals Extension. This extension provides the capability required to support reliable, deterministic, asynchronous notification of events. While a new mechanism, unencumbered by the historical usage and semantics of POSIX.1 signals, might allow for a more efficient implementation, the application requirements for event notification can be met with a small number of extensions to signals. Therefore, a minimal set of extensions to signals to support the application requirements is specified.

The realtime signal extensions specified in this section are used by other realtime functions requiring asynchronous notification:

Models

The model supported is one of multiple cooperating processes, each of which handles multiple asynchronous external events. Events represent occurrences that are generated as the result of some activity in the system. Examples of occurrences that can constitute an event include:

- Completion of an asynchronous I/O request
- Expiration of a POSIX.1b timer
- Arrival of an interprocess message
- Generation of a user-defined event

Processing of these events may occur synchronously via polling for event notifications or asynchronously via a software interrupt mechanism. Existing practice for this model is well established for traditional proprietary realtime operating systems, realtime executives, and realtime extended POSIX-like systems.

A contrasting model is that of ``cooperating sequential processes'' where each process handles a single priority of events via polling. Each process blocks while waiting for events, and each process depends on the preemptive, priority-based process scheduling mechanism to arbitrate between events of different priority that need to be processed concurrently. Existing practice for this model is also well established for small realtime executives that typically execute in an unprotected physical address space, but it is just emerging in the context of a fuller function operating system with multiple virtual address spaces.

It could be argued that the cooperating sequential process model, and the facilities supported by the POSIX Threads Extension obviate a software interrupt model. But, even with the cooperating sequential process model, the need has been recognized for a software interrupt model to handle exceptional conditions and process aborting, so the mechanism must be supported in any case. Furthermore, it is not the purview of POSIX.1-2017 to attempt to convince realtime practitioners that their current application

models based on software interrupts are ``broken'' and should be replaced by the cooperating sequential process model. Rather, it is the charter of POSIX.1-2017 to provide standard extensions to mechanisms that support existing realtime practice.

Requirements

This section discusses the following realtime application requirements for asynchronous event notification:

- Reliable delivery of asynchronous event notification

  The events notification mechanism guarantees delivery of an event notification. Asynchronous operations (such as asynchronous I/O and timers) that complete significantly after they are invoked have to guarantee that delivery of the event notification can occur at the time of completion.

- Prioritized handling of asynchronous event notifications

  The events notification mechanism supports the assigning of a user function as an event notification handler. Furthermore, the mechanism supports the preemption of an event handler function by a higher priority event notification and supports the selection of the highest priority pending event notification when multiple notifications (of different priority) are pending simultaneously.

  The model here is based on hardware interrupts. Asynchronous event handling allows the application to ensure that time-critical events are immediately processed when delivered, without the indeterminism of being at a random location within a polling loop. Use of handler priority allows the specification of how handlers are interrupted by other higher priority handlers.

- Differentiation between multiple occurrences of event notifications of the same type

  The events notification mechanism passes an application-defined value to the event handler function. This value can be used for a variety of purposes, such as enabling the application to identify which of several possible events of the same type (for example, timer expirations) has occurred.

- Polled reception of asynchronous event notifications

  The events notification mechanism supports blocking and non-blocking polls for asynchronous event notification.

  The polled mode of operation is often preferred over the interrupt mode by those practitioners accustomed to this model. Providing support for this model facilitates the porting of applications based on this model to POSIX.1b conforming systems.

- Deterministic response to asynchronous event notifications

  The events notification mechanism does not preclude implementations that provide deterministic event dispatch latency and minimizes the number of system calls needed to use the event facilities during realtime processing.

Rationale for Extension

POSIX.1 signals have many of the characteristics necessary to support the asynchronous handling of event notifications, and the Realtime Signals Extension addresses the following deficiencies in the POSIX.1 signal mechanism:

- Signals do not support reliable delivery of event notification. Subsequent occurrences of a pending signal are not guaranteed to be delivered.

122281 ‡ Signals do not support prioritized delivery of event notifications. The order of signal
122282 delivery when multiple unblocked signals are pending is undefined.

122283 ‡ Signals do not support the differentiation between multiple signals of the same type.

122284 *B.2.8.2 Asynchronous I/O*

122285 Many applications need to interact with the I/O subsystem in an asynchronous manner. The
122286 asynchronous I/O mechanism provides the ability to overlap application processing and I/O
122287 operations initiated by the application. The asynchronous I/O mechanism allows a single
122288 process to perform I/O simultaneously to a single file multiple times or to multiple files
122289 multiple times.

122290 **Overview**

122291 Asynchronous I/O operations proceed in logical parallel with the processing done by the
122292 application after the asynchronous I/O has been initiated. Other than this difference,
122293 asynchronous I/O behaves similarly to normal I/O using *read*(), *write*(), *lseek*(), and *fsync*().
122294 The effect of issuing an asynchronous I/O request is as if a separate thread of execution were to
122295 perform atomically the implied *lseek*() operation, if any, and then the requested I/O operation
122296 (either *read*(), *write*(), or *fsync*()). There is no seek implied with a call to *aio_fsync*(). Concurrent
122297 asynchronous operations and synchronous operations applied to the same file update the file as
122298 if the I/O operations had proceeded serially.

122299 When asynchronous I/O completes, a signal can be delivered to the application to indicate the
122300 completion of the I/O. This signal can be used to indicate that buffers and control blocks used
122301 for asynchronous I/O can be reused. Signal delivery is not required for an asynchronous
122302 operation and may be turned off on a per-operation basis by the application. Signals may also be
122303 synchronously polled using *aio_suspend*(), *sigtimedwait*(), or *sigwaitinfo*().

122304 Normal I/O has a return value and an error status associated with it. Asynchronous I/O
122305 returns a value and an error status when the operation is first submitted, but that only relates to
122306 whether the operation was successfully queued up for servicing. The I/O operation itself also
122307 has a return status and an error value. To allow the application to retrieve the return status and
122308 the error value, functions are provided that, given the address of an asynchronous I/O control
122309 block, yield the return and error status associated with the operation. Until an asynchronous I/O
122310 operation is done, its error status is [EINPROGRESS]. Thus, an application can poll for
122311 completion of an asynchronous I/O operation by waiting for the error status to become equal to
122312 a value other than [EINPROGRESS]. The return status of an asynchronous I/O operation is
122313 undefined so long as the error status is equal to [EINPROGRESS].

122314 Storage for asynchronous operation return and error status may be limited. Submission of
122315 asynchronous I/O operations may fail if this storage is exceeded. When an application retrieves
122316 the return status of a given asynchronous operation, therefore, any system-maintained storage
122317 used for this status and the error status may be reclaimed for use by other asynchronous
122318 operations.

122319 Asynchronous I/O can be performed on file descriptors that have been enabled for POSIX.1b
122320 synchronized I/O. In this case, the I/O operation still occurs asynchronously, as defined herein;
122321 however, the asynchronous operation I/O in this case is not completed until the I/O has reached
122322 either the state of synchronized I/O data integrity completion or synchronized I/O file integrity
122323 completion, depending on the sort of synchronized I/O that is enabled on the file descriptor.

122324 **Models**

122325 Three models illustrate the use of asynchronous I/O: a journalization model, a data acquisition
122326 model, and a model of the use of asynchronous I/O in supercomputing applications.

122327 Journalization Model

122328 Many realtime applications perform low-priority journalizing functions. Journalizing
122329 requires that logging records be queued for output without blocking the initiating process.

122330 Data Acquisition Model

122331 A data acquisition process may also serve as a model. The process has two or more
122332 channels delivering intermittent data that must be read within a certain time. The process
122333 issues one asynchronous read on each channel. When one of the channels needs data
122334 collection, the process reads the data and posts it through an asynchronous write to
122335 secondary memory for future processing.

122336 Supercomputing Model

122337 The supercomputing community has used asynchronous I/O much like that specified in
122338 POSIX.1 for many years. This community requires the ability to perform multiple I/O
122339 operations to multiple devices with a minimal number of entries to ``the system''; each
122340 entry to ``the system'' provokes a major delay in operations when compared to the normal
122341 progress made by the application. This existing practice motivated the use of combined
122342 *lseek*( ) and *read*( ) or *write*( ) calls, as well as the *lio_listio*( ) call. Another common practice is
122343 to disable signal notification for I/O completion, and simply poll for I/O completion at
122344 some interval by which the I/O should be completed. Likewise, interfaces like *aio_cancel*( )
122345 have been in successful commercial use for many years. Note also that an underlying
122346 implementation of asynchronous I/O will require the ability, at least internally, to cancel
122347 outstanding asynchronous I/O, at least when the process exits. (Consider an asynchronous
122348 read from a terminal, when the process intends to exit immediately.)

122349 **Requirements**

122350 Asynchronous input and output for realtime implementations have these requirements:

122351 The ability to queue multiple asynchronous read and write operations to a single open
122352 instance. Both sequential and random access should be supported.

122353 The ability to queue asynchronous read and write operations to multiple open instances.

122354 The ability to obtain completion status information by polling and/or asynchronous event
122355 notification.

122356 Asynchronous event notification on asynchronous I/O completion is optional.

122357 It has to be possible for the application to associate the event with the *aiocbp* for the
122358 operation that generated the event.

122359 The ability to cancel queued requests.

122360 The ability to wait upon asynchronous I/O completion in conjunction with other types of
122361 events.

122362 The ability to accept an *aio_read*( ) and an *aio_cancel*( ) for a device that accepts a *read*( ), and
122363 the ability to accept an *aio_write*( ) and an *aio_cancel*( ) for a device that accepts a *write*( ).
122364 This does not imply that the operation is asynchronous.

Standardization Issues

The following issues are addressed by the standardization of asynchronous I/O:

Rationale for New Interface

Non-blocking I/O does not satisfy the needs of either realtime or high-performance computing models; these models require that a process overlap program execution and I/O processing. Realtime applications will often make use of direct I/O to or from the address space of the process, or require synchronized (unbuffered) I/O; they also require the ability to overlap this I/O with other computation. In addition, asynchronous I/O allows an application to keep a device busy at all times, possibly achieving greater throughput. Supercomputing and database architectures will often have specialized hardware that can provide true asynchrony underlying the logical asynchrony provided by this interface. In addition, asynchronous I/O should be supported by all types of files and devices in the same manner.

Effect of Buffering

If asynchronous I/O is performed on a file that is buffered prior to being actually written to the device, it is possible that asynchronous I/O will offer no performance advantage over normal I/O; the cycles *stolen* to perform the asynchronous I/O will be taken away from the running process and the I/O will occur at interrupt time. This potential lack of gain in performance in no way obviates the need for asynchronous I/O by realtime applications, which very often will use specialized hardware support, multiple processors, and/or unbuffered, synchronized I/O.

B.2.8.3 Memory Management

All memory management and shared memory definitions are located in the **<sys/mman.h>** header. This is for alignment with historical practice.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/7 is applied, correcting the shading and margin markers in the introduction to Section 2.8.3.1.

Memory Locking Functions

This portion of the rationale presents models, requirements, and standardization issues relevant to process memory locking.

Models

Realtime systems that conform to POSIX.1-2017 are expected (and desired) to be supported on systems with demand-paged virtual memory management, non-paged swapping memory management, and physical memory systems with no memory management hardware. The general case, however, is the demand-paged, virtual memory system with each POSIX process running in a virtual address space. Note that this includes architectures where each process resides in its own virtual address space and architectures where the address space of each process is only a portion of a larger global virtual address space.

The concept of memory locking is introduced to eliminate the indeterminacy introduced by paging and swapping, and to support an upper bound on the time required to access the memory mapped into the address space of a process. Ideally, this upper bound will be the same as the time required for the processor to access ``main memory'', including any address translation and cache miss overheads. But some implementations ‡primarily on mainframes—will not actually force locked pages to be loaded and held resident in main memory. Rather, they will handle locked pages so that accesses to these pages will meet the

performance metrics for locked process memory in the implementation. Also, although it is not, for example, the intention that this interface, as specified, be used to lock process memory into ``cache'', it is conceivable that an implementation could support a large static RAM memory and define this as ``main memory'' and use a large[r] dynamic RAM as ``backing store''. These interfaces could then be interpreted as supporting the locking of process memory into the static RAM. Support for multiple levels of backing store would require extensions to these interfaces.

Implementations may also use memory locking to guarantee a fixed translation between virtual and physical addresses where such is beneficial to improving determinacy for direct-to/from-process input/output. POSIX.1-2017 does not guarantee to the application that the virtual-to-physical address translations, if such exist, are fixed, because such behavior would not be implementable on all architectures on which implementations of POSIX.1-2017 are expected. But POSIX.1-2017 does mandate that an implementation define, for the benefit of potential users, whether or not locking guarantees fixed translations.

Memory locking is defined with respect to the address space of a process. Only the pages mapped into the address space of a process may be locked by the process, and when the pages are no longer mapped into the address space—for whatever reason ‡the locks established with respect to that address space are removed. Shared memory areas warrant special mention, as they may be mapped into more than one address space or mapped more than once into the address space of a process; locks may be established on pages within these areas with respect to several of these mappings. In such a case, the lock state of the underlying physical pages is the logical OR of the lock state with respect to each of the mappings. Only when all such locks have been removed are the shared pages considered unlocked.

In recognition of the page granularity of Memory Management Units (MMU), and in order to support locking of ranges of address space, memory locking is defined in terms of ``page'' granularity. That is, for the interfaces that support an address and size specification for the region to be locked, the address must be on a page boundary, and all pages mapped by the specified range are locked, if valid. This means that the length is implicitly rounded up to a multiple of the page size. The page size is implementation-defined and is available to applications as a compile-time symbolic constant or at runtime via *sysconf*( ).

A ``real memory'' POSIX.1b implementation that has no MMU could elect not to support these interfaces, returning [ENOSYS]. But an application could easily interpret this as meaning that the implementation would unconditionally page or swap the application when such is not the case. It is the intention of POSIX.1-2017 that such a system could define these interfaces as ``NO-OPs'', returning success without actually performing any function except for mandated argument checking.

Requirements

For realtime applications, memory locking is generally considered to be required as part of application initialization. This locking is performed after an application has been loaded (that is, *exec*'d) and the program remains locked for its entire lifetime. But to support applications that undergo major mode changes where, in one mode, locking is required, but in another it is not, the specified interfaces allow repeated locking and unlocking of memory within the lifetime of a process.

When a realtime application locks its address space, it should not be necessary for the application to then ``touch'' all of the pages in the address space to guarantee that they are resident or else suffer potential paging delays the first time the page is referenced. Thus, POSIX.1-2017 requires that the pages locked by the specified interfaces be resident when

the locking functions return successfully.

Many architectures support system-managed stacks that grow automatically when the current extent of the stack is exceeded. A realtime application has a requirement to be able to ``preallocate'' sufficient stack space and lock it down so that it will not suffer page faults to grow the stack during critical realtime operation. There was no consensus on a portable way to specify how much stack space is needed, so POSIX.1-2017 supports no specific interface for preallocating stack space. But an application can portably lock down a specific amount of stack space by specifying MCL_FUTURE in a call to *mlockall*( ) and then calling a dummy function that declares an automatic array of the desired size.

Memory locking for realtime applications is also generally considered to be an ``all or nothing'' proposition. That is, the entire process, or none, is locked down. But, for applications that have well-defined sections that need to be locked and others that do not, POSIX.1-2017 supports an optional set of interfaces to lock or unlock a range of process addresses. Reasons for locking down a specific range include:

- Asynchronous event handler function that must respond to external events in a deterministic manner such that page faults cannot be tolerated
- Input/output ``buffer'' area that is the target for direct-to-process I/O, and the overhead of implicit locking and unlocking for each I/O call cannot be tolerated

Finally, locking is generally viewed as an ``application-wide'' function. That is, the application is globally aware of which regions are locked and which are not over time. This is in contrast to a function that is used temporarily within a ``third party'' library routine whose function is unknown to the application, and therefore must have no ``side-effects''. The specified interfaces, therefore, do not support ``lock stacking'' or ``lock nesting'' within a process. But, for pages that are shared between processes or mapped more than once into a process address space, ``lock stacking'' is essentially mandated by the requirement that unlocking of pages that are mapped by more that one process or more than once by the same process does not affect locks established on the other mappings.

There was some support for ``lock stacking'' so that locking could be transparently used in functions or opaque modules. But the consensus was not to burden all implementations with lock stacking (and reference counting), and an implementation option was proposed. There were strong objections to the option because applications would have to support both options in order to remain portable. The consensus was to eliminate lock stacking altogether, primarily through overwhelming support for the System V ``m[un]lock[all]'' interface on which POSIX.1-2017 is now based.

Locks are not inherited across *fork*( )s because some implementations implement *fork*( ) by creating new address spaces for the child. In such an implementation, requiring locks to be inherited would lead to new situations in which a fork would fail due to the inability of the system to lock sufficient memory to lock both the parent and the child. The consensus was that there was no benefit to such inheritance. Note that this does not mean that locks are removed when, for instance, a thread is created in the same address space.

Similarly, locks are not inherited across *exec* because some implementations implement *exec* by unmapping all of the pages in the address space (which, by definition, removes the locks on these pages), and maps in pages of the *exec*'d image. In such an implementation, requiring locks to be inherited would lead to new situations in which *exec* would fail. Reporting this failure would be very cumbersome to detect in time to report to the calling process, and no appropriate mechanism exists for informing the *exec*'d process of its status.

It was determined that, if the newly loaded application required locking, it was the responsibility of that application to establish the locks. This is also in keeping with the

general view that it is the responsibility of the application to be aware of all locks that are established.

There was one request to allow (not mandate) locks to be inherited across *fork*(), and a request for a flag, MCL_INHERIT, that would specify inheritance of memory locks across *exec*s. Given the difficulties raised by this and the general lack of support for the feature in POSIX.1-2017, it was not added. POSIX.1-2017 does not preclude an implementation from providing this feature for administrative purposes, such as a ``run'' command that will lock down and execute a specified application. Additionally, the rationale for the objection equated *fork*() with creating a thread in the address space. POSIX.1-2017 does not mandate releasing locks when creating additional threads in an existing process.

Standardization Issues

One goal of POSIX.1-2017 is to define a set of primitives that provide the necessary functionality for realtime applications, with consideration for the needs of other application domains where such were identified, which is based to the extent possible on existing industry practice.

The Memory Locking option is required by many realtime applications to tune performance. Such a facility is accomplished by placing constraints on the virtual memory system to limit paging of time of the process or of critical sections of the process. This facility should not be used by most non-realtime applications.

Optional features provided in POSIX.1-2017 allow applications to lock selected address ranges with the caveat that the process is responsible for being aware of the page granularity of locking and the unnested nature of the locks.

Mapped Files Functions

The memory mapped files functionality provides a mechanism that allows a process to access files by directly incorporating file data into its address space. Once a file is ``mapped'' into a process address space, the data can be manipulated by instructions as memory. The use of mapped files can significantly reduce I/O data movement since file data does not have to be copied into process data buffers as in *read*() and *write*(). If more than one process maps a file, its contents are shared among them. This provides a low overhead mechanism by which processes can synchronize and communicate.

Historical Perspective

Realtime applications have historically been implemented using a collection of cooperating processes or tasks. In early systems, these processes ran on bare hardware (that is, without an operating system) with no memory relocation or protection. The application paradigms that arose from this environment involve the sharing of data between the processes.

When realtime systems were implemented on top of vendor-supplied operating systems, the paradigm or performance benefits of direct access to data by multiple processes was still deemed necessary. As a result, operating systems that claim to support realtime applications must support the shared memory paradigm.

Additionally, a number of realtime systems provide the ability to map specific sections of the physical address space into the address space of a process. This ability is required if an application is to obtain direct access to memory locations that have specific properties (for example, refresh buffers or display devices, dual ported memory locations, DMA target locations). The use of this ability is common enough to warrant some degree of standardization of its interface. This ability overlaps the general paradigm of shared memory in that, in both instances, common global objects are made addressable by individual processes or tasks.

Finally, a number of systems also provide the ability to map process addresses to files. This provides both a general means of sharing persistent objects, and using files in a manner that optimizes memory and swapping space usage.

Simple shared memory is clearly a special case of the more general file mapping capability. In addition, there is relatively widespread agreement and implementation of the file mapping interface. In these systems, many different types of objects can be mapped (for example, files, memory, devices, and so on) using the same mapping interfaces. This approach both minimizes interface proliferation and maximizes the generality of programs using the mapping interfaces.

Memory Mapped Files Usage

A memory object can be concurrently mapped into the address space of one or more processes. The *mmap*() and *munmap*() functions allow a process to manipulate their address space by mapping portions of memory objects into it and removing them from it. When multiple processes map the same memory object, they can share access to the underlying data. Implementations may restrict the size and alignment of mappings to be on *page*-size boundaries. The page size, in bytes, is the value of the system-configurable variable {PAGESIZE}, typically accessed by calling *sysconf*() with a *name* argument of _SC_PAGESIZE. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

To map memory, a process first opens a memory object. The *ftruncate*() function can be used to contract or extend the size of the memory object even when the object is currently mapped. If the memory object is extended, the contents of the extended areas are zeros.

After opening a memory object, the application maps the object into its address space using the *mmap*() function call. Once a mapping has been established, it remains mapped until unmapped with *munmap*(), even if the memory object is closed. The *mprotect*() function can be used to change the memory protections initially established by *mmap*().

A *close*() of the file descriptor, while invalidating the file descriptor itself, does not unmap any mappings established for the memory object. The address space, including all mapped regions, is inherited on *fork*(). The entire address space is unmapped on process termination or by successful calls to any of the *exec* family of functions.

The *msync*() function is used to force mapped file data to permanent storage.

Effects on Other Functions

With memory mapped files, the operation of the *open*(), *creat*(), and *unlink*() functions are a natural result of using the file system name space to map the global names for memory objects.

The *ftruncate*() function can be used to set the length of a sharable memory object.

The meaning of *stat*() fields other than the size and protection information is undefined on implementations where memory objects are not implemented using regular files. When regular files are used, the times reflect when the implementation updated the file image of the data, not when a process updated the data in memory.

The operations of *fdopen*(), *write*(), *read*(), and *lseek*() were made unspecified for objects opened with *shm_open*(), so that implementations that did not implement memory objects as regular files would not have to support the operation of these functions on shared memory objects.

The behavior of memory objects with respect to *close*(), *dup*(), *dup2*(), *open*(), *close*(), *fork*(), *_exit*(), and the *exec* family of functions is the same as the behavior of the existing

122600 practice of the *mmap*( ) function.

122601 A memory object can still be referenced after a close. That is, any mappings made to the
122602 file are still in effect, and reads and writes that are made to those mappings are still valid
122603 and are shared with other processes that have the same mapping. Likewise, the memory
122604 object can still be used if any references remain after its name(s) have been deleted. Any
122605 references that remain after a close must not appear to the application as file descriptors.

122606 This is existing practice for *mmap*( ) and *close*( ). In addition, there are already mappings
122607 present (text, data, stack) that do not have open file descriptors. The text mapping in
122608 particular is considered a reference to the file containing the text. The desire was to treat all
122609 mappings by the process uniformly. Also, many modern implementations use *mmap*( ) to
122610 implement shared libraries, and it would not be desirable to keep file descriptors for each
122611 of the many libraries an application can use. It was felt there were many other existing
122612 programs that used this behavior to free a file descriptor, and thus POSIX.1-2017 could not
122613 forbid it and still claim to be using existing practice.

122614 For implementations that implement memory objects using memory only, memory objects
122615 will retain the memory allocated to the file after the last close and will use that same
122616 memory on the next open. Note that closing the memory object is not the same as deleting
122617 the name, since the memory object is still defined in the memory object name space.

122618 The locks of *fcntl*( ) do not block any read or write operation, including read or write access
122619 to shared memory or mapped files. In addition, implementations that only support shared
122620 memory objects should not be required to implement record locks. The reference to *fcntl*( )
122621 is added to make this point explicitly. The other *fcntl*( ) commands are useful with shared
122622 memory objects.

122623 The size of pages that mapping hardware may be able to support may be a configurable
122624 value, or it may change based on hardware implementations. The addition of the
122625 _SC_PAGESIZE parameter to the *sysconf*( ) function is provided for determining the
122626 mapping page size at runtime.

122627 **Shared Memory Functions**

122628 Implementations may support the Shared Memory Objects option independently of memory
122629 mapped files. Shared memory objects are named regions of storage that may be independent of
122630 the file system and can be mapped into the address space of one or more processes to allow
122631 them to share the associated memory.

122632 Requirements

122633 Shared memory is used to share data among several processes, each potentially running at
122634 different priority levels, responding to different inputs, or performing separate tasks.
122635 Shared memory is not just simply providing common access to data, it is providing the
122636 fastest possible communication between the processes. With one memory write operation,
122637 a process can pass information to as many processes as have the memory region mapped.

122638 As a result, shared memory provides a mechanism that can be used for all other
122639 interprocess communication facilities. It may also be used by an application for
122640 implementing more sophisticated mechanisms than semaphores and message queues.

122641 The need for a shared memory interface is obvious for virtual memory systems, where the
122642 operating system is directly preventing processes from accessing each other's data.
122643 However, in unprotected systems, such as those found in some embedded controllers, a
122644 shared memory interface is needed to provide a portable mechanism to allocate a region of
122645 memory to be shared and then to communicate the address of that region to other
122646 processes.

122647 This, then, provides the minimum functionality that a shared memory interface must have
122648 in order to support realtime applications: to allocate and name an object to be mapped into
122649 memory for potential sharing (*open*( ) or *shm_open*( )), and to make the memory object
122650 available within the address space of a process (*mmap*( )). To complete the interface, a
122651 mechanism to release the claim of a process on a shared memory object (*munmap*( )) is also
122652 needed, as well as a mechanism for deleting the name of a sharable object that was
122653 previously created (*unlink*( ) or *shm_unlink*( )).

122654 After a mapping has been established, an implementation should not have to provide
122655 services to maintain that mapping. All memory writes into that area will appear
122656 immediately in the memory mapping of that region by any other processes.

122657 Thus, requirements include:

122658 ‡ Support creation of sharable memory objects and the mapping of these objects into
122659 the address space of a process.

122660 ‡ Sharable memory objects should be accessed by global names accessible from all
122661 processes.

122662 ‡ Support the mapping of specific sections of physical address space (such as a
122663 memory mapped device) into the address space of a process. This should not be
122664 done by the process specifying the actual address, but again by an implementation-
122665 defined global name (such as a special device name) dedicated to this purpose.

122666 ‡ Support the mapping of discrete portions of these memory objects.

122667 ‡ Support for minimum hardware configurations that contain no physical media on
122668 which to store shared memory contents permanently.

122669 ‡ The ability to preallocate the entire shared memory region so that minimum
122670 hardware configurations without virtual memory support can guarantee contiguous
122671 space.

122672 ‡ The maximizing of performance by not requiring functionality that would require
122673 implementation interaction above creating the shared memory area and returning
122674 the mapping.

122675 Note that the above requirements do not preclude:

122676 ‡ The sharable memory object from being implemented using actual files on an actual
122677 file system.

122678 ‡ The global name that is accessible from all processes being restricted to a file system
122679 area that is dedicated to handling shared memory.

122680 ‡ An implementation not providing implementation-defined global names for the
122681 purpose of physical address mapping.

122682 Shared Memory Objects Usage

122683 If the Shared Memory Objects option is supported, a shared memory object may be
122684 created, or opened if it already exists, with the *shm_open*( ) function. If the shared memory
122685 object is created, it has a length of zero. The *ftruncate*( ) function can be used to set the size
122686 of the shared memory object after creation. The *shm_unlink*( ) function removes the name
122687 for a shared memory object created by *shm_open*( ).

122688 Shared Memory Overview

122689 The shared memory facility defined by POSIX.1-2017 usually results in memory locations
122690 being added to the address space of the process. The implementation returns the address

of the new space to the application by means of a pointer. This works well in languages like C. However, in languages without pointer types it will not work. In the bindings for such a language, either a special COMMON section will need to be defined (which is unlikely), or the binding will have to allow existing structures to be mapped. The implementation will likely have to place restrictions on the size and alignment of such structures or will have to map a suitable region of the address space of the process into the memory object, and thus into other processes. These are issues for that particular language binding. For POSIX.1-2017, however, the practice will not be forbidden, merely undefined.

Two potentially different name spaces are used for naming objects that may be mapped into process address spaces. When using memory mapped files, files may be accessed via *open*(). When the Shared Memory Objects option is supported, sharable memory objects that might not be files may be accessed via the *shm_open*() function. These operations are not mutually-exclusive.

Some implementations supporting the Shared Memory Objects option may choose to implement the shared memory object name space as part of the file system name space. There are several reasons for this:

- allows applications to prevent name conflicts by use of the directory structure.
- uses an existing mechanism for accessing global objects and prevents the creation of a new mechanism for naming global objects.

In such implementations, memory objects can be implemented using regular files, if that is what the implementation chooses. The *shm_open*() function can be implemented as an *open*() call in a fixed directory with the O_CLOEXEC flag set. The *shm_unlink*() function can be implemented as an *unlink*() call.

On the other hand, it is also expected that small embedded systems that support the Shared Memory Objects option may wish to implement shared memory without having any file systems present. In this case, the implementations may choose to use a simple string valued name space for shared memory regions. The *shm_open*() function permits either type of implementation.

Some implementations have hardware that supports protection of mapped data from certain classes of access and some do not. Systems that supply this functionality support the memory protection functionality.

Some implementations restrict size, alignment, and protections to be on *page*-size boundaries. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size. Applications on implementations that do support larger pages must be cognizant of the page size since this is the alignment and protection boundary.

Simple embedded implementations may have a 1-byte page size and only support the Shared Memory Objects option. This provides simple shared memory between processes without requiring mapping hardware.

POSIX.1-2017 specifically allows a memory object to remain referenced after a close because that is existing practice for the *mmap*() function.

122731 **Typed Memory Functions**

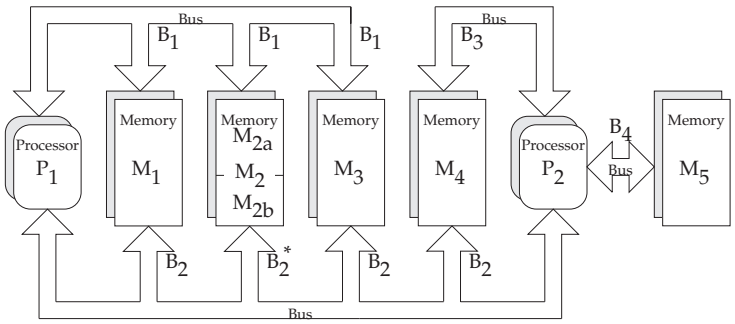
122732 Implementations may support the Typed Memory Objects option without supporting either the
122733 Shared Memory option or memory mapped files. Types memory objects are pools of specialized
122734 storage, different from the main memory resource normally used by a processor to hold code
122735 and data, that can be mapped into the address space of one or more processes.

122736 Model

122737 Realtime systems conforming to one of the POSIX.13 realtime profiles are expected (and
122738 desired) to be supported on systems with more than one type or pool of memory (for
122739 example, SRAM, DRAM, ROM, EPROM, EEPROM), where each type or pool of memory
122740 may be accessible by one or more processors via one or more buses (ports). Memory
122741 mapped files, shared memory objects, and the language-specific storage allocation
122742 operators (*malloc*() for the ISO C standard, *new* for ISO Ada) fail to provide application
122743 program interfaces versatile enough to allow applications to control their utilization of
122744 such diverse memory resources. The typed memory interfaces *posix_typed_mem_open*(),
122745 *posix_mem_offset*(), *posix_typed_mem_get_info*(), *mmap*(), and *munmap*() defined herein
122746 support the model of typed memory described below.

122747 For purposes of this model, a system comprises several processors (for example, P_1 and
122748 P_2), several physical memory pools (for example, M_1, M_2, M_{2a}, M_{2b}, M_3, M_4, and M_5), and
122749 several buses or ``ports'' (for example, B_1, B_2, B_3, and B_4) interconnecting the various
122750 processors and memory pools in some system-specific way. Notice that some memory
122751 pools may be contained in others (for example, M_{2a} and M_{2b} are contained in M_2).

122752 Figure B-1 shows an example of such a model. In a system like this, an application should
122753 be able to perform the following operations:



* All addresses in pool M_2 (comprising pools M_{2a} and M_{2b}) accessible via port B_1.
Addresses in pool M_{2b} are also accessible via port B_2.
Addresses in pool M_{2a} are *not* accessible via port B_2.

122754 **Figure B-1** Example of a System with Typed Memory

122755 ‡ýpEd Memory Allocation

122756 An application should be able to allocate memory dynamically from the desired pool
122757 using the desired bus, and map it into the address space of a process. For example,
122758 processor P_1 can allocate some portion of memory pool M_1 through port B_1, treating
122759 all unmapped subareas of M_1 as a heap-storage resource from which memory may be
122760 allocated. This portion of memory is mapped into address space of the process, and
122761 subsequently deallocated when unmapped from all processes.

‡ Using the Same Storage Region from Different Buses

An application process with a mapped region of storage that is accessed from one bus should be able to map that same storage area at another address (subject to page size restrictions detailed in *mmap*()), to allow it to be accessed from another bus. For example, processor P_1 may wish to access the same region of memory pool M_{2b} both through ports B_1 and B_2.

‡ Passing Typed Memory Regions

Several application processes running on the same or different processors may wish to share a particular region of a typed memory pool. Each process or processor may wish to access this region through different buses. For example, processor P_1 may want to share a region of memory pool M_4 with processor P_2, and they may be required to use buses B_2 and B_3, respectively, to minimize bus contention. A problem arises here when a process allocates and maps a portion of fragmented memory and then wants to share this region of memory with another process, either in the same processor or different processors. The solution adopted is to allow the first process to find out the memory map (offsets and lengths) of all the different fragments of memory that were mapped into its address space, by repeatedly calling *posix_mem_offset*(). Then, this process can pass the offsets and lengths obtained to the second process, which can then map the same memory fragments into its address space.

‡ Contiguous Allocation

The problem of finding the memory map of the different fragments of the memory pool that were mapped into logically contiguous addresses of a given process can be solved by requesting contiguous allocation. For example, a process in P_1 can allocate 10 Kbytes of physically contiguous memory from M_3-B_1, and obtain the offset (within pool M_3) of this block of memory. Then, it can pass this offset (and the length) to a process in P_2 using some interprocess communication mechanism. The second process can map the same block of memory by using the offset transferred and specifying M_3-B_2.

‡ Unallocated Mapping

Any subarea of a memory pool that is mapped to a process, either as the result of an allocation request or an explicit mapping, is normally unavailable for allocation. Special processes such as debuggers, however, may need to map large areas of a typed memory pool, yet leave those areas available for allocation.

Typed memory allocation and mapping has to coexist with storage allocation operators like *malloc*(), but systems are free to choose how to implement this coexistence. For example, it may be system configuration-dependent if all available system memory is made part of one of the typed memory pools or if some part will be restricted to conventional allocation operators. Equally system configuration-dependent may be the availability of operators like *malloc*() to allocate storage from certain typed memory pools. It is not excluded to configure a system such that a given named pool, P_1, is in turn split into non-overlapping named subpools. For example, M_1-B_1, M_2-B_1, and M_3-B_1 could also be accessed as one common pool M_{123}-B_1. A call to *malloc*() on P_1 could work on such a larger pool while full optimization of memory usage by P_1 would require typed memory allocation at the subpool level.

Existing Practice

OS-9 provides for the naming (numbering) and prioritization of memory types by a system administrator. It then provides APIs to request memory allocation of typed (colored)

memory by number, and to generate a bus address from a mapped memory address (translate). When requesting colored memory, the user can specify type 0 to signify allocation from the first available type in priority order.

HP-RT presents interfaces to map different kinds of storage regions that are visible through a VME bus, although it does not provide allocation operations. It also provides functions to perform address translation between VME addresses and virtual addresses. It represents a VME-bus unique solution to the general problem.

The PSOS approach is similar (that is, based on a pre-established mapping of bus address ranges to specific memories) with a concept of segments and regions (regions dynamically allocated from a heap which is a special segment). Therefore, PSOS does not fully address the general allocation problem either. PSOS does not have a ``process''-based model, but more of a ``thread''-only-based model of multi-tasking. So mapping to a process address space is not an issue.

QNX uses the System V approach of opening specially named devices (shared memory segments) and using *mmap*() to then gain access from the process. They do not address allocation directly, but once typed shared memory can be mapped, an ``allocation manager'' process could be written to handle requests for allocation.

The System V approach also included allocation, implemented by opening yet other special ``devices'' which allocate, rather than appearing as a whole memory object.

The Orkid realtime kernel interface definition has operations to manage memory ``regions'' and ``pools'', which are areas of memory that may reflect the differing physical nature of the memory. Operations to allocate memory from these regions and pools are also provided.

Requirements

Existing practice in SVID-derived UNIX systems relies on functionality similar to *mmap*() and its related interfaces to achieve mapping and allocation of typed memory. However, the issue of sharing typed memory (allocated or mapped) and the complication of multiple ports are not addressed in any consistent way by existing UNIX system practice. Part of this functionality is existing practice in specialized realtime operating systems. In order to solidify the capabilities implied by the model above, the following requirements are imposed on the interface:

‡ Identification of Typed Memory Pools and Ports

All processes (running in all processors) in the system are able to identify a particular (system configured) typed memory pool accessed through a particular (system configured) port by a name. That name is a member of a name space common to all these processes, but need not be the same name space as that containing ordinary pathnames. The association between memory pools/ports and corresponding names is typically established when the system is configured. The ``open'' operation for typed memory objects should be distinct from the *open*() function, for consistency with other similar services, but implementable on top of *open*(). This implies that the handle for a typed memory object will be a file descriptor.

‡ Allocation and Mapping of Typed Memory

Once a typed memory object has been identified by a process, it is possible to both map user-selected subareas of that object into process address space and to map system-selected (that is, dynamically allocated) subareas of that object, with user-specified length, into process address space. It is also possible to determine the maximum length of memory allocation that may be requested from a given typed

memory object.

‡ Sharing Typed Memory

Two or more processes are able to share portions of typed memory, either user-selected or dynamically allocated. This requirement applies also to dynamically allocated regions of memory that are composed of several non-contiguous pieces.

‡ Contiguous Allocation

For dynamic allocation, it is the user's option whether the system is required to allocate a contiguous subarea within the typed memory object, or whether it is permitted to allocate discontiguous fragments which appear contiguous in the process mapping. Contiguous allocation simplifies the process of sharing allocated typed memory, while discontiguous allocation allows for potentially better recovery of deallocated typed memory.

‡ Accessing Typed Memory Through Different Ports

Once a subarea of a typed memory object has been mapped, it is possible to determine the location and length corresponding to a user-selected portion of that object within the memory pool. This location and length can then be used to remap that portion of memory for access from another port. If the referenced portion of typed memory was allocated discontiguously, the length thus determined may be shorter than anticipated, and the user code must adapt to the value returned.

‡ Deallocation

When a previously mapped subarea of typed memory is no longer mapped by any process in the system—as a result of a call or calls to *munmap*() ‡ that subarea becomes potentially reusable for dynamic allocation; actual reuse of the subarea is a function of the dynamic typed memory allocation policy.

‡ Unallocated Mapping

It must be possible to map user-selected subareas of a typed memory object without marking that subarea as unavailable for allocation. This option is not the default behavior, and requires appropriate privileges.

Scenario

The following scenario will serve to clarify the use of the typed memory interfaces.

Process A running on P_1 (see Figure B-1, on page 3605) wants to allocate some memory from memory pool M_2, and it wants to share this portion of memory with process B running on P_2. Since P_2 only has access to the lower part of M_2, both processes will use the memory pool named M_{2b} which is the part of M_2 that is accessible both from P_1 and P_2. The operations that both processes need to perform are shown below:

‡ Allocating Typed Memory

Process A calls *posix_typed_mem_open*() with the name **/typed.m2b-b1** and a *tflag* of POSIX_TYPED_MEM_ALLOCATE to get a file descriptor usable for allocating from pool M_{2b} accessed through port B_1. It then calls *mmap*() with this file descriptor requesting a length of 4 096 bytes. The system allocates two discontiguous blocks of sizes 1 024 and 3 072 bytes within M_{2b}. The *mmap*() function returns a pointer to a 4 096-byte array in process A's logical address space, mapping the allocated blocks contiguously. Process A can then utilize the array, and store data in it.

‡ Determining the Location of the Allocated Blocks

Process A can determine the lengths and offsets (relative to M_{2b}) of the two blocks allocated, by using the following procedure: First, process A calls *posix_mem_offset*( ) with the address of the first element of the array and length 4 096. Upon return, the offset and length (1 024 bytes) of the first block are returned. A second call to *posix_mem_offset*( ) is then made using the address of the first element of the array plus 1 024 (the length of the first block), and a new length of 4 096–1 024. If there were more fragments allocated, this procedure could have been continued within a loop until the offsets and lengths of all the blocks were obtained. Notice that this relatively complex procedure can be avoided if contiguous allocation is requested (by opening the typed memory object with the *tflag* POSIX_TYPED_MEM_ALLOCATE_CONTIG).

‡ Passing Data Across Processes

Process A passes the two offset values and lengths obtained from the *posix_mem_offset*( ) calls to process B running on P_2, via some form of interprocess communication. Process B can gain access to process A's data by calling *posix_typed_mem_open*( ) with the name **/typed.m2b-b2** and a *tflag* of zero, then using two *mmap*( ) calls on the resulting file descriptor to map the two subareas of that typed memory object to its own address space.

Rationale for no *mem_alloc*( ) and *mem_free*( )

The standard developers had originally proposed a pair of new flags to *mmap*( ) which, when applied to a typed memory object descriptor, would cause *mmap*( ) to allocate dynamically from an unallocated and unmapped area of the typed memory object. Deallocation was similarly accomplished through the use of *munmap*( ). This was rejected by the ballot group because it excessively complicated the (already rather complex) *mmap*( ) interface and introduced semantics useful only for typed memory, to a function which must also map shared memory and files. They felt that a memory allocator should be built on top of *mmap*( ) instead of being incorporated within the same interface, much as the ISO C standard libraries build *malloc*( ) on top of the virtual memory mapping functions *brk*( ) and *sbrk*( ). This would eliminate the complicated semantics involved with unmapping only part of an allocated block of typed memory.

To attempt to achieve ballot group consensus, typed memory allocation and deallocation was first migrated from *mmap*( ) and *munmap*( ) to a pair of complementary functions modeled on the ISO C standard *malloc*( ) and *free*( ). The *mem_alloc*( ) function specified explicitly the typed memory object (typed memory pool/access port) from which allocation takes place, unlike *malloc*( ) where the memory pool and port are unspecified. The *mem_free*( ) function handled deallocation. These new semantics still met all of the requirements detailed above without modifying the behavior of *mmap*( ) except to allow it to map specified areas of typed memory objects. An implementation would have been free to implement *mem_alloc*( ) and *mem_free*( ) over *mmap*( ), through *mmap*( ), or independently but cooperating with *mmap*( ).

The ballot group was queried to see if this was an acceptable alternative, and while there was some agreement that it achieved the goal of removing the complicated semantics of allocation from the *mmap*( ) interface, several balloters realized that it just created two additional functions that behaved, in great part, like *mmap*( ). These balloters proposed an alternative which has been implemented here in place of a separate *mem_alloc*( ) and *mem_free*( ). This alternative is based on four specific suggestions:

1. The *posix_typed_mem_open*() function should provide a flag which specifies ``allocate on *mmap*()'' (otherwise, *mmap*() just maps the underlying object). This allows things roughly similar to **/dev/zero** *versus* **/dev/swap**. Two such flags have been implemented, one of which forces contiguous allocation.

2. The *posix_mem_offset*() function is acceptable because it can be applied usefully to mapped objects in general. It should return the file descriptor of the underlying object.

3. The *mem_get_info*() function in an earlier draft should be renamed *posix_typed_mem_get_info*() because it is not generally applicable to memory objects. It should probably return the file descriptor's allocation attribute. The renaming of the function has been implemented, but having it return a piece of information which is readily known by an application without this function has been rejected. Its whole purpose is to query the typed memory object for attributes that are not user-specified, but determined by the implementation.

4. There should be no separate *mem_alloc*() or *mem_free*() functions. Instead, using *mmap*() on a typed memory object opened with an ``allocate on *mmap*()'' flag should be used to force allocation. These are precisely the semantics defined in the current draft.

Rationale for no Typed Memory Access Management

The working group had originally defined an additional interface (and an additional kind of object: typed memory master) to establish and dissolve mappings to typed memory on behalf of devices or processors which were independent of the operating system and had no inherent capability to directly establish mappings on their own. This was to have provided functionality similar to device driver interfaces such as *physio*() and their underlying bus-specific interfaces (for example, *mballoc*()) which serve to set up and break down DMA pathways, and derive mapped addresses for use by hardware devices and processor cards.

The ballot group felt that this was beyond the scope of POSIX.1 and its amendments. Furthermore, the removal of interrupt handling interfaces from a preceding amendment (the IEEE Std 1003.1d-1999) during its balloting process renders these typed memory access management interfaces an incomplete solution to portable device management from a user process; it would be possible to initiate a device transfer to/from typed memory, but impossible to handle the transfer-complete interrupt in a portable way.

To achieve ballot group consensus, all references to typed memory access management capabilities were removed. The concept of portable interfaces from a device driver to both operating system and hardware is being addressed by the Uniform Driver Interface (UDI) industry forum, with formal standardization deferred until proof of concept and industry-wide acceptance and implementation.

B.2.8.4 Process Scheduling

IEEE PASC Interpretation 1003.1 #96 has been applied, adding the *pthread_setschedprio*() function. This was added since previously there was no way for a thread to lower its own priority without going to the tail of the threads list for its new priority. This capability is necessary to bound the duration of priority inversion encountered by a thread.

The following portion of the rationale presents models, requirements, and standardization issues relevant to process scheduling; see also Section B.2.9.4 (on page 3651).

In an operating system supporting multiple concurrent processes, the system determines the

order in which processes execute to meet implementation-defined goals. For time-sharing systems, the goal is to enhance system throughput and promote fairness; the application is provided with little or no control over this sequencing function. While this is acceptable and desirable behavior in a time-sharing system, it is inappropriate in a realtime system; realtime applications must specifically control the execution sequence of their concurrent processes in order to meet externally defined response requirements.

In POSIX.1-2017, the control over process sequencing is provided using a concept of scheduling policies. These policies, described in detail in this section, define the behavior of the system whenever processor resources are to be allocated to competing processes. Only the behavior of the policy is defined; conforming implementations are free to use any mechanism desired to achieve the described behavior.

Models

In an operating system supporting multiple concurrent processes, the system determines the order in which processes execute and might force long-running processes to yield to other processes at certain intervals. Typically, the scheduling code is executed whenever an event occurs that might alter the process to be executed next.

The simplest scheduling strategy is a ``first-in, first-out'' (FIFO) dispatcher. Whenever a process becomes runnable, it is placed on the end of a ready list. The process at the front of the ready list is executed until it exits or becomes blocked, at which point it is removed from the list. This scheduling technique is also known as ``run-to-completion'' or ``run-to-block''.

A natural extension to this scheduling technique is the assignment of a ``non-migrating priority'' to each process. This policy differs from strict FIFO scheduling in only one respect: whenever a process becomes runnable, it is placed at the end of the list of processes runnable at that priority level. When selecting a process to run, the system always selects the first process from the highest priority queue with a runnable process. Thus, when a process becomes unblocked, it will preempt a running process of lower priority without otherwise altering the ready list. Further, if a process elects to alter its priority, it is removed from the ready list and reinserted, using its new priority, according to the policy above.

While the above policy might be considered unfriendly in a time-sharing environment in which multiple users require more balanced resource allocation, it could be ideal in a realtime environment for several reasons. The most important of these is that it is deterministic: the highest-priority process is always run and, among processes of equal priority, the process that has been runnable for the longest time is executed first. Because of this determinism, cooperating processes can implement more complex scheduling simply by altering their priority. For instance, if processes at a single priority were to reschedule themselves at fixed time intervals, a time-slice policy would result.

In a dedicated operating system in which all processes are well-behaved realtime applications, non-migrating priority scheduling is sufficient. However, many existing implementations provide for more complex scheduling policies.

POSIX.1-2017 specifies a linear scheduling model. In this model, every process in the system has a priority. The system scheduler always dispatches a process that has the highest (generally the most time-critical) priority among all runnable processes in the system. As long as there is only one such process, the dispatching policy is trivial. When multiple processes of equal priority are eligible to run, they are ordered according to a strict run-to-completion (FIFO) policy.

The priority is represented as a positive integer and is inherited from the parent process.

For processes running under a fixed priority scheduling policy, the priority is never altered except by an explicit function call.

It was determined arbitrarily that larger integers correspond to ``higher priorities''.

Certain implementations might impose restrictions on the priority ranges to which processes can be assigned. There also can be restrictions on the set of policies to which processes can be set.

Requirements

Realtime processes require that scheduling be fast and deterministic, and that it guarantees to preempt lower priority processes.

Thus, given the linear scheduling model, realtime processes require that they be run at a priority that is higher than other processes. Within this framework, realtime processes are free to yield execution resources to each other in a completely portable and implementation-defined manner.

As there is a generally perceived requirement for processes at the same priority level to share processor resources more equitably, provisions are made by providing a scheduling policy (that is, SCHED_RR) intended to provide a timeslice-like facility.

Note: The following topics assume that low numeric priority implies low scheduling criticality and *vice versa*.

Rationale for New Interface

Realtime applications need to be able to determine when processes will run in relation to each other. It must be possible to guarantee that a critical process will run whenever it is runnable; that is, whenever it wants to for as long as it needs. SCHED_FIFO satisfies this requirement. Additionally, SCHED_RR was defined to meet a realtime requirement for a well-defined time-sharing policy for processes at the same priority.

It would be possible to use the BSD *setpriority*() and *getpriority*() functions by redefining the meaning of the ``nice'' parameter according to the scheduling policy currently in use by the process. The System V *nice*() interface was felt to be undesirable for realtime because it specifies an adjustment to the ``nice'' value, rather than setting it to an explicit value. Realtime applications will usually want to set priority to an explicit value. Also, System V *nice*() does not allow for changing the priority of another process.

With the POSIX.1b interfaces, the traditional ``nice'' value does not affect the SCHED_FIFO or SCHED_RR scheduling policies. If a ``nice'' value is supported, it is implementation-defined whether it affects the SCHED_OTHER policy.

An important aspect of POSIX.1-2017 is the explicit description of the queuing and preemption rules. It is critical, to achieve deterministic scheduling, that such rules be stated clearly in POSIX.1-2017.

POSIX.1-2017 does not address the interaction between priority and swapping. The issues involved with swapping and virtual memory paging are extremely implementation-defined and would be nearly impossible to standardize at this point. The proposed scheduling paradigm, however, fully describes the scheduling behavior of runnable processes, of which one criterion is that the working set be resident in memory. Assuming the existence of a portable interface for locking portions of a process in memory, paging behavior need not affect the scheduling of realtime processes.

POSIX.1-2017 also does not address the priorities of ``system'' processes. In general, these processes should always execute in low-priority ranges to avoid conflict with other realtime processes. Implementations should document the priority ranges in which system

123087 processes run.

123088 The default scheduling policy is not defined. The effect of I/O interrupts and other system
123089 processing activities is not defined. The temporary lending of priority from one process to
123090 another (such as for the purposes of affecting freeing resources) by the system is not
123091 addressed. Preemption of resources is not addressed. Restrictions on the ability of a
123092 process to affect other processes beyond a certain level (influence levels) is not addressed.

123093 The rationale used to justify the simple time-quantum scheduler is that it is common
123094 practice to depend upon this type of scheduling to ensure ``fair'' distribution of processor
123095 resources among portions of the application that must interoperate in a serial fashion. Note
123096 that POSIX.1-2017 is silent with respect to the setting of this time quantum, or whether it is
123097 a system-wide value or a per-process value, although it appears that the prevailing
123098 realtime practice is for it to be a system-wide value.

123099 In a system with N processes at a given priority, all processor-bound, in which the time
123100 quantum is equal for all processes at a specific priority level, the following assumptions
123101 are made of such a scheduling policy:

123102 1. A time quantum Q exists and the current process will own control of the processor
123103 for at least a duration of Q and will have the processor for a duration of Q.

123104 2. The Nth process at that priority will control a processor within a duration of $(N-1)$
123105 $\times Q$.

123106 These assumptions are necessary to provide equal access to the processor and bounded
123107 response from the application.

123108 The assumptions hold for the described scheduling policy only if no system overhead,
123109 such as interrupt servicing, is present. If the interrupt servicing load is non-zero, then one
123110 of the two assumptions becomes fallacious, based upon how Q is measured by the system.

123111 If Q is measured by clock time, then the assumption that the process obtains a duration Q
123112 processor time is false if interrupt overhead exists. Indeed, a scenario can be constructed
123113 with N processes in which a single process undergoes complete processor starvation if a
123114 peripheral device, such as an analog-to-digital converter, generates significant interrupt
123115 activity periodically with a period of $N \times Q$.

123116 If Q is measured as actual processor time, then the assumption that the Nth process runs in
123117 within the duration $(N-1) \times Q$ is false.

123118 It should be noted that SCHED_FIFO suffers from interrupt-based delay as well. However,
123119 for SCHED_FIFO, the implied response of the system is ``as soon as possible'', so that the
123120 interrupt load for this case is a vendor selection and not a compliance issue.

123121 With this in mind, it is necessary either to complete the definition by including bounds on
123122 the interrupt load, or to modify the assumptions that can be made about the scheduling
123123 policy.

123124 Since the motivation of inclusion of the policy is common usage, and since current
123125 applications do not enjoy the luxury of bounded interrupt load, item (2) above is sufficient
123126 to express existing application needs and is less restrictive in the standard definition. No
123127 difference in interface is necessary.

123128 In an implementation in which the time quantum is equal for all processes at a specific
123129 priority, our assumptions can then be restated as:

123130 ‡ A time quantum Q exists, and a processor-bound process will be rescheduled after a
123131 duration of, at most, Q. Time quantum Q may be defined in either wall clock time or
123132 execution time.

123133 ‡ In general, the *N*th process of a priority level should wait no longer than $(N-1) \times Q$
123134 time to execute, assuming no processes exist at higher priority levels.

123135 ‡ ó No process should wait indefinitely.

123136 For implementations supporting per-process time quanta, these assumptions can be
123137 readily extended.

123138 **Sporadic Server Scheduling Policy**

123139 The sporadic server is a mechanism defined for scheduling aperiodic activities in time-critical
123140 realtime systems. This mechanism reserves a certain bounded amount of execution capacity for
123141 processing aperiodic events at a high priority level. Any aperiodic events that cannot be
123142 processed within the bounded amount of execution capacity are executed in the background at a
123143 low priority level. Thus, a certain amount of execution capacity can be guaranteed to be
123144 available for processing periodic tasks, even under burst conditions in the arrival of aperiodic
123145 processing requests (that is, a large number of requests in a short time interval). The sporadic
123146 server also simplifies the schedulability analysis of the realtime system, because it allows
123147 aperiodic processes or threads to be treated as if they were periodic. The sporadic server was
123148 first described by Sprunt, et al.

123149 The key concept of the sporadic server is to provide and limit a certain amount of computation
123150 capacity for processing aperiodic events at their assigned normal priority, during a time interval
123151 called the ``replenishment period''. Once the entity controlled by the sporadic server mechanism
123152 is initialized with its period and execution-time budget attributes, it preserves its execution
123153 capacity until an aperiodic request arrives. The request will be serviced (if there are no higher
123154 priority activities pending) as long as there is execution capacity left. If the request is completed,
123155 the actual execution time used to service it is subtracted from the capacity, and a replenishment
123156 of this amount of execution time is scheduled to happen one replenishment period after the
123157 arrival of the aperiodic request. If the request is not completed, because there is no execution
123158 capacity left, then the aperiodic process or thread is assigned a lower background priority. For
123159 each portion of consumed execution capacity the execution time used is replenished after one
123160 replenishment period. At the time of replenishment, if the sporadic server was executing at a
123161 background priority level, its priority is elevated to the normal level. Other similar
123162 replenishment policies have been defined, but the one presented here represents a compromise
123163 between efficiency and implementation complexity.

123164 The interface that appears in this section defines a new scheduling policy for threads and
123165 processes that behaves according to the rules of the sporadic server mechanism. Scheduling
123166 attributes are defined and functions are provided to allow the user to set and get the parameters
123167 that control the scheduling behavior of this mechanism, namely the normal and low priority, the
123168 replenishment period, the maximum number of pending replenishment operations, and the
123169 initial execution-time budget.

123170 Scheduling Aperiodic Activities

123171 Virtually all realtime applications are required to process aperiodic activities. In many
123172 cases, there are tight timing constraints that the response to the aperiodic events must
123173 meet. Usual timing requirements imposed on the response to these events are:

123174 ‡ The effects of an aperiodic activity on the response time of lower priority activities
123175 must be controllable and predictable.

123176 ‡ The system must provide the fastest possible response time to aperiodic events.

123177 ‡ It must be possible to take advantage of all the available processing bandwidth not
123178 needed by time-critical activities to enhance average-case response times to aperiodic
123179 events.

Traditional methods for scheduling aperiodic activities are background processing, polling tasks, and direct event execution:

- Background processing consists of assigning a very low priority to the processing of aperiodic events. It utilizes all the available bandwidth in the system that has not been consumed by higher priority threads. However, it is very difficult, or impossible, to meet requirements on average-case response time, because the aperiodic entity has to wait for the execution of all other entities which have higher priority.

- Polling consists of creating a periodic process or thread for servicing aperiodic requests. At regular intervals, the polling entity is started and its services accumulated pending aperiodic requests. If no aperiodic requests are pending, the polling entity suspends itself until its next period. Polling allows the aperiodic requests to be processed at a higher priority level. However, worst and average-case response times of polling entities are a direct function of the polling period, and there is execution overhead for each polling period, even if no event has arrived. If the deadline of the aperiodic activity is short compared to the inter-arrival time, the polling frequency must be increased to guarantee meeting the deadline. For this case, the increase in frequency can dramatically reduce the efficiency of the system and, therefore, its capacity to meet all deadlines. Yet, polling represents a good way to handle a large class of practical problems because it preserves system predictability, and because the amortized overhead drops as load increases.

- Direct event execution consists of executing the aperiodic events at a high fixed-priority level. Typically, the aperiodic event is processed by an interrupt service routine as soon as it arrives. This technique provides predictable response times for aperiodic events, but makes the response times of all lower priority activities completely unpredictable under burst arrival conditions. Therefore, if the density of aperiodic event arrivals is unbounded, it may be a dangerous technique for time-critical systems. Yet, for those cases in which the physics of the system imposes a bound on the event arrival rate, it is probably the most efficient technique.

- The sporadic server scheduling algorithm combines the predictability of the polling approach with the short response times of the direct event execution. Thus, it allows systems to meet an important class of application requirements that cannot be met by using the traditional approaches. Multiple sporadic servers with different attributes can be applied to the scheduling of multiple classes of aperiodic events, each with different kinds of timing requirements, such as individual deadlines, average response times, and so on. It also has many other interesting applications for realtime, such as scheduling producer/consumer tasks in time-critical systems, limiting the effects of faults on the estimation of task execution-time requirements, and so on.

Existing Practice

The sporadic server has been used in different kinds of applications, including military avionics, robot control systems, industrial automation systems, and so on. There are examples of many systems that cannot be successfully scheduled using the classic approaches, such as direct event execution, or polling, and are schedulable using a sporadic server scheduler. The sporadic server algorithm itself can successfully schedule all systems scheduled with direct event execution or polling.

The sporadic server scheduling policy has been implemented as a commercial product in the run-time system of the Verdix Ada compiler. There are also many applications that have used a much less efficient application-level sporadic server. These realtime

applications would benefit from a sporadic server scheduler implemented at the scheduler level.

Library-Level *versus* Kernel-Level Implementation

The sporadic server interface described in this section requires the sporadic server policy to be implemented at the same level as the scheduler. This means that the process sporadic server must be implemented at the kernel level and the thread sporadic server policy implemented at the same level as the thread scheduler; that is, kernel or library level.

In an earlier interface for the sporadic server, this mechanism was implementable at a different level than the scheduler. This feature allowed the implementor to choose between an efficient scheduler-level implementation, or a simpler user or library-level implementation. However, the working group considered that this interface made the use of sporadic servers more complex, and that library-level implementations would lack some of the important functionality of the sporadic server, namely the limitation of the actual execution time of aperiodic activities. The working group also felt that the interface described in this chapter does not preclude library-level implementations of threads intended to provide efficient low-overhead scheduling for those threads that are not scheduled under the sporadic server policy.

Range of Scheduling Priorities

Each of the scheduling policies supported in POSIX.1-2017 has an associated range of priorities. The priority ranges for each policy might or might not overlap with the priority ranges of other policies. For time-critical realtime applications it is usual for periodic and aperiodic activities to be scheduled together in the same processor. Periodic activities will usually be scheduled using the SCHED_FIFO scheduling policy, while aperiodic activities may be scheduled using SCHED_SPORADIC. Since the application developer will require complete control over the relative priorities of these activities in order to meet his timing requirements, it would be desirable for the priority ranges of SCHED_FIFO and SCHED_SPORADIC to overlap completely. Therefore, although POSIX.1-2017 does not require any particular relationship between the different priority ranges, it is recommended that these two ranges should coincide.

Dynamically Setting the Sporadic Server Policy

Several members of the working group requested that implementations should not be required to support dynamically setting the sporadic server scheduling policy for a thread. The reason is that this policy may have a high overhead for library-level implementations of threads, and if threads are allowed to dynamically set this policy, this overhead can be experienced even if the thread does not use that policy. By disallowing the dynamic setting of the sporadic server scheduling policy, these implementations can accomplish efficient scheduling for threads using other policies. If a strictly conforming application needs to use the sporadic server policy, and is therefore willing to pay the overhead, it must set this policy at the time of thread creation.

Limitation of the Number of Pending Replenishments

The number of simultaneously pending replenishment operations must be limited for each sporadic server for two reasons: an unlimited number of replenishment operations would need an unlimited number of system resources to store all the pending replenishment operations; on the other hand, in some implementations each replenishment operation will represent a source of priority inversion (just for the duration of the replenishment operation) and thus, the maximum amount of replenishments must be bounded to guarantee bounded response times. The way in which the number of replenishments is bounded is by lowering the priority of the sporadic server to *sched_ss_low_priority* when

the number of pending replenishments has reached its limit. In this way, no new replenishments are scheduled until the number of pending replenishments decreases.

In the sporadic server scheduling policy defined in POSIX.1-2017, the application can specify the maximum number of pending replenishment operations for a single sporadic server, by setting the value of the *sched_ss_max_repl* scheduling parameter. This value must be between one and {SS_REPL_MAX}, which is a maximum limit imposed by the implementation. The limit {SS_REPL_MAX} must be greater than or equal to {_POSIX_SS_REPL_MAX}, which is defined to be four in POSIX.1-2017. The minimum limit of four was chosen so that an application can at least guarantee that four different aperiodic events can be processed during each interval of length equal to the replenishment period.

B.2.8.5 Clocks and Timers

Clocks

POSIX.1-2017 and the ISO C standard both define functions for obtaining system time. Implicit behind these functions is a mechanism for measuring passage of time. This specification makes this mechanism explicit and calls it a clock. The CLOCK_REALTIME clock required by POSIX.1-2017 is a higher resolution version of the clock that maintains POSIX.1 system time. This is a ``system-wide'' clock, in that it is visible to all processes and, were it possible for multiple processes to all read the clock at the same time, they would see the same value.

An extensible interface was defined, with the ability for implementations to define additional clocks. This was done because of the observation that many realtime platforms support multiple clocks, and it was desired to fit this model within the standard interface. But implementation-defined clocks need not represent actual hardware devices, nor are they necessarily system-wide.

Timers

Two timer types are required for a system to support realtime applications:

1. One-shot

   A one-shot timer is a timer that is armed with an initial expiration time, either relative to the current time or at an absolute time (based on some timing base, such as time in seconds and nanoseconds since the Epoch). The timer expires once and then is disarmed. With the specified facilities, this is accomplished by setting the *it_value* member of the *value* argument to the desired expiration time and the *it_interval* member to zero.

2. Periodic

   A periodic timer is a timer that is armed with an initial expiration time, again either relative or absolute, and a repetition interval. When the initial expiration occurs, the timer is reloaded with the repetition interval and continues counting. With the specified facilities, this is accomplished by setting the *it_value* member of the *value* argument to the desired initial expiration time and the *it_interval* member to the desired repetition interval.

For both of these types of timers, the time of the initial timer expiration can be specified in two ways:

1. Relative (to the current time)
2. Absolute

Examples of Using Realtime Timers

In the diagrams below, *S* indicates a program schedule, *R* shows a schedule method request, and *E* suggests an internal operating system event.

‡ Periodic Timer: Data Logging

During an experiment, it might be necessary to log realtime data periodically to an internal buffer or to a mass storage device. With a periodic scheduling method, a logging module can be started automatically at fixed time intervals to log the data.

Program schedule is requested every 10 seconds.

```
    R          S          S          S          S          S
----+----+----+----+----+----+----+----+----+----+----+----+--->
    5   10   15   20   25   30   35   40   45   50   55
```

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with the TIMER_ABSTIME flag reset, and with an initial expiration value and a repetition interval of 10 seconds.

‡ One-shot Timer (Relative Time): Device Initialization

In an emission test environment, large sample bags are used to capture the exhaust from a vehicle. The exhaust is purged from these bags before each and every test. With a one-shot timer, a module could initiate the purge function and then suspend itself for a predetermined period of time while the sample bags are prepared.

Program schedule requested 20 seconds after call is issued.

```
    R                    S
----+----+----+----+----+----+----+----+----+----+----+----+--->
    5   10   15   20   25   30   35   40   45   50   55
```

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with the TIMER_ABSTIME flag reset, and with an initial expiration value of 20 seconds and a repetition interval of zero.

Note that if the program wishes merely to suspend itself for the specified interval, it could more easily use *nanosleep*( ).

‡ One-shot Timer (Absolute Time): Data Transmission

The results from an experiment are often moved to a different system within a network for post-processing or archiving. With an absolute one-shot timer, a module that moves data from a test-cell computer to a host computer can be automatically scheduled on a daily basis.

Program schedule requested for 2:30 a.m.

```
          R                                        S
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+----->
   23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00
```

123363 [Time of Day]

123364 To achieve this type of scheduling using the specified facilities, a per-process timer
123365 would be allocated based on clock ID CLOCK_REALTIME. Then the timer would be
123366 armed via a call to *timer_settime*( ) with the TIMER_ABSTIME flag set, and an initial
123367 expiration value equal to 2:30 a.m. of the next day.

123368 ‡ Periodic Timer (Relative Time): Signal Stabilization

123369 Some measurement devices, such as emission analyzers, do not respond
123370 instantaneously to an introduced sample. With a periodic timer with a relative initial
123371 expiration time, a module that introduces a sample and records the average response
123372 could suspend itself for a predetermined period of time while the signal is stabilized
123373 and then sample at a fixed rate.

123374 Program schedule requested 15 seconds after call is issued and every 2 seconds
123375 thereafter.

123376
```
   R               S S S S S S S S S S S S S S S S S S S S
---+----+----+----+----+----+----+----+----+----+----+----+--->
    5   10   15   20   25   30   35   40   45   50   55
```

123379 [Time (in Seconds)]

123380 To achieve this type of scheduling using the specified facilities, one would allocate a
123381 per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be
123382 armed via a call to *timer_settime*( ) with TIMER_ABSTIME flag reset, and with an
123383 initial expiration value of 15 seconds and a repetition interval of 2 seconds.

123384 ‡ Periodic Timer (Absolute Time): Work Shift-related Processing

123385 Resource utilization data is useful when time to perform experiments is being
123386 scheduled at a facility. With a periodic timer with an absolute initial expiration time,
123387 a module can be scheduled at the beginning of a work shift to gather resource
123388 utilization data throughout the shift. This data can be used to allocate resources
123389 effectively to minimize bottlenecks and delays and maximize facility throughput.

123390 Program schedule requested for 2:00 a.m. and every 15 minutes thereafter.

123391
```
         R                                   S  S  S  S  S  S
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+----->
   23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00
```

123394 [Time of Day]

123395 To achieve this type of scheduling using the specified facilities, one would allocate a
123396 per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be
123397 armed via a call to *timer_settime*( ) with TIMER_ABSTIME flag set, and with an initial
123398 expiration value equal to 2:00 a.m. and a repetition interval equal to 15 minutes.

123399 Relationship of Timers to Clocks

123400 The relationship between clocks and timers armed with an absolute time is
123401 straightforward: a timer expiration signal is requested when the associated clock reaches
123402 or exceeds the specified time. The relationship between clocks and timers armed with a
123403 relative time (an interval) is less obvious, but not unintuitive. In this case, a timer
123404 expiration signal is requested when the specified interval, *as measured by the associated clock*,
123405 has passed. For the required CLOCK_REALTIME clock, this allows timer expiration
123406 signals to be requested at specified ``wall clock'' times (absolute), or when a specified
123407 interval of ``realtime'' has passed (relative). For an implementation-defined clock ‡ say a

process virtual time clock—timer expirations could be requested when the process has used a specified total amount of virtual time (absolute), or when it has used a specified *additional* amount of virtual time (relative).

The interfaces also allow flexibility in the implementation of the functions. For example, an implementation could convert all absolute times to intervals by subtracting the clock value at the time of the call from the requested expiration time and ``counting down'' at the supported resolution. Or it could convert all relative times to absolute expiration time by adding in the clock value at the time of the call and comparing the clock value to the expiration time at the supported resolution. Or it might even choose to maintain absolute times as absolute and compare them to the clock value at the supported resolution for absolute timers, and maintain relative times as intervals and count them down at the resolution supported for relative timers. The choice will be driven by efficiency considerations and the underlying hardware or software clock implementation.

Data Definitions for Clocks and Timers

POSIX.1-2017 uses a time representation capable of supporting nanosecond resolution timers for the following reasons:

- To enable POSIX.1-2017 to represent those computer systems already using nanosecond or submicrosecond resolution clocks.
- To accommodate those per-process timers that might need nanoseconds to specify an absolute value of system-wide clocks, even though the resolution of the per-process timer may only be milliseconds, or *vice versa*.
- Because the number of nanoseconds in a second can be represented in 32 bits.

Time values are represented in the **timespec** structure. The *tv_sec* member is of type **time_t** so that this member is compatible with time values used by POSIX.1 functions and the ISO C standard. The *tv_nsec* member is a **signed long** in order to simplify and clarify code that decrements or finds differences of time values. Note that because 1 billion (number of nanoseconds per second) is less than half of the value representable by a signed 32-bit value, it is always possible to add two valid fractional seconds represented as integral nanoseconds without overflowing the signed 32-bit value.

A maximum allowable resolution for the CLOCK_REALTIME clock of 20 ms (1/50 seconds) was chosen to allow line frequency clocks in European countries to be conforming. 60 Hz clocks in the US will also be conforming, as will finer granularity clocks, although a Strictly Conforming Application cannot assume a granularity of less than 20 ms (1/50 seconds).

The minimum allowable maximum time allowed for the CLOCK_REALTIME clock and the function *nanosleep*(), and timers created with *clock_id*=CLOCK_REALTIME, is determined by the fact that the *tv_sec* member is of type **time_t**.

POSIX.1-2017 specifies that timer expirations must not be delivered early, and *nanosleep*() must not return early due to quantization error. POSIX.1-2017 discusses the various implementations of *alarm*() in the rationale and states that implementations that do not allow alarm signals to occur early are the most appropriate, but refrained from mandating this behavior. Because of the importance of predictability to realtime applications, POSIX.1-2017 takes a stronger stance.

The standard developers considered using a time representation that differs from POSIX.1b in the second 32 bit of the 64-bit value. Whereas POSIX.1b defines this field as a fractional second in nanoseconds, the other methodology defines this as a binary fraction of one second, with the radix point assumed before the most significant bit.

123455 POSIX.1b is a software, source-level standard and most of the benefits of the alternate
123456 representation are enjoyed by hardware implementations of clocks and algorithms. It was
123457 felt that mandating this format for POSIX.1b clocks and timers would unnecessarily
123458 burden the application developer with writing, possibly non-portable, multiple precision
123459 arithmetic packages to perform conversion between binary fractions and integral units
123460 such as nanoseconds, milliseconds, and so on.

123461 **Rationale for the Monotonic Clock**

123462 For those applications that use time services to achieve realtime behavior, changing the value of
123463 the clock on which these services rely may cause erroneous timing behavior. For these
123464 applications, it is necessary to have a monotonic clock which cannot run backwards, and which
123465 has a maximum clock jump that is required to be documented by the implementation.
123466 Additionally, it is desirable (but not required by POSIX.1-2017) that the monotonic clock
123467 increases its value uniformly. This clock should not be affected by changes to the system time;
123468 for example, to synchronize the clock with an external source or to account for leap seconds.
123469 Such changes would cause errors in the measurement of time intervals for those time services
123470 that use the absolute value of the clock.

123471 One could argue that by defining the behavior of time services when the value of a clock is
123472 changed, deterministic realtime behavior can be achieved. For example, one could specify that
123473 relative time services should be unaffected by changes in the value of a clock. However, there are
123474 time services that are based upon an absolute time, but that are essentially intended as relative
123475 time services. For example, *pthread_cond_timedwait*() uses an absolute time to allow it to wake
123476 up after the required interval despite spurious wakeups. Although sometimes the
123477 *pthread_cond_timedwait*() timeouts are absolute in nature, there are many occasions in which they
123478 are relative, and their absolute value is determined from the current time plus a relative time
123479 interval. In this latter case, if the clock changes while the thread is waiting, the wait interval will
123480 not be the expected length. If a *pthread_cond_timedwait*() function were created that would take a
123481 relative time, it would not solve the problem because to retain the intended ``deadline'' a thread
123482 would need to compensate for latency due to the spurious wakeup, and preemption between
123483 wakeup and the next wait.

123484 The solution is to create a new monotonic clock, whose value does not change except for the
123485 regular ticking of the clock, and use this clock for implementing the various relative timeouts
123486 that appear in the different POSIX interfaces, as well as allow *pthread_cond_timedwait*() to choose
123487 this new clock for its timeout. A new *clock_nanosleep*() function is created to allow an application
123488 to take advantage of this newly defined clock. Notice that the monotonic clock may be
123489 implemented using the same hardware clock as the system clock.

123490 Relative timeouts for *sigtimedwait*() and *aio_suspend*() have been redefined to use the monotonic
123491 clock, if present. The *alarm*() function has not been redefined, because the same effect but with
123492 better resolution can be achieved by creating a timer (for which the appropriate clock may be
123493 chosen).

123494 The *pthread_cond_timedwait*() function has been treated in a different way, compared to other
123495 functions with absolute timeouts, because it is used to wait for an event, and thus it may have a
123496 deadline, while the other timeouts are generally used as an error recovery mechanism, and for
123497 them the use of the monotonic clock is not so important. Since the desired timeout for the
123498 *pthread_cond_timedwait*() function may either be a relative interval or an absolute time of day
123499 deadline, a new initialization attribute has been created for condition variables to specify the
123500 clock that is used for measuring the timeout in a call to *pthread_cond_timedwait*(). In this way, if
123501 a relative timeout is desired, the monotonic clock will be used; if an absolute deadline is
123502 required instead, the CLOCK_REALTIME or another appropriate clock may be used. This
123503 capability has not been added to other functions with absolute timeouts because for those

functions the expected use of the timeout is mostly to prevent errors, and not so often to meet precise deadlines. As a consequence, the complexity of adding this capability is not justified by its perceived application usage.

The *nanosleep*() function has not been modified with the introduction of the monotonic clock. Instead, a new *clock_nanosleep*() function has been created, in which the desired clock may be specified in the function call.

History of Resolution Issues

Due to the shift from relative to absolute timeouts in IEEE Std 1003.1d-1999, the amendments to the *sem_timedwait*(), *pthread_mutex_timedlock*(), *mq_timedreceive*(), and *mq_timedsend*() functions of that standard have been removed. Those amendments specified that CLOCK_MONOTONIC would be used for the (relative) timeouts if the Monotonic Clock option was supported.

Having these functions continue to be tied solely to CLOCK_MONOTONIC would not work. Since the absolute value of a time value obtained from CLOCK_MONOTONIC is unspecified, under the absolute timeouts interface, applications would behave differently depending on whether the Monotonic Clock option was supported or not (because the absolute value of the clock would have different meanings in either case).

Two options were considered:

1. Leave the current behavior unchanged, which specifies the CLOCK_REALTIME clock for these (absolute) timeouts, to allow portability of applications between implementations supporting or not the Monotonic Clock option.
2. Modify these functions in the way that *pthread_cond_timedwait*() was modified to allow a choice of clock, so that an application could use CLOCK_REALTIME when it is trying to achieve an absolute timeout and CLOCK_MONOTONIC when it is trying to achieve a relative timeout.

It was decided that the features of CLOCK_MONOTONIC are not as critical to these functions as they are to *pthread_cond_timedwait*(). The *pthread_cond_timedwait*() function is given a relative timeout; the timeout may represent a deadline for an event. When these functions are given relative timeouts, the timeouts are typically for error recovery purposes and need not be so precise.

Therefore, it was decided that these functions should be tied to CLOCK_REALTIME and not complicated by being given a choice of clock.

Execution Time Monitoring

Introduction

The main goals of the execution time monitoring facilities defined in this chapter are to measure the execution time of processes and threads and to allow an application to establish CPU time limits for these entities.

The analysis phase of time-critical realtime systems often relies on the measurement of execution times of individual threads or processes to determine whether the timing requirements will be met. Also, performance analysis techniques for soft deadline realtime systems rely heavily on the determination of these execution times. The execution time monitoring functions provide application developers with the ability to measure these execution times online and open the possibility of dynamic execution-time analysis and system reconfiguration, if required.

The second goal of allowing an application to establish execution time limits for individual

123549 processes or threads and detecting when they overrun allows program robustness to be
123550 increased by enabling online checking of the execution times.

123551 If errors are detected—possibly because of erroneous program constructs, the existence of
123552 errors in the analysis phase, or a burst of event arrivals—online detection and recovery is
123553 possible in a portable way. This feature can be extremely important for many time-critical
123554 applications. Other applications require trapping CPU-time errors as a normal way to exit
123555 an algorithm; for instance, some realtime artificial intelligence applications trigger a
123556 number of independent inference processes of varying accuracy and speed, limit how long
123557 they can run, and pick the best answer available when time runs out. In many periodic
123558 systems, overrun processes are simply restarted in the next resource period, after necessary
123559 end-of-period actions have been taken. This allows algorithms that are inherently data-
123560 dependent to be made predictable.

123561 The interface that appears in this chapter defines a new type of clock, the CPU-time clock,
123562 which measures execution time. Each process or thread can invoke the clock and timer
123563 functions defined in POSIX.1 to use them. Functions are also provided to access the CPU-
123564 time clock of other processes or threads to enable remote monitoring of these clocks.
123565 Monitoring of threads of other processes is not supported, since these threads are not
123566 visible from outside of their own process with the interfaces defined in POSIX.1.

123567 Execution Time Monitoring Interface

123568 The clock and timer interface defined in POSIX.1 historically only defined one clock, which
123569 measures wall-clock time. The requirements for measuring execution time of processes and
123570 threads, and setting limits to their execution time by detecting when they overrun, can be
123571 accomplished with that interface if a new kind of clock is defined. These new clocks
123572 measure execution time, and one is associated with each process and with each thread. The
123573 clock functions currently defined in POSIX.1 can be used to read and set these CPU-time
123574 clocks, and timers can be created using these clocks as their timing base. These timers can
123575 then be used to send a signal when some specified execution time has been exceeded. The
123576 CPU-time clocks of each process or thread can be accessed by using the symbols
123577 CLOCK_PROCESS_CPUTIME_ID or CLOCK_THREAD_CPUTIME_ID.

123578 The clock and timer interface defined in POSIX.1 and extended with the new kind of CPU-
123579 time clock would only allow processes or threads to access their own CPU-time clocks.
123580 However, many realtime systems require the possibility of monitoring the execution time
123581 of processes or threads from independent monitoring entities. In order to allow
123582 applications to construct independent monitoring entities that do not require cooperation
123583 from or modification of the monitored entities, two functions have been added:
123584 *clock_getcpuclockid*(), for accessing CPU-time clocks of other processes, and
123585 *pthread_getcpuclockid*(), for accessing CPU-time clocks of other threads. These functions
123586 return the clock identifier associated with the process or thread specified in the call. These
123587 clock IDs can then be used in the rest of the clock function calls.

123588 The clocks accessed through these functions could also be used as a timing base for the
123589 creation of timers, thereby allowing independent monitoring entities to limit the CPU time
123590 consumed by other entities. However, this possibility would imply additional complexity
123591 and overhead because of the need to maintain a timer queue for each process or thread, to
123592 store the different expiration times associated with timers created by different processes or
123593 threads. The working group decided this additional overhead was not justified by
123594 application requirements. Therefore, creation of timers attached to the CPU-time clocks of
123595 other processes or threads has been specified as implementation-defined.

123596 Overhead Considerations

123597 The measurement of execution time may introduce additional overhead in the thread
123598 scheduling, because of the need to keep track of the time consumed by each of these
123599 entities. In library-level implementations of threads, the efficiency of scheduling could be
123600 somehow compromised because of the need to make a kernel call, at each context switch,
123601 to read the process CPU-time clock. Consequently, a thread creation attribute called *cpu-*
123602 *clock-requirement* was defined, to allow threads to disconnect their respective CPU-time
123603 clocks. However, the Ballot Group considered that this attribute itself introduced some
123604 overhead, and that in current implementations it was not worth the effort. Therefore, the
123605 attribute was deleted, and thus thread CPU-time clocks are required for all threads if the
123606 Thread CPU-Time Clocks option is supported.

123607 Accuracy of CPU-Time Clocks

123608 The mechanism used to measure the execution time of processes and threads is specified in
123609 POSIX.1-2017 as implementation-defined. The reason for this is that both the underlying
123610 hardware and the implementation architecture have a very strong influence on the
123611 accuracy achievable for measuring CPU time. For some implementations, the specification
123612 of strict accuracy requirements would represent very large overheads, or even the
123613 impossibility of being implemented.

123614 Since the mechanism for measuring execution time is implementation-defined, realtime
123615 applications will be able to take advantage of accurate implementations using a portable
123616 interface. Of course, strictly conforming applications cannot rely on any particular degree
123617 of accuracy, in the same way as they cannot rely on a very accurate measurement of wall
123618 clock time. There will always exist applications whose accuracy or efficiency requirements
123619 on the implementation are more rigid than the values defined in POSIX.1-2017 or any
123620 other standard.

123621 In any case, there is a minimum set of characteristics that realtime applications would
123622 expect from most implementations. One such characteristic is that the sum of all the
123623 execution times of all the threads in a process equals the process execution time, when no
123624 CPU-time clocks are disabled. This need not always be the case because implementations
123625 may differ in how they account for time during context switches. Another characteristic is
123626 that the sum of the execution times of all processes in a system equals the number of
123627 processors, multiplied by the elapsed time, assuming that no processor is idle during that
123628 elapsed time. However, in some implementations it might not be possible to relate CPU
123629 time to elapsed time. For example, in a heterogeneous multi-processor system in which
123630 each processor runs at a different speed, an implementation may choose to define each
123631 ``second'' of CPU time to be a certain number of ``cycles'' that a CPU has executed.

123632 Existing Practice

123633 Measuring and limiting the execution time of each concurrent activity are common
123634 features of most industrial implementations of realtime systems. Almost all critical
123635 realtime systems are currently built upon a cyclic executive. With this approach, a regular
123636 timer interrupt kicks off the next sequence of computations. It also checks that the current
123637 sequence has completed. If it has not, then some error recovery action can be undertaken
123638 (or at least an overrun is avoided). Current software engineering principles and the
123639 increasing complexity of software are driving application developers to implement these
123640 systems on multi-threaded or multi-process operating systems. Therefore, if a POSIX
123641 operating system is to be used for this type of application, then it must offer the same level
123642 of protection.

123643 Execution time clocks are also common in most UNIX implementations, although these
123644 clocks usually have requirements different from those of realtime applications. The

123645 POSIX.1 *times*() function supports the measurement of the execution time of the calling
123646 process, and its terminated child processes. This execution time is measured in clock ticks
123647 and is supplied as two different values with the user and system execution times,
123648 respectively. BSD supports the function *getrusage*(), which allows the calling process to get
123649 information about the resources used by itself and/or all of its terminated child processes.
123650 The resource usage includes user and system CPU time. Some UNIX systems have options
123651 to specify high resolution (up to one microsecond) CPU-time clocks using the *times*() or
123652 the *getrusage*() functions.

123653 The *times*() and *getrusage*() interfaces do not meet important realtime requirements, such
123654 as the possibility of monitoring execution time from a different process or thread, or the
123655 possibility of detecting an execution time overrun. The latter requirement is supported in
123656 some UNIX implementations that are able to send a signal when the execution time of a
123657 process has exceeded some specified value. For example, BSD defines the functions
123658 *getitimer*() and *setitimer*(), which can operate either on a realtime clock (wall-clock), or on
123659 virtual-time or profile-time clocks which measure CPU time in two different ways. These
123660 functions do not support access to the execution time of other processes.

123661 The IBM MVS operating system supports per-process and per-thread execution time
123662 clocks. It also supports limiting the execution time of a given process.

123663 Given all this existing practice, the working group considered that the POSIX.1 clocks and
123664 timers interface was appropriate to meet most of the requirements that realtime
123665 applications have for execution time clocks. Functions were added to get the CPU time
123666 clock IDs, and to allow/disallow the thread CPU-time clocks (in order to preserve the
123667 efficiency of some implementations of threads).

123668 Clock Constants

123669 The definition of the manifest constants CLOCK_PROCESS_CPUTIME_ID and
123670 CLOCK_THREAD_CPUTIME_ID allows processes or threads, respectively, to access their
123671 own execution-time clocks. However, given a process or thread, access to its own
123672 execution-time clock is also possible if the clock ID of this clock is obtained through a call
123673 to *clock_getcpuclockid*() or *pthread_getcpuclockid*(). Therefore, these constants are not
123674 necessary and could be deleted to make the interface simpler. Their existence saves one
123675 system call in the first access to the CPU-time clock of each process or thread. The working
123676 group considered this issue and decided to leave the constants in POSIX.1-2017 because
123677 they are closer to the POSIX.1b use of clock identifiers.

123678 Library Implementations of Threads

123679 In library implementations of threads, kernel entities and library threads can coexist. In
123680 this case, if the CPU-time clocks are supported, most of the clock and timer functions will
123681 need to have two implementations: one in the thread library, and one in the system calls
123682 library. The main difference between these two implementations is that the thread library
123683 implementation will have to deal with clocks and timers that reside in the thread space,
123684 while the kernel implementation will operate on timers and clocks that reside in kernel
123685 space. In the library implementation, if the clock ID refers to a clock that resides in the
123686 kernel, a kernel call will have to be made. The correct version of the function can be chosen
123687 by specifying the appropriate order for the libraries during the link process.

123688 History of Resolution Issues: Deletion of the *enable* Attribute

123689 In early proposals, consideration was given to inclusion of an attribute called *enable* for
123690 CPU-time clocks. This would allow implementations to avoid the overhead of measuring
123691 execution time for those processes or threads for which this measurement was not
123692 required. However, this is unnecessary since processes are already required to measure

123693 execution time by the POSIX.1 *times*() function. Consequently, the *enable* attribute is not
123694 present.

123695 **Rationale Relating to Timeouts**

123696 Requirements for Timeouts

123697 Realtime systems which must operate reliably over extended periods without human
123698 intervention are characteristic in embedded applications such as avionics, machine control,
123699 and space exploration, as well as more mundane applications such as cable TV, security
123700 systems, and plant automation. A multi-tasking paradigm, in which many independent
123701 and/or cooperating software functions relinquish the processor(s) while waiting for a
123702 specific stimulus, resource, condition, or operation completion, is very useful in producing
123703 well engineered programs for such systems. For such systems to be robust and fault-
123704 tolerant, expected occurrences that are unduly delayed or that never occur must be
123705 detected so that appropriate recovery actions may be taken. This is difficult if there is no
123706 way for a task to regain control of a processor once it has relinquished control (blocked)
123707 awaiting an occurrence which, perhaps because of corrupted code, hardware malfunction,
123708 or latent software bugs, will not happen when expected. Therefore, the common practice
123709 in realtime operating systems is to provide a capability to time out such blocking services.
123710 Although there are several methods to achieve this already defined by POSIX, none are as
123711 reliable or efficient as initiating a timeout simultaneously with initiating a blocking service.
123712 This is especially critical in hard-realtime embedded systems because the processors
123713 typically have little time reserve, and allowed fault recovery times are measured in
123714 milliseconds rather than seconds.

123715 The working group largely agreed that such timeouts were necessary and ought to become
123716 part of POSIX.1-2017, particularly vendors of realtime operating systems whose customers
123717 had already expressed a strong need for timeouts. There was some resistance to inclusion
123718 of timeouts in POSIX.1-2017 because the desired effect, fault tolerance, could, in theory, be
123719 achieved using existing facilities and alternative software designs, but there was no
123720 compelling evidence that realtime system designers would embrace such designs at the
123721 sacrifice of performance and/or simplicity.

123722 Which Services should be Timed Out?

123723 Originally, the working group considered the prospect of providing timeouts on all
123724 blocking services, including those currently existing in POSIX.1, POSIX.1b, and POSIX.1c,
123725 and future interfaces to be defined by other working groups, as sort of a general policy.
123726 This was rather quickly rejected because of the scope of such a change, and the fact that
123727 many of those services would not normally be used in a realtime context. More traditional
123728 timesharing solutions to timeout would suffice for most of the POSIX.1 interfaces, while
123729 others had asynchronous alternatives which, while more complex to utilize, would be
123730 adequate for some realtime and all non-realtime applications.

123731 The list of potential candidates for timeouts was narrowed to the following for further
123732 consideration:

123733 ‡ OSPIX.1b

123734 ‡ *sem_wait*()

123735 ‡ *mq_receive*()

123736 ‡ *mq_send*()

- *lio_listio*()
- *aio_suspend*()
- *sigwait*() (timeout already implemented by *sigtimedwait*())

- POSIX.1c
  - *pthread_mutex_lock*()
  - *pthread_join*()
  - *pthread_cond_wait*()
    (timeout already implemented by *pthread_cond_timedwait*())

- POSIX.1
  - *read*()
  - *write*()

After further review by the working group, the *lio_listio*(), *read*(), and *write*() functions (all forms of blocking synchronous I/O) were eliminated from the list because of the following:

- Asynchronous alternatives exist
- Timeouts can be implemented, albeit non-portably, in device drivers
- Strong desire not to introduce modifications to POSIX.1 interfaces

The working group ultimately rejected *pthread_join*() since both that interface and a timed variant of that interface are non-minimal and may be implemented as a function. See below for a library implementation of *pthread_join*().

Thus, there was a consensus among the working group members to add timeouts to 4 of the remaining 5 functions (the timeout for *aio_suspend*() was ultimately added directly to POSIX.1b, while the others were added by POSIX.1d). However, *pthread_mutex_lock*() remained contentious.

Many feel that *pthread_mutex_lock*() falls into the same class as the other functions; that is, it is desirable to time out a mutex lock because a mutex may fail to be unlocked due to errant or corrupted code in a critical section (looping or branching outside of the unlock code), and therefore is equally in need of a reliable, simple, and efficient timeout. In fact, since mutexes are intended to guard small critical sections, most *pthread_mutex_lock*() calls would be expected to obtain the lock without blocking nor utilizing any kernel service, even in implementations of threads with global contention scope; the timeout alternative need only be considered after it is determined that the thread must block.

Those opposed to timing out mutexes feel that the very simplicity of the mutex is compromised by adding a timeout semantic, and that to do so is senseless. They claim that if a timed mutex is really deemed useful by a particular application, then it can be constructed from the facilities already in POSIX.1b and POSIX.1c. The following two C-language library implementations of mutex locking with timeout represent the solutions offered (in both implementations, the timeout parameter is specified as absolute time, not relative time as in the proposed POSIX.1c interfaces).

Spinlock Implementation

```
#include <pthread.h>
#include <time.h>
#include <errno.h>

int pthread_mutex_timedlock(pthread_mutex_t *mutex,
        const struct timespec *timeout)
    {
    struct timespec timenow;

    while (pthread_mutex_trylock(mutex) == EBUSY)
        {
        clock_gettime(CLOCK_REALTIME, &timenow);
        if (timespec_cmp(&timenow,timeout) >= 0)
            {
            return ETIMEDOUT;
        }
        pthread_yield();
        }
    return 0;
    }
```

The Spinlock implementation is generally unsuitable for any application using priority-based thread scheduling policies such as SCHED_FIFO or SCHED_RR, since the mutex could currently be held by a thread of lower priority within the same allocation domain, but since the waiting thread never blocks, only threads of equal or higher priority will ever run, and the mutex cannot be unlocked. Setting priority inheritance or priority ceiling protocol on the mutex does not solve this problem, since the priority of a mutex owning thread is only boosted if higher priority threads are blocked waiting for the mutex; clearly not the case for this spinlock.

Condition Wait Implementation

```
#include <pthread.h>
#include <time.h>
#include <errno.h>

struct timed_mutex
    {
    int locked;
    pthread_mutex_t mutex;
    pthread_cond_t cond;
    };
typedef struct timed_mutex timed_mutex_t;

int timed_mutex_lock(timed_mutex_t *tm,
        const struct timespec *timeout)
    {
    int timedout=FALSE;
    int error_status;

    pthread_mutex_lock(&tm->mutex);

    while (tm->locked && !timedout)
        {
        if ((error_status=pthread_cond_timedwait(&tm->cond,
            &tm->mutex,
```

```
                    timeout))!=0)
                {
                if (error_status==ETIMEDOUT) timedout = TRUE;
                }
            }

            if(timedout)
                {
                pthread_mutex_unlock(&tm->mutex);
                return ETIMEDOUT;
                }
            else
                {
                tm->locked = TRUE;
                pthread_mutex_unlock(&tm->mutex);
                return 0;
                }
            }

        void timed_mutex_unlock(timed_mutex_t *tm)
            {
            pthread_mutex_lock(&tm->mutex); / for case assignment not atomic /
            tm->locked = FALSE;
            pthread_mutex_unlock(&tm->mutex);
            pthread_cond_signal(&tm->cond);
            }
```

The Condition Wait implementation effectively substitutes the *pthread_cond_timedwait*() function (which is currently timed out) for the desired *pthread_mutex_timedlock*(). Since waits on condition variables currently do not include protocols which avoid priority inversion, this method is generally unsuitable for realtime applications because it does not provide the same priority inversion protection as the untimed *pthread_mutex_lock*(). Also, for any given implementations of the current mutex and condition variable primitives, this library implementation has a performance cost at least 2.5 times that of the untimed *pthread_mutex_lock*() even in the case where the timed mutex is readily locked without blocking (the interfaces required for this case are shown in bold). Even in uniprocessors or where assignment is atomic, at least an additional *pthread_cond_signal*() is required. *pthread_mutex_timedlock*() could be implemented at effectively no performance penalty in this case because the timeout parameters need only be considered after it is determined that the mutex cannot be locked immediately.

Thus it has not yet been shown that the full semantics of mutex locking with timeout can be efficiently and reliably achieved using existing interfaces. Even if the existence of an acceptable library implementation were proven, it is difficult to justify why the interface itself should not be made portable, especially considering approval for the other four timeouts.

Rationale for Library Implementation of *pthread_timedjoin*()

Library implementation of *pthread_timedjoin*():

```
/*
 * Construct a thread variety entirely from existing functions
 * with which a join can be done, allowing the join to time out.
 */
#include <pthread.h>
```

```
#include <time.h>

struct timed_thread {
    pthread_t t;
    pthread_mutex_t m;
    int exiting;
    pthread_cond_t exit_c;
    void *(*start_routine)(void *arg);
    void *arg;
    void *status;
};

typedef struct timed_thread *timed_thread_t;
static pthread_key_t timed_thread_key;
static pthread_once_t timed_thread_once = PTHREAD_ONCE_INIT;

static void timed_thread_init()
{
    pthread_key_create(&timed_thread_key, NULL);
}

static void *timed_thread_start_routine(void *args)

/*
 * Routine to establish thread-specific data value and run the actual
 * thread start routine which was supplied to timed_thread_create().
 */
{
    timed_thread_t tt = (timed_thread_t) args;

    pthread_once(&timed_thread_once, timed_thread_init);
    pthread_setspecific(timed_thread_key, (void *)tt);
    timed_thread_exit((tt->start_routine)(tt->arg));
}

int timed_thread_create(timed_thread_t ttp, const pthread_attr_t *attr,
    void *(*start_routine)(void *), void *arg)

/*
 * Allocate a thread which can be used with timed_thread_join().
 */
{
    timed_thread_t tt;
    int result;

    tt = (timed_thread_t) malloc(sizeof(struct timed_thread));
    pthread_mutex_init(&tt->m,NULL);
    tt->exiting = FALSE;
    pthread_cond_init(&tt->exit_c,NULL);
    tt->start_routine = start_routine;
    tt->arg = arg;
    tt->status = NULL;

    if ((result = pthread_create(&tt->t, attr,
        timed_thread_start_routine, (void *)tt)) != 0) {
        free(tt);
        return result;
    }
```

```
123921              pthread_detach(tt->t);
123922              ttp = tt;
123923              return 0;
123924          }
123925          int timed_thread_join(timed_thread_t tt,
123926              struct timespec *timeout,
123927              void **status)
123928          {
123929              int result;
123930              pthread_mutex_lock(&tt->m);
123931              result = 0;
123932              /*
123933               * Wait until the thread announces that it is exiting,
123934               * or until timeout.
123935               */
123936              while (result == 0 && ! tt->exiting) {
123937                  result = pthread_cond_timedwait(&tt->exit_c, &tt->m, timeout);
123938              }
123939              pthread_mutex_unlock(&tt->m);
123940              if (result == 0 && tt->exiting) {
123941                  *status = tt->status;
123942                  free((void *)tt);
123943                  return result;
123944              }
123945              return result;
123946          }
123947          void timed_thread_exit(void *status)
123948          {
123949              timed_thread_t tt;
123950              void *specific;
123951              if ((specific=pthread_getspecific(timed_thread_key)) == NULL){
123952                  /*
123953                   * Handle cases which will not happen with correct usage.
123954                   */
123955                  pthread_exit( NULL);
123956              }
123957              tt = (timed_thread_t) specific;
123958              pthread_mutex_lock(&tt->m);
123959              /*
123960               * Tell a joiner that we are exiting.
123961               */
123962              tt->status = status;
123963              tt->exiting = TRUE;
123964              pthread_cond_signal(&tt->exit_c);
123965              pthread_mutex_unlock(&tt->m);
123966              /*
123967               * Call pthread exit() to call destructors and really
123968               * exit the thread.
123969               */
123970              pthread_exit(NULL);
123971          }
```

The *pthread_join*() C-language example shown above demonstrates that it is possible, using existing pthread facilities, to construct a variety of thread which allows for joining such a thread, but which allows the join operation to time out. It does this by using a *pthread_cond_timedwait*() to wait for the thread to exit. A **timed_thread_t** descriptor structure is used to pass parameters from the creating thread to the created thread, and from the exiting thread to the joining thread. This implementation is roughly equivalent to what a normal *pthread_join*() implementation would do, with the single change being that *pthread_cond_timedwait*() is used in place of a simple *pthread_cond_wait*().

Since it is possible to implement such a facility entirely from existing pthread interfaces, and with roughly equal efficiency and complexity to an implementation which would be provided directly by a pthreads implementation, it was the consensus of the working group members that any *pthread_timedjoin*() facility would be unnecessary, and should not be provided.

Form of the Timeout Interfaces

The working group considered a number of alternative ways to add timeouts to blocking services. At first, a system interface which would specify a one-shot or persistent timeout to be applied to subsequent blocking services invoked by the calling process or thread was considered because it allowed all blocking services to be timed out in a uniform manner with a single additional interface; this was rather quickly rejected because it could easily result in the wrong services being timed out.

It was suggested that a timeout value might be specified as an attribute of the object (semaphore, mutex, message queue, and so on), but there was no consensus on this, either on a case-by-case basis or for all timeouts.

Looking at the two existing timeouts for blocking services indicates that the working group members favor a separate interface for the timed version of a function. However, *pthread_cond_timedwait*() utilizes an absolute timeout value while *sigtimedwait*() uses a relative timeout value. The working group members agreed that relative timeout values are appropriate where the timeout mechanism's primary use was to deal with an unexpected or error situation, but they are inappropriate when the timeout must expire at a particular time, or before a specific deadline. For the timeouts being introduced in POSIX.1-2017, the working group considered allowing both relative and absolute timeouts as is done with POSIX.1b timers, but ultimately favored the simpler absolute timeout form.

An absolute time measure can be easily implemented on top of an interface that specifies relative time, by reading the clock, calculating the difference between the current time and the desired wakeup time, and issuing a relative timeout call. But there is a race condition with this approach because the thread could be preempted after reading the clock, but before making the timed-out call; in this case, the thread would be awakened later than it should and, thus, if the wakeup time represented a deadline, it would miss it.

There is also a race condition when trying to build a relative timeout on top of an interface that specifies absolute timeouts. In this case, the clock would have to be read to calculate the absolute wakeup time as the sum of the current time plus the relative timeout interval. In this case, if the thread is preempted after reading the clock but before making the timed-out call, the thread would be awakened earlier than desired.

But the race condition with the absolute timeouts interface is not as bad as the one that happens with the relative timeout interface, because there are simple workarounds. For the absolute timeouts interface, if the timing requirement is a deadline, the deadline can still be met because the thread woke up earlier than the deadline. If the timeout is just used as an error recovery mechanism, the precision of timing is not really important. If the timing requirement is that between actions A and B a minimum interval of time must elapse, the

absolute timeout interface can be safely used by reading the clock after action A has been started. It could be argued that, since the call with the absolute timeout is atomic from the application point of view, it is not possible to read the clock after action A, if this action is part of the timed-out call. But looking at the nature of the calls for which timeouts are specified (locking a mutex, waiting for a semaphore, waiting for a message, or waiting until there is space in a message queue), the timeouts that an application would build on these actions would not be triggered by these actions themselves, but by some other external action. For example, if waiting for a message to arrive to a message queue, and waiting for at least 20 milliseconds, this time interval would start to be counted from some event that would trigger both the action that produces the message, as well as the action that waits for the message to arrive, and not by the wait-for-message operation itself. In this case, the workaround proposed above could be used.

For these reasons, the absolute timeout is preferred over the relative timeout interface.

B.2.9 Threads

Threads will normally be more expensive than subroutines (or functions, routines, and so on) if specialized hardware support is not provided. Nevertheless, threads should be sufficiently efficient to encourage their use as a medium to fine-grained structuring mechanism for parallelism in an application. Structuring an application using threads then allows it to take immediate advantage of any underlying parallelism available in the host environment. This means implementors are encouraged to optimize for fast execution at the possible expense of efficient utilization of storage. For example, a common thread creation technique is to cache appropriate thread data structures. That is, rather than releasing system resources, the implementation retains these resources and reuses them when the program next asks to create a new thread. If this reuse of thread resources is to be possible, there has to be very little unique state associated with each thread, because any such state has to be reset when the thread is reused.

Thread Creation Attributes

Attributes objects are provided for threads, mutexes, and condition variables as a mechanism to support probable future standardization in these areas without requiring that the interface itself be changed.

Attributes objects provide clean isolation of the configurable aspects of threads. For example, ``stack size'' is an important attribute of a thread, but it cannot be expressed portably. When porting a threaded program, stack sizes often need to be adjusted. The use of attributes objects can help by allowing the changes to be isolated in a single place, rather than being spread across every instance of thread creation.

Attributes objects can be used to set up *classes* of threads with similar attributes; for example, ``threads with large stacks and high priority'' or ``threads with minimal stacks''. These classes can be defined in a single place and then referenced wherever threads need to be created. Changes to ``class'' decisions become straightforward, and detailed analysis of each *pthread_create*( ) call is not required.

The attributes objects are defined as opaque types as an aid to extensibility. If these objects had been specified as structures, adding new attributes would force recompilation of all multi-threaded programs when the attributes objects are extended; this might not be possible if different program components were supplied by different vendors.

Additionally, opaque attributes objects present opportunities for improving performance. Argument validity can be checked once when attributes are set, rather than each time a thread is

created. Implementations will often need to cache kernel objects that are expensive to create. Opaque attributes objects provide an efficient mechanism to detect when cached objects become invalid due to attribute changes.

Because assignment is not necessarily defined on a given opaque type, implementation-defined default values cannot be defined in a portable way. The solution to this problem is to allow attribute objects to be initialized dynamically by attributes object initialization functions, so that default values can be supplied automatically by the implementation.

The following proposal was provided as a suggested alternative to the supplied attributes:

1. Maintain the style of passing a parameter formed by the bitwise-inclusive OR of flags to the initialization routines (*pthread_create*(), *pthread_mutex_init*(), *pthread_cond_init*()). The parameter containing the flags should be an opaque type for extensibility. If no flags are set in the parameter, then the objects are created with default characteristics. An implementation may specify implementation-defined flag values and associated behavior.

2. If further specialization of mutexes and condition variables is necessary, implementations may specify additional procedures that operate on the **pthread_mutex_t** and **pthread_cond_t** objects (instead of on attributes objects).

The difficulties with this solution are:

1. A bitmask is not opaque if bits have to be set into bit-vector attributes objects using explicitly-coded bitwise-inclusive OR operations. If the set of options exceeds an **int**, application programmers need to know the location of each bit. If bits are set or read by encapsulation (that is, *get**() or *set**() functions), then the bitmask is merely an implementation of attributes objects as currently defined and should not be exposed to the programmer.

2. Many attributes are not Boolean or very small integral values. For example, scheduling policy may be placed in 3 bits or 4 bits, but priority requires 5 bits or more, thereby taking up at least 8 bits out of a possible 16 bits on machines with 16-bit integers. Because of this, the bitmask can only reasonably control whether particular attributes are set or not, and it cannot serve as the repository of the value itself. The value needs to be specified as a function parameter (which is non-extensible), or by setting a structure field (which is non-opaque), or by *get**() and *set**() functions (making the bitmask a redundant addition to the attributes objects).

Stack size is defined as an optional attribute because the very notion of a stack is inherently machine-dependent. Some implementations may not be able to change the size of the stack, for example, and others may not need to because stack pages may be discontiguous and can be allocated and released on demand.

The attribute mechanism has been designed in large measure for extensibility. Future extensions to the attribute mechanism or to any attributes object defined in POSIX.1-2017 have to be done with care so as not to affect binary-compatibility.

Attribute objects, even if allocated by means of dynamic allocation functions such as *malloc*(), may have their size fixed at compile time. This means, for example, a *pthread_create*() in an implementation with extensions to the **pthread_attr_t** cannot look beyond the area that the binary application assumes is valid. This suggests that implementations should maintain a size field in the attributes object, as well as possibly version information, if extensions in different directions (possibly by different vendors) are to be accommodated.

124112 **Thread Implementation Models**

124113 There are various thread implementation models. At one end of the spectrum is the ``library-
124114 thread model''. In such a model, the threads of a process are not visible to the operating system
124115 kernel, and the threads are not kernel-scheduled entities. The process is the only kernel-
124116 scheduled entity. The process is scheduled onto the processor by the kernel according to the
124117 scheduling attributes of the process. The threads are scheduled onto the single kernel-scheduled
124118 entity (the process) by the runtime library according to the scheduling attributes of the threads.
124119 A problem with this model is that it constrains concurrency. Since there is only one kernel-
124120 scheduled entity (namely, the process), only one thread per process can execute at a time. If the
124121 thread that is executing blocks on I/O, then the whole process blocks.

124122 At the other end of the spectrum is the ``kernel-thread model''. In this model, all threads are
124123 visible to the operating system kernel. Thus, all threads are kernel-scheduled entities, and all
124124 threads can concurrently execute. The threads are scheduled onto processors by the kernel
124125 according to the scheduling attributes of the threads. The drawback to this model is that the
124126 creation and management of the threads entails operating system calls, as opposed to subroutine
124127 calls, which makes kernel threads heavier weight than library threads.

124128 Hybrids of these two models are common. A hybrid model offers the speed of library threads
124129 and the concurrency of kernel threads. In hybrid models, a process has some (relatively small)
124130 number of kernel scheduled entities associated with it. It also has a potentially much larger
124131 number of library threads associated with it. Some library threads may be bound to kernel-
124132 scheduled entities, while the other library threads are multiplexed onto the remaining kernel-
124133 scheduled entities. There are two levels of thread scheduling:

124134 1. The runtime library manages the scheduling of (unbound) library threads onto kernel-
124135 scheduled entities.

124136 2. The kernel manages the scheduling of kernel-scheduled entities onto processors.

124137 For this reason, a hybrid model is referred to as a two-level threads scheduling model. In this
124138 model, the process can have multiple concurrently executing threads; specifically, it can have as
124139 many concurrently executing threads as it has kernel-scheduled entities.

124140 **Thread-Specific Data**

124141 Many applications require that a certain amount of context be maintained on a per-thread basis
124142 across procedure calls. A common example is a multi-threaded library routine that allocates
124143 resources from a common pool and maintains an active resource list for each thread. The thread-
124144 specific data interface provided to meet these needs may be viewed as a two-dimensional array
124145 of values with keys serving as the row index and thread IDs as the column index (although the
124146 implementation need not work this way).

124147 Models

124148 Three possible thread-specific data models were considered:

124149 1. No Explicit Support

124150 A standard thread-specific data interface is not strictly necessary to support
124151 applications that require per-thread context. One could, for example, provide a hash
124152 function that converted a **pthread_t** into an integer value that could then be used to
124153 index into a global array of per-thread data pointers. This hash function, in
124154 conjunction with *pthread_self*( ), would be all the interface required to support a
124155 mechanism of this sort. Unfortunately, this technique is cumbersome. It can lead to
124156 duplicated code as each set of cooperating modules implements their own per-
124157 thread data management schemes. This technique would also require that **pthread_t**

not be an opaque type.

2. Single (**void** *) Pointer

   Another technique would be to provide a single word of per-thread storage and a pair of functions to fetch and store the value of this word. The word could then hold a pointer to a block of per-thread memory. The allocation, partitioning, and general use of this memory would be entirely up to the application. Although this method is not as problematic as technique 1, it suffers from interoperability problems. For example, all modules using the per-thread pointer would have to agree on a common usage protocol.

3. Key/Value Mechanism

   This method associates an opaque key (for example, stored in a variable of type **pthread_key_t**) with each per-thread datum. These keys play the role of identifiers for per-thread data. This technique is the most generic and avoids the problems noted above, albeit at the cost of some complexity.

The primary advantage of the third model is its information hiding properties. Modules using this model are free to create and use their own key(s) independent of all other such usage, whereas the other models require that all modules that use thread-specific context explicitly cooperate with all other such modules. The data-independence provided by the third model is worth the additional interface. Therefore, the third model was chosen.

Requirements

It is important that it be possible to implement the thread-specific data interface without the use of thread private memory. To do otherwise would increase the weight of each thread, thereby limiting the range of applications for which the threads interfaces provided by POSIX.1-2017 is appropriate.

The values that one binds to the key via *pthread_setspecific*() may, in fact, be pointers to shared storage locations available to all threads. It is only the key/value bindings that are maintained on a per-thread basis, and these can be kept in any portion of the address space that is reserved for use by the calling thread (for example, on the stack). Thus, no per-thread MMU state is required to implement the interface. On the other hand, there is nothing in the interface specification to preclude the use of a per-thread MMU state if it is available (for example, the key values returned by *pthread_key_create*() could be thread private memory addresses).

Standardization Issues

Thread-specific data is a requirement for a usable thread interface. The binding described in this section provides a portable thread-specific data mechanism for languages that do not directly support a thread-specific storage class. A binding to POSIX.1-2017 for a language that does include such a storage class need not provide this specific interface.

If a language were to include the notion of thread-specific storage, it would be desirable (but *not* required) to provide an implementation of the pthreads thread-specific data interface based on the language feature. For example, assume that a compiler for a C-like language supports a *private* storage class that provides thread-specific storage. Something similar to the following macros might be used to effect a compatible implementation:

```
#define pthread_key_t                   private void *
#define pthread_key_create(key)         /* no-op */
#define pthread_setspecific(key,value)  (key)=(value)
#define pthread_getspecific(key)        (key)
```

Note: For the sake of clarity, this example ignores destructor functions. A correct implementation would have to support them.

Barriers

Background

Barriers are typically used in parallel DO/FOR loops to ensure that all threads have reached a particular stage in a parallel computation before allowing any to proceed to the next stage. Highly efficient implementation is possible on machines which support a ``Fetch and Add'' operation as described in the referenced Almasi and Gottlieb (1989).

The use of return value PTHREAD_BARRIER_SERIAL_THREAD is shown in the following example:

```
if ( (status=pthread_barrier_wait(&barrier)) ==
    PTHREAD_BARRIER_SERIAL_THREAD) {
    ...serial section
    }
        else if (status != 0) {
        ...error processing
    }
status=pthread_barrier_wait(&barrier);
...
```

This behavior allows a serial section of code to be executed by one thread as soon as all threads reach the first barrier. The second barrier prevents the other threads from proceeding until the serial section being executed by the one thread has completed.

Although barriers can be implemented with mutexes and condition variables, the referenced Almasi and Gottlieb (1989) provides ample illustration that such implementations are significantly less efficient than is possible. While the relative efficiency of barriers may well vary by implementation, it is important that they be recognized in the POSIX.1-2017 to facilitate applications portability while providing the necessary freedom to implementors.

Lack of Timeout Feature

Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for barrier waits for the following reasons:

Multiple threads may use different timeout values, some of which may be indefinite. It is not clear which threads should break through the barrier with a timeout error if and when these timeouts expire.

The barrier may become unusable once a thread breaks out of a *pthread_barrier_wait*() with a timeout error. There is, in general, no way to guarantee the consistency of a barrier's internal data structures once a thread has timed out of a *pthread_barrier_wait*(). Even the inclusion of a special barrier reinitialization function would not help much since it is not clear how this function would affect the behavior of threads that reach the barrier between the original timeout and the call to the reinitialization function.

124246 **Spin Locks**

124247 Background

124248 Spin locks represent an extremely low-level synchronization mechanism suitable primarily
124249 for use on shared memory multi-processors. It is typically an atomically modified Boolean
124250 value that is set to one when the lock is held and to zero when the lock is freed.

124251 When a caller requests a spin lock that is already held, it typically spins in a loop testing
124252 whether the lock has become available. Such spinning wastes processor cycles so the lock
124253 should only be held for short durations and not across sleep/block operations. Callers
124254 should unlock spin locks before calling sleep operations.

124255 Spin locks are available on a variety of systems. The functions included in POSIX.1-2017
124256 are an attempt to standardize that existing practice.

124257 Lack of Timeout Feature

124258 Alternate versions of most blocking routines have been provided to support watchdog
124259 timeouts. No alternate interface of this sort has been provided for spin locks for the
124260 following reasons:

124261 It is impossible to determine appropriate timeout intervals for spin locks in a
124262 portable manner. The amount of time one can expect to spend spin-waiting is
124263 inversely proportional to the degree of parallelism provided by the system.

124264 It can vary from a few cycles when each competing thread is running on its own
124265 processor, to an indefinite amount of time when all threads are multiplexed on a
124266 single processor (which is why spin locking is not advisable on uniprocessors).

124267 When used properly, the amount of time the calling thread spends waiting on a spin
124268 lock should be considerably less than the time required to set up a corresponding
124269 watchdog timer. Since the primary purpose of spin locks is to provide a low-
124270 overhead synchronization mechanism for multi-processors, the overhead of a
124271 timeout mechanism was deemed unacceptable.

124272 It was also suggested that an additional *count* argument be provided (on the
124273 *pthread_spin_lock*() call) in *lieu* of a true timeout so that a spin lock call could fail gracefully
124274 if it was unable to apply the lock after *count* attempts. This idea was rejected because it is
124275 not existing practice. Furthermore, the same effect can be obtained with
124276 *pthread_spin_trylock*(), as illustrated below:

```
124277 int n = MAX_SPIN;
124278 while ( --n >= 0 )
124279 {
124280     if ( !pthread_spin_try_lock(...) )
124281         break;
124282 }
124283 if ( n >= 0 )
124284 {
124285     /* Successfully acquired the lock */
124286 }
124287 else
124288 {
124289     /* Unable to acquire the lock */
124290 }
```

124291 *process-shared* Attribute

124292 The initialization functions associated with most POSIX synchronization objects (for
124293 example, mutexes, barriers, and read-write locks) take an attributes object with a *process-*
124294 *shared* attribute that specifies whether or not the object is to be shared across processes. In
124295 the draft corresponding to the first balloting round, two separate initialization functions
124296 are provided for spin locks, however: one for spin locks that were to be shared across
124297 processes (*spin_init*()), and one for locks that were only used by multiple threads within a
124298 single process (*pthread_spin_init*()). This was done so as to keep the overhead associated
124299 with spin waiting to an absolute minimum. However, the balloting group requested that,
124300 since the overhead associated to a bit check was small, spin locks should be consistent with
124301 the rest of the synchronization primitives, and thus the *process-shared* attribute was
124302 introduced for spin locks.

124303 Spin Locks *versus* Mutexes

124304 It has been suggested that mutexes are an adequate synchronization mechanism and spin
124305 locks are not necessary. Locking mechanisms typically must trade off the processor
124306 resources consumed while setting up to block the thread and the processor resources
124307 consumed by the thread while it is blocked. Spin locks require very little resources to set
124308 up the blocking of a thread. Existing practice is to simply loop, repeating the atomic
124309 locking operation until the lock is available. While the resources consumed to set up
124310 blocking of the thread are low, the thread continues to consume processor resources while
124311 it is waiting.

124312 On the other hand, mutexes may be implemented such that the processor resources
124313 consumed to block the thread are large relative to a spin lock. After detecting that the
124314 mutex lock is not available, the thread must alter its scheduling state, add itself to a set of
124315 waiting threads, and, when the lock becomes available again, undo all of this before taking
124316 over ownership of the mutex. However, while a thread is blocked by a mutex, no processor
124317 resources are consumed.

124318 Therefore, spin locks and mutexes may be implemented to have different characteristics.
124319 Spin locks may have lower overall overhead for very short-term blocking, and mutexes
124320 may have lower overall overhead when a thread will be blocked for longer periods of time.
124321 The presence of both interfaces allows implementations with these two different
124322 characteristics, both of which may be useful to a particular application.

124323 It has also been suggested that applications can build their own spin locks from the
124324 *pthread_mutex_trylock*() function:

124325 ```
while (pthread_mutex_trylock(&mutex));
```

124326 The apparent simplicity of this construct is somewhat deceiving, however. While the actual
124327 wait is quite efficient, various guarantees on the integrity of mutex objects (for example,
124328 priority inheritance rules) may add overhead to the successful path of the trylock
124329 operation that is not required of spin locks. One could, of course, add an attribute to the
124330 mutex to bypass such overhead, but the very act of finding and testing this attribute
124331 represents more overhead than is found in the typical spin lock.

124332 The need to hold spin lock overhead to an absolute minimum also makes it impossible to
124333 provide guarantees against starvation similar to those provided for mutexes or read-write
124334 locks. The overhead required to implement such guarantees (for example, disabling
124335 preemption before spinning) may well exceed the overhead of the spin wait itself by many
124336 orders of magnitude. If a ``safe'' spin wait seems desirable, it can always be provided
124337 (albeit at some performance cost) via appropriate mutex attributes.

  
```

Robust Mutexes

Robust mutexes are intended to protect applications that use mutexes to protect data shared between different processes. If a process is terminated by a signal while a thread is holding a mutex, there is no chance for the process to clean up after it. Waiters for the locked mutex might wait indefinitely.

With robust mutexes the problem can be solved: whenever a fatal signal terminates a process, current or future waiters of the mutex are notified about this fact. The locking function provides notification of this condition through the error condition [EOWNERDEAD]. A thread then has the chance to clean up the state protected by the mutex and mark the state as consistent again by a call to *pthread_mutex_consistent*( ).

Pre-existing implementations have used the semantics of robust mutexes for a variety of situations, some of them not defined in the standard. Where a normally terminated process (i.e., when one thread calls *exit*( )) causes notification of other waiters of robust mutexes if the mutex is locked by any thread in the process. This behavior is defined in the standard and makes sense because no thread other than the thread calling *exit*( ) has the chance to clean up its data.

If a thread is terminated by cancellation or if it calls *pthread_exit*( ), the situation is different. In both these situations the thread has the chance to clean up after itself by registering appropriate cleanup handlers. There is no real reason to demand that other waiters for a robust mutex the terminating thread owns are notified. The committee felt that this is actively encouraging bad practice because programmers are tempted to rely on the robust mutex semantics instead of correctly cleaning up after themselves.

Therefore, the standard does not require notification of other waiters at the time a thread is terminated while the process continues to run. The mutex is still recognized as being locked by the process (with the thread gone it makes no sense to refer to the thread owning the mutex). Therefore, a terminating process will cause notifications about the dead owner to be sent to all waiters. This delay in the notification is not required, but programmers cannot rely on prompt notification after a thread is terminated.

For the same reason is it not required that an implementation supports robust mutexes that are not shared between processes. If a robust mutex is used only within one process, all the cleanup can be performed by the threads themselves by registering appropriate cleanup handlers. Fatal signals are of no importance in this case because after the signal is delivered there is no thread remaining to use the mutex.

Some implementations might choose to support intra-process robust mutexes and they might also send notification of a dead owner right after the previous owner died. But applications must not rely on this. Applications should only use robust mutexes for the purpose of handling fatal signals in situations where inter-process mutexes are in use.

Supported Threads Functions

On POSIX-conforming systems, the following symbolic constants are always conforming:

_POSIX_READER_WRITER_LOCKS
_POSIX_THREADS

Therefore, the following threads functions are always supported:

pthread_atfork()
pthread_attr_destroy()
pthread_attr_getdetachstate()
pthread_attr_getguardsize()
pthread_attr_getschedparam()
pthread_attr_init()
pthread_attr_setdetachstate()
pthread_attr_setguardsize()
pthread_attr_setschedparam()
pthread_cancel()
pthread_cleanup_pop()
pthread_cleanup_push()
pthread_cond_broadcast()
pthread_cond_destroy()
pthread_cond_init()
pthread_cond_signal()
pthread_cond_timedwait()
pthread_cond_wait()
pthread_condattr_destroy()
pthread_condattr_getpshared()
pthread_condattr_init()
pthread_condattr_setpshared()
pthread_create()
pthread_detach()
pthread_equal()
pthread_exit()
pthread_getconcurrency()
pthread_getspecific()
pthread_join()
pthread_key_create()
pthread_key_delete()
pthread_kill()
pthread_mutex_destroy()
pthread_mutex_init()
pthread_mutex_lock()
pthread_mutex_trylock()
pthread_mutex_unlock()
pthread_mutexattr_destroy()
pthread_mutexattr_getpshared()
pthread_mutexattr_gettype()
pthread_mutexattr_init()
pthread_mutexattr_setpshared()
pthread_mutexattr_settype()
pthread_once()
pthread_rwlock_destroy()
pthread_rwlock_init()
pthread_rwlock_rdlock()
pthread_rwlock_tryrdlock()
pthread_rwlock_trywrlock()
pthread_rwlock_unlock()
pthread_rwlock_wrlock()
pthread_rwlockattr_destroy()
pthread_rwlockattr_getpshared()
pthread_rwlockattr_init()
pthread_rwlockattr_setpshared()
pthread_self()
pthread_setcancelstate()
pthread_setcanceltype()
pthread_setconcurrency()
pthread_setspecific()
pthread_sigmask()
pthread_testcancel()
sigwait()

On POSIX-conforming systems, the symbolic constant _POSIX_THREAD_SAFE_FUNCTIONS is always defined. Therefore, the following functions are always supported:

asctime_r()
ctime_r()
flockfile()
ftrylockfile()
funlockfile()
getc_unlocked()
getchar_unlocked()
getgrgid_r()
getgrnam_r()
getpwnam_r()
getpwuid_r()
gmtime_r()
localtime_r()
putc_unlocked()
putchar_unlocked()
rand_r()
readdir_r()
strerror_r()
strtok_r()

Threads Extensions

The following extensions to the IEEE P1003.1c draft standard are now supported in POSIX.1-2017 as part of the alignment with the Single UNIX Specification:

Extended mutex attribute types

Read-write locks and attributes (also introduced by the IEEE Std 1003.1j-2000 amendment)

Thread concurrency level

Thread stack guard size

Parallel I/O

Robust mutexes

These extensions carefully follow the threads programming model specified in POSIX.1c. As with POSIX.1c, all the new functions return zero if successful; otherwise, an error number is returned to indicate the error.

The concept of attribute objects was introduced in POSIX.1c to allow implementations to extend POSIX.1-2017 without changing the existing interfaces. Attribute objects were defined for threads, mutexes, and condition variables. Attributes objects are defined as implementation-defined opaque types to aid extensibility, and functions are defined to allow attributes to be set or retrieved. This model has been followed when adding the new type attribute of **pthread_mutexattr_t** or the new read-write lock attributes object **pthread_rwlockattr_t**.

Extended Mutex Attributes

POSIX.1c defines a mutex attributes object as an implementation-defined opaque object of type **pthread_mutexattr_t**, and specifies a number of attributes which this object must have and a number of functions which manipulate these attributes. These attributes include *detachstate*, *inheritsched*, *schedparm*, *schedpolicy*, *contentionscope*, *stackaddr*, and *stacksize*.

The System Interfaces volume of POSIX.1-2017 specifies another mutex attribute called *type*. The *type* attribute allows applications to specify the behavior of mutex locking operations in situations where POSIX.1c behavior is undefined. The OSF DCE threads implementation, based on Draft 4 of POSIX.1c, specified a similar attribute. Note that the names of the attributes have changed somewhat from the OSF DCE threads implementation.

The System Interfaces volume of POSIX.1-2017 also extends the specification of the following POSIX.1c functions which manipulate mutexes:

124455 *pthread_mutex_lock*( )
124456 *pthread_mutex_trylock*( )
124457 *pthread_mutex_unlock*( )

124458 to take account of the new mutex attribute type and to specify behavior which was
124459 declared as undefined in POSIX.1c. How a calling thread acquires or releases a mutex now
124460 depends upon the mutex *type* attribute.

124461 The *type* attribute can have the following values:

124462 PTHREAD_MUTEX_NORMAL
124463 Basic mutex with no specific error checking built in. Does not report a deadlock error.

124464 PTHREAD_MUTEX_RECURSIVE
124465 Allows any thread to recursively lock a mutex. The mutex must be unlocked an equal
124466 number of times to release the mutex.

124467 PTHREAD_MUTEX_ERRORCHECK
124468 Detects and reports simple usage errors; that is, an attempt to unlock a mutex that is
124469 not locked by the calling thread or that is not locked at all, or an attempt to relock a
124470 mutex the thread already owns.

124471 PTHREAD_MUTEX_DEFAULT
124472 The default mutex type. May be mapped to any of the above mutex types or may be
124473 an implementation-defined type.

124474 *Normal* mutexes do not detect deadlock conditions; for example, a thread will hang if it
124475 tries to relock a normal mutex that it already owns. Attempting to unlock a mutex locked
124476 by another thread, or unlocking an unlocked mutex, results in undefined behavior. Normal
124477 mutexes will usually be the fastest type of mutex available on a platform but provide the
124478 least error checking.

124479 *Recursive* mutexes are useful for converting old code where it is difficult to establish clear
124480 boundaries of synchronization. A thread can relock a recursive mutex without first
124481 unlocking it. The relocking deadlock which can occur with normal mutexes cannot occur
124482 with this type of mutex. However, multiple locks of a recursive mutex require the same
124483 number of unlocks to release the mutex before another thread can acquire the mutex.
124484 Furthermore, this type of mutex maintains the concept of an owner. Thus, a thread
124485 attempting to unlock a recursive mutex which another thread has locked returns with an
124486 error. A thread attempting to unlock a recursive mutex that is not locked returns with an
124487 error. Never use a recursive mutex with condition variables because the implicit unlock
124488 performed by *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ) will not actually release the
124489 mutex if it had been locked multiple times.

124490 *Errorcheck* mutexes provide error checking and are useful primarily as a debugging aid. A
124491 thread attempting to relock an errorcheck mutex without first unlocking it returns with an
124492 error. Again, this type of mutex maintains the concept of an owner. Thus, a thread
124493 attempting to unlock an errorcheck mutex which another thread has locked returns with
124494 an error. A thread attempting to unlock an errorcheck mutex that is not locked also returns
124495 with an error. It should be noted that errorcheck mutexes will almost always be much
124496 slower than normal mutexes due to the extra state checks performed.

124497 The default mutex type provides implementation-defined error checking. The default
124498 mutex may be mapped to one of the other defined types or may be something entirely
124499 different. This enables each vendor to provide the mutex semantics which the vendor feels
124500 will be most useful to their target users. Most vendors will probably choose to make
124501 normal mutexes the default so as to give applications the benefit of the fastest type of

mutexes available on their platform. Check your implementation's documentation.

An application developer can use any of the mutex types almost interchangeably as long as the application does not depend upon the implementation detecting (or failing to detect) any particular errors. Note that a recursive mutex can be used with condition variable waits as long as the application never recursively locks the mutex.

Two functions are provided for manipulating the *type* attribute of a mutex attributes object. This attribute is set or returned in the *type* parameter of these functions. The *pthread_mutexattr_settype*( ) function is used to set a specific type value while *pthread_mutexattr_gettype*( ) is used to return the type of the mutex. Setting the *type* attribute of a mutex attributes object affects only mutexes initialized using that mutex attributes object. Changing the *type* attribute does not affect mutexes previously initialized using that mutex attributes object.

Read-Write Locks and Attributes

The read-write locks introduced have been harmonized with those in IEEE Std 1003.1j-2000; see also Section B.2.9.6 (on page 3659).

Read-write locks (also known as reader-writer locks) allow a thread to exclusively lock some shared data while updating that data, or allow any number of threads to have simultaneous read-only access to the data.

Unlike a mutex, a read-write lock distinguishes between reading data and writing data. A mutex excludes all other threads. A read-write lock allows other threads access to the data, providing no thread is modifying the data. Thus, a read-write lock is less primitive than either a mutex-condition variable pair or a semaphore.

Application developers should consider using a read-write lock rather than a mutex to protect data that is frequently referenced but seldom modified. Most threads (readers) will be able to read the data without waiting and will only have to block when some other thread (a writer) is in the process of modifying the data. Conversely a thread that wants to change the data is forced to wait until there are no readers. This type of lock is often used to facilitate parallel access to data on multi-processor platforms or to avoid context switches on single processor platforms where multiple threads access the same data.

If a read-write lock becomes unlocked and there are multiple threads waiting to acquire the write lock, the implementation's scheduling policy determines which thread acquires the read-write lock for writing. If there are multiple threads blocked on a read-write lock for both read locks and write locks, it is unspecified whether the readers or a writer acquire the lock first. However, for performance reasons, implementations often favor writers over readers to avoid potential writer starvation.

A read-write lock object is an implementation-defined opaque object of type **pthread_rwlock_t** as defined in **<pthread.h>**. There are two different sorts of locks associated with a read-write lock: a read lock and a write lock.

The *pthread_rwlockattr_init*( ) function initializes a read-write lock attributes object with the default value for all the attributes defined in the implementation. After a read-write lock attributes object has been used to initialize one or more read-write locks, changes to the read-write lock attributes object, including destruction, do not affect previously initialized read-write locks.

Implementations must provide at least the read-write lock attribute *process-shared*. This attribute can have the following values:

PTHREAD_PROCESS_SHARED

Any thread of any process that has access to the memory where the read-write lock resides can manipulate the read-write lock.

PTHREAD_PROCESS_PRIVATE

Only threads created within the same process as the thread that initialized the read-write lock can manipulate the read-write lock. This is the default value.

The *pthread_rwlockattr_setpshared*( ) function is used to set the *process-shared* attribute of an initialized read-write lock attributes object while the function *pthread_rwlockattr_getpshared*( ) obtains the current value of the *process-shared* attribute.

A read-write lock attributes object is destroyed using the *pthread_rwlockattr_destroy*( ) function. The effect of subsequent use of the read-write lock attributes object is undefined.

A thread creates a read-write lock using the *pthread_rwlock_init*( ) function. The attributes of the read-write lock can be specified by the application developer; otherwise, the default implementation-defined read-write lock attributes are used if the pointer to the read-write lock attributes object is NULL. In cases where the default attributes are appropriate, the PTHREAD_RWLOCK_INITIALIZER macro can be used to initialize read-write locks.

A thread which wants to apply a read lock to the read-write lock can use either *pthread_rwlock_rdlock*( ) or *pthread_rwlock_tryrdlock*( ). If *pthread_rwlock_rdlock*( ) is used, the thread acquires a read lock if a writer does not hold the write lock and there are no writers blocked on the write lock. If a read lock is not acquired, the calling thread blocks until it can acquire a lock. However, if *pthread_rwlock_tryrdlock*( ) is used, the function returns immediately with the error [EBUSY] if any thread holds a write lock or there are blocked writers waiting for the write lock.

A thread which wants to apply a write lock to the read-write lock can use either of two functions: *pthread_rwlock_wrlock*( ) or *pthread_rwlock_trywrlock*( ). If *pthread_rwlock_wrlock*( ) is used, the thread acquires the write lock if no other reader or writer threads hold the read-write lock. If the write lock is not acquired, the thread blocks until it can acquire the write lock. However, if *pthread_rwlock_trywrlock*( ) is used, the function returns immediately with the error [EBUSY] if any thread is holding either a read or a write lock.

The *pthread_rwlock_unlock*( ) function is used to unlock a read-write lock object held by the calling thread. Results are undefined if the read-write lock is not held by the calling thread. If there are other read locks currently held on the read-write lock object, the read-write lock object remains in the read locked state but without the current thread as one of its owners. If this function releases the last read lock for this read-write lock object, the read-write lock object is put in the unlocked read state. If this function is called to release a write lock for this read-write lock object, the read-write lock object is put in the unlocked state.

Thread Concurrency Level

On threads implementations that multiplex user threads onto a smaller set of kernel execution entities, the system attempts to create a reasonable number of kernel execution entities for the application upon application startup.

On some implementations, these kernel entities are retained by user threads that block in the kernel. Other implementations do not *timeslice* user threads so that multiple compute-bound user threads can share a kernel thread. On such implementations, some applications may use up all the available kernel execution entities before their user-space threads are used up. The process may be left with user threads capable of doing work for the application but with no way to schedule them.

The *pthread_setconcurrency*( ) function enables an application to request more kernel

entities; that is, specify a desired concurrency level. However, this function merely provides a hint to the implementation. The implementation is free to ignore this request or to provide some other number of kernel entities. If an implementation does not multiplex user threads onto a smaller number of kernel execution entities, the *pthread_setconcurrency*() function has no effect.

The *pthread_setconcurrency*() function may also have an effect on implementations where the kernel mode and user mode schedulers cooperate to ensure that ready user threads are not prevented from running by other threads blocked in the kernel.

The *pthread_getconcurrency*() function always returns the value set by a previous call to *pthread_setconcurrency*(). However, if *pthread_setconcurrency*() was not previously called, this function returns zero to indicate that the threads implementation is maintaining the concurrency level.

Thread Stack Guard Size

DCE threads introduced the concept of a ``thread stack guard size''. Most thread implementations add a region of protected memory to a thread's stack, commonly known as a ``guard region'', as a safety measure to prevent stack pointer overflow in one thread from corrupting the contents of another thread's stack. The default size of the guard regions attribute is {PAGESIZE} bytes and is implementation-defined.

Some application developers may wish to change the stack guard size. When an application creates a large number of threads, the extra page allocated for each stack may strain system resources. In addition to the extra page of memory, the kernel's memory manager has to keep track of the different protections on adjoining pages. When this is a problem, the application developer may request a guard size of 0 bytes to conserve system resources by eliminating stack overflow protection.

Conversely an application that allocates large data structures such as arrays on the stack may wish to increase the default guard size in order to detect stack overflow. If a thread allocates two pages for a data array, a single guard page provides little protection against thread stack overflows since the thread can corrupt adjoining memory beyond the guard page.

The System Interfaces volume of POSIX.1-2017 defines a new attribute of a thread attributes object; that is, the *guardsize* attribute which allows applications to specify the size of the guard region of a thread's stack.

Two functions are provided for manipulating a thread's stack guard size. The *pthread_attr_setguardsize*() function sets the thread *guardsize* attribute, and the *pthread_attr_getguardsize*() function retrieves the current value.

An implementation may round up the requested guard size to a multiple of the configurable system variable {PAGESIZE}. In this case, *pthread_attr_getguardsize*() returns the guard size specified by the previous *pthread_attr_setguardsize*() function call and not the rounded up value.

If an application is managing its own thread stacks using the *stackaddr* attribute, the *guardsize* attribute is ignored and no stack overflow protection is provided. In this case, it is the responsibility of the application to manage stack overflow along with stack allocation.

Parallel I/O

Suppose two or more threads independently issue read requests on the same file. To read specific data from a file, a thread must first call *lseek*() to seek to the proper offset in the file, and then call *read*() to retrieve the required data. If more than one thread does this at the same time, the first thread may complete its seek call, but before it gets a chance to

issue its read call a second thread may complete its seek call, resulting in the first thread accessing incorrect data when it issues its read call. One workaround is to lock the file descriptor while seeking and reading or writing, but this reduces parallelism and adds overhead.

Instead, the System Interfaces volume of POSIX.1-2017 provides two functions to make seek/read and seek/write operations atomic. The file descriptor's current offset is unchanged, thus allowing multiple read and write operations to proceed in parallel. This improves the I/O performance of threaded applications. The *pread*( ) function is used to do an atomic read of data from a file into a buffer. Conversely, the *pwrite*( ) function does an atomic write of data from a buffer to a file.

B.2.9.1 Thread-Safety

All functions required by POSIX.1-2017 need to be thread-safe. Implementations have to provide internal synchronization when necessary in order to achieve this goal. In certain cases ‡' for example, most floating-point implementations ‡ćontext switch code may have to manage the writable shared state.

While a read from a pipe of {PIPE_BUF}*2 bytes may not generate a single atomic and thread-safe stream of bytes, it should generate ``several'' (individually atomic) thread-safe streams of bytes. Similarly, while reading from a terminal device may not generate a single atomic and thread-safe stream of bytes, it should generate some finite number of (individually atomic) and thread-safe streams of bytes. That is, concurrent calls to read for a pipe, FIFO, or terminal device are not allowed to result in corrupting the stream of bytes or other internal data. However, *read*( ), in these cases, is not required to return a single contiguous and atomic stream of bytes.

It is not required that all functions provided by POSIX.1-2017 be either async-cancel-safe or async-signal-safe.

As it turns out, some functions are inherently not thread-safe; that is, their interface specifications preclude async-signal-safety. For example, some functions (such as *asctime*( )) return a pointer to a result stored in memory space allocated by the function on a per-process basis. Such a function is not thread-safe, because its result can be overwritten by successive invocations. Other functions, while not inherently non-thread-safe, may be implemented in ways that lead to them not being thread-safe. For example, some functions (such as *rand*( )) store state information (such as a seed value, which survives multiple function invocations) in memory space allocated by the function on a per-process basis. The implementation of such a function is not thread-safe if the implementation fails to synchronize invocations of the function and thus fails to protect the state information. The problem is that when the state information is not protected, concurrent invocations can interfere with one another (for example, applications using *rand*( ) may see the same seed value).

Thread-Safety and Locking of Existing Functions

Originally, POSIX.1 was not designed to work in a multi-threaded environment, and some implementations of some existing functions will not work properly when executed concurrently. To provide routines that will work correctly in an environment with threads (``thread-safe''), two problems need to be solved:

1. Routines that maintain or return pointers to static areas internal to the routine (which may now be shared) need to be modified. The routines *ttyname*( ) and *localtime*( ) are examples.
2. Routines that access data space shared by more than one thread need to be modified. The *malloc*( ) function and the *stdio* family routines are examples.

There are a variety of constraints on these changes. The first is compatibility with the existing versions of these functions—non-thread-safe functions will continue to be in use for some time, as the original interfaces are used by existing code. Another is that the new thread-safe versions of these functions represent as small a change as possible over the familiar interfaces provided by the existing non-thread-safe versions. The new interfaces should be independent of any particular threads implementation. In particular, they should be thread-safe without depending on explicit thread-specific memory. Finally, there should be minimal performance penalty due to the changes made to the functions.

It is intended that the list of functions from POSIX.1 that cannot be made thread-safe and for which corrected versions are provided be complete.

Thread-Safety and Locking Solutions

Many of the POSIX.1 functions were thread-safe and did not change at all. However, some functions (for example, the math functions typically found in **libm**) are not thread-safe because of writable shared global state. For instance, in IEEE Std 754-1985 floating-point implementations, the computation modes and flags are global and shared.

Some functions are not thread-safe because a particular implementation is not reentrant, typically because of a non-essential use of static storage. These require only a new implementation.

Thread-safe libraries are useful in a wide range of parallel (and asynchronous) programming environments, not just within pthreads. In order to be used outside the context of pthreads, however, such libraries still have to use some synchronization method. These could either be independent of the pthread synchronization operations, or they could be a subset of the pthread interfaces. Either method results in thread-safe library implementations that can be used without the rest of pthreads.

Some functions, such as the *stdio* family interface and dynamic memory allocation functions such as *malloc*(), are inter-dependent routines that share resources (for example, buffers) across related calls. These require synchronization to work correctly, but they do not require any change to their external (user-visible) interfaces.

In some cases, such as *getc*() and *putc*(), adding synchronization is likely to create an unacceptable performance impact. In this case, slower thread-safe synchronized functions are to be provided, but the original, faster (but unsafe) functions (which may be implemented as macros) are retained under new names. Some additional special-purpose synchronization facilities are necessary for these macros to be usable in multi-threaded programs. This also requires changes in **<stdio.h>**.

The other common reason that functions are unsafe is that they return a pointer to static storage, making the functions non-thread-safe. This has to be changed, and there are three natural choices:

1. Return a pointer to thread-specific storage

   This could incur a severe performance penalty on those architectures with a costly implementation of the thread-specific data interface.

   A variation on this technique is to use *malloc*() to allocate storage for the function output and return a pointer to this storage. This technique may also have an undesirable performance impact, however, and a simplistic implementation requires that the user program explicitly free the storage object when it is no longer needed. This technique is used by some existing POSIX.1 functions. With careful implementation for infrequently used functions, there may be little or no performance or storage penalty, and the maintenance of already-standardized interfaces is a significant benefit.

2. Return the actual value computed by the function

   This technique can only be used with functions that return pointers to structures—routines that return character strings would have to wrap their output in an enclosing structure in order to return the output on the stack. There is also a negative performance impact inherent in this solution in that the output value has to be copied twice before it can be used by the calling function: once from the called routine's local buffers to the top of the stack, then from the top of the stack to the assignment target. Finally, many older compilers cannot support this technique due to a historical tendency to use internal static buffers to deliver the results of structure-valued functions.

3. Have the caller pass the address of a buffer to contain the computed value

   The only disadvantage of this approach is that extra arguments have to be provided by the calling program. It represents the most efficient solution to the problem, however, and, unlike the *malloc*() technique, it is semantically clear.

There are some routines (often groups of related routines) whose interfaces are inherently non-thread-safe because they communicate across multiple function invocations by means of static memory locations. The solution is to redesign the calls so that they are thread-safe, typically by passing the needed data as extra parameters. Unfortunately, this may require major changes to the interface as well.

A floating-point implementation using IEEE Std 754-1985 is a case in point. A less problematic example is the *rand48* family of pseudo-random number generators. The functions *getgrgid*(), *getgrnam*(), *getpwnam*(), and *getpwuid*() are another such case.

The problems with *errno* are discussed in Alternative Solutions for Per-Thread errno (on page 3574).

Some functions can be thread-safe or not, depending on their arguments. These include the *tmpnam*() and *ctermid*() functions. These functions have pointers to character strings as arguments. If the pointers are not NULL, the functions store their results in the character string; however, if the pointers are NULL, the functions store their results in an area that may be static and thus subject to overwriting by successive calls. These should only be called by multi-thread applications when their arguments are non-NULL.

Asynchronous Safety and Thread-Safety

A floating-point implementation has many modes that effect rounding and other aspects of computation. Functions in some math library implementations may change the computation modes for the duration of a function call. If such a function call is interrupted by a signal or cancellation, the floating-point state is not required to be protected.

There is a significant cost to make floating-point operations async-cancel-safe or async-signal-safe; accordingly, neither form of async safety is required.

Functions Returning Pointers to Static Storage

For those functions that are not thread-safe because they return values in fixed size statically allocated structures, alternate ``_r'' forms are provided that pass a pointer to an explicit result structure. Those that return pointers into library-allocated buffers have forms provided with explicit buffer and length parameters.

For functions that return pointers to library-allocated buffers, it makes sense to provide ``_r'' versions that allow the application control over allocation of the storage in which results are returned. This allows the state used by these functions to be managed on an application-specific basis, supporting per-thread, per-process, or other application-specific sharing relationships.

Early proposals had provided ``_r'' versions for functions that returned pointers to variable-size

buffers without providing a means for determining the required buffer size. This would have made using such functions exceedingly clumsy, potentially requiring iteratively calling them with increasingly larger guesses for the amount of storage required. Hence, *sysconf*() variables have been provided for such functions that return the maximum required buffer size.

Thus, the rule that has been followed by POSIX.1-2017 when adapting single-threaded non-thread-safe functions is as follows: all functions returning pointers to library-allocated storage should have ``_r'' versions provided, allowing the application control over the storage allocation. Those with variable-sized return values accept both a buffer address and a length parameter. The *sysconf*() variables are provided to supply the appropriate buffer sizes when required. Implementors are encouraged to apply the same rule when adapting their own existing functions to a pthreads environment.

POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0020 [631], XSH/TC2-2008/0021 [826], and XSH/TC2-2008/0022 [631] are applied.

B.2.9.2 Thread IDs

Separate applications should communicate through well-defined interfaces and should not depend on each other's implementation. For example, if a programmer decides to rewrite the *sort* utility using multiple threads, it should be easy to do this so that the interface to the *sort* utility does not change. Consider that if the user causes SIGINT to be generated while the *sort* utility is running, keeping the same interface means that the entire *sort* utility is killed, not just one of its threads. As another example, consider a realtime application that manages a reactor. Such an application may wish to allow other applications to control the priority at which it watches the control rods. One technique to accomplish this is to write the ID of the thread watching the control rods into a file and allow other programs to change the priority of that thread as they see fit. A simpler technique is to have the reactor process accept IPCs (Interprocess Communication messages) from other processes, telling it at a semantic level what priority the program should assign to watching the control rods. This allows the programmer greater flexibility in the implementation. For example, the programmer can change the implementation from having one thread per rod to having one thread watching all of the rods without changing the interface. Having threads live inside the process means that the implementation of a process is invisible to outside processes (excepting debuggers and system management tools).

Threads do not provide a protection boundary. Every thread model allows threads to share memory with other threads and encourages this sharing to be widespread. This means that one thread can wipe out memory that is needed for the correct functioning of other threads that are sharing its memory. Consequently, providing each thread with its own user and/or group IDs would not provide a protection boundary between threads sharing memory.

Some applications make the assumption that the implementation can always detect invalid uses of thread IDs of type **pthread_t**. This is an invalid assumption. Specifically, if **pthread_t** is defined as a pointer type, no access check needs to be performed before using the ID.

As with other interfaces that take pointer parameters, the outcome of passing an invalid parameter can result in an invalid memory reference or an attempt to access an undefined portion of a memory object, cause signals to be sent (SIGSEGV or SIGBUS) and possible termination of the process. This is a similar case to passing an invalid buffer pointer to *read*(). Some implementations might implement *read*() as a system call and set an [EFAULT] error condition. Other implementations might contain parts of *read*() at user level and the first attempt to access data at an invalid reference will cause a signal to be sent instead.

If an implementation detects use of a thread ID after the end of its lifetime, it is recommended that the function should fail and report an [ESRCH] error. This does not imply that

124828 implementations are required to return in this case. It is legitimate behavior to send an ``invalid
124829 memory reference'' signal (SIGSEGV or SIGBUS). It is the application's responsibility to use only
124830 valid thread IDs and to keep track of the lifetime of the underlying threads.

124831 *B.2.9.3 Thread Mutexes*

124832 There is no additional rationale provided for this section.

124833 *B.2.9.4 Thread Scheduling*

124834 Scheduling Implementation Models

124835 The following scheduling implementation models are presented in terms of threads and
124836 ``kernel entities''. This is to simplify exposition of the models, and it does not imply that
124837 an implementation actually has an identifiable ``kernel entity''.

124838 A kernel entity is not defined beyond the fact that it has scheduling attributes that are used
124839 to resolve contention with other kernel entities for execution resources. A kernel entity
124840 may be thought of as an envelope that holds a thread or a separate kernel thread. It is not a
124841 conventional process, although it shares with the process the attribute that it has a single
124842 thread of control; it does not necessarily imply an address space, open files, and so on. It is
124843 better thought of as a primitive facility upon which conventional processes and threads
124844 may be constructed.

124845 ‡ystem Thread Scheduling Model

124846 This model consists of one thread per kernel entity. The kernel entity is solely
124847 responsible for scheduling thread execution on one or more processors. This model
124848 schedules all threads against all other threads in the system using the scheduling
124849 attributes of the thread.

124850 ‡roPess Scheduling Model

124851 A generalized process scheduling model consists of two levels of scheduling. A
124852 threads library creates a pool of kernel entities, as required, and schedules threads to
124853 run on them using the scheduling attributes of the threads. Typically, the size of the
124854 pool is a function of the simultaneously runnable threads, not the total number of
124855 threads. The kernel then schedules the kernel entities onto processors according to
124856 their scheduling attributes, which are managed by the threads library. This set model
124857 potentially allows a wide range of mappings between threads and kernel entities.

124858 System and Process Scheduling Model Performance

124859 There are a number of important implications on the performance of applications using
124860 these scheduling models. The process scheduling model potentially provides lower
124861 overhead for making scheduling decisions, since there is no need to access kernel-level
124862 information or functions and the set of schedulable entities is smaller (only the threads
124863 within the process).

124864 On the other hand, since the kernel is also making scheduling decisions regarding the
124865 system resources under its control (for example, CPU(s), I/O devices, memory), decisions
124866 that do not take thread scheduling parameters into account can result in unspecified
124867 delays for realtime application threads, causing them to miss maximum response time
124868 limits.

Rate Monotonic Scheduling

Rate monotonic scheduling was considered, but rejected for standardization in the context of pthreads. A sporadic server policy is included.

Scheduling Options

In POSIX.1-2017, the basic thread scheduling functions are defined under the threads functionality, so that they are required of all threads implementations. However, there are no specific scheduling policies required by this functionality to allow for conforming thread implementations that are not targeted to realtime applications.

Specific standard scheduling policies are defined to be under the Thread Execution Scheduling option, and they are specifically designed to support realtime applications by providing predictable resource-sharing sequences. The name of this option was chosen to emphasize that this functionality is defined as appropriate for realtime applications that require simple priority-based scheduling.

It is recognized that these policies are not necessarily satisfactory for some multi-processor implementations, and work is ongoing to address a wider range of scheduling behaviors. The interfaces have been chosen to create abundant opportunity for future scheduling policies to be implemented and standardized based on this interface. In order to standardize a new scheduling policy, all that is required (from the standpoint of thread scheduling attributes) is to define a new policy name, new members of the thread attributes object, and functions to set these members when the scheduling policy is equal to the new value.

Scheduling Contention Scope

In order to accommodate the requirement for realtime response, each thread has a scheduling contention scope attribute. Threads with a system scheduling contention scope have to be scheduled with respect to all other threads in the system. These threads are usually bound to a single kernel entity that reflects their scheduling attributes and are directly scheduled by the kernel.

Threads with a process scheduling contention scope need be scheduled only with respect to the other threads in the process. These threads may be scheduled within the process onto a pool of kernel entities. The implementation is also free to bind these threads directly to kernel entities and let them be scheduled by the kernel. Process scheduling contention scope allows the implementation the most flexibility and is the default if both contention scopes are supported and none is specified.

Thus, the choice by implementors to provide one or the other (or both) of these scheduling models is driven by the need of their supported application domains for worst-case (that is, realtime) response, or average-case (non-realtime) response.

Scheduling Allocation Domain

The SCHED_FIFO and SCHED_RR scheduling policies take on different characteristics on a multi-processor. Other scheduling policies are also subject to changed behavior when executed on a multi-processor. The concept of scheduling allocation domain determines the set of processors on which the threads of an application may run. By considering the application's processor scheduling allocation domain for its threads, scheduling policies can be defined in terms of their behavior for varying processor scheduling allocation domain values. It is conceivable that not all scheduling allocation domain sizes make sense for all scheduling policies on all implementations. The concept of scheduling allocation domain, however, is a useful tool for the description of multi-processor scheduling policies.

The ``process control'' approach to scheduling obtains significant performance advantages from dynamic scheduling allocation domain sizes when it is applicable.

Non-Uniform Memory Access (NUMA) multi-processors may use a system scheduling structure that involves reassignment of threads among scheduling allocation domains. In NUMA machines, a natural model of scheduling is to match scheduling allocation domains to clusters of processors. Load balancing in such an environment requires changing the scheduling allocation domain to which a thread is assigned.

Scheduling Documentation

Implementation-provided scheduling policies need to be completely documented in order to be useful. This documentation includes a description of the attributes required for the policy, the scheduling interaction of threads running under this policy and all other supported policies, and the effects of all possible values for processor scheduling allocation domain. Note that for the implementor wishing to be minimally-compliant, it is (minimally) acceptable to define the behavior as undefined.

Scheduling Contention Scope Attribute

The scheduling contention scope defines how threads compete for resources. Within POSIX.1-2017, scheduling contention scope is used to describe only how threads are scheduled in relation to one another in the system. That is, either they are scheduled against all other threads in the system (``system scope'') or only against those threads in the process (``process scope''). In fact, scheduling contention scope may apply to additional resources, including virtual timers and profiling, which are not currently considered by POSIX.1-2017.

Mixed Scopes

If only one scheduling contention scope is supported, the scheduling decision is straightforward. To perform the processor scheduling decision in a mixed scope environment, it is necessary to map the scheduling attributes of the thread with process-wide contention scope to the same attribute space as the thread with system-wide contention scope.

Since a conforming implementation has to support one and may support both scopes, it is useful to discuss the effects of such choices with respect to example applications. If an implementation supports both scopes, mixing scopes provides a means of better managing system-level (that is, kernel-level) and library-level resources. In general, threads with system scope will require the resources of a separate kernel entity in order to guarantee the scheduling semantics. On the other hand, threads with process scope can share the resources of a kernel entity while maintaining the scheduling semantics.

The application is free to create threads with dedicated kernel resources, and other threads that multiplex kernel resources. Consider the example of a window server. The server allocates two threads per widget: one thread manages the widget user interface (including drawing), while the other thread takes any required application action. This allows the widget to be ``active'' while the application is computing. A screen image may be built from thousands of widgets. If each of these threads had been created with system scope, then most of the kernel-level resources might be wasted, since only a few widgets are active at any one time. In addition, mixed scope is particularly useful in a window server where one thread with high priority and system scope handles the mouse so that it tracks well. As another example, consider a database server. For each of the hundreds or thousands of clients supported by a large server, an equivalent number of threads will have to be created. If each of these threads were system scope, the consequences would be the same as for the window server example above. However, the server could be constructed so that actual retrieval of data is done by several dedicated threads. Dedicated threads that do work for all clients frequently justify the added expense of system

scope. If it were not permissible to mix system and process threads in the same process, this type of solution would not be possible.

Dynamic Thread Scheduling Parameters Access

In many time-constrained applications, there is no need to change the scheduling attributes dynamically during thread or process execution, since the general use of these attributes is to reflect directly the time constraints of the application. Since these time constraints are generally imposed to meet higher-level system requirements, such as accuracy or availability, they frequently should remain unchanged during application execution.

However, there are important situations in which the scheduling attributes should be changed. Generally, this will occur when external environmental conditions exist in which the time constraints change. Consider, for example, a space vehicle major mode change, such as the change from ascent to descent mode, or the change from the space environment to the atmospheric environment. In such cases, the frequency with which many of the sensors or actuators need to be read or written will change, which will necessitate a priority change. In other cases, even the existence of a time constraint might be temporary, necessitating not just a priority change, but also a policy change for ongoing threads or processes. For this reason, it is critical that the interface should provide functions to change the scheduling parameters dynamically, but, as with many of the other realtime functions, it is important that applications use them properly to avoid the possibility of unnecessarily degrading performance.

In providing functions for dynamically changing the scheduling behavior of threads, there were two options: provide functions to get and set the individual scheduling parameters of threads, or provide a single interface to get and set all the scheduling parameters for a given thread simultaneously. Both approaches have merit. Access functions for individual parameters allow simpler control of thread scheduling for simple thread scheduling parameters. However, a single function for setting all the parameters for a given scheduling policy is required when first setting that scheduling policy. Since the single all-encompassing functions are required, it was decided to leave the interface as minimal as possible. Note that simpler functions (such as *pthread_setprio*( ) for threads running under the priority-based schedulers) can be easily defined in terms of the all-encompassing functions.

If the *pthread_setschedparam*( ) function executes successfully, it will have set all of the scheduling parameter values indicated in *param*; otherwise, none of the scheduling parameters will have been modified. This is necessary to ensure that the scheduling of this and all other threads continues to be consistent in the presence of an erroneous scheduling parameter.

The [EPERM] error value is included in the list of possible *pthread_setschedparam*( ) error returns as a reflection of the fact that the ability to change scheduling parameters increases risks to the implementation and application performance if the scheduling parameters are changed improperly. For this reason, and based on some existing practice, it was felt that some implementations would probably choose to define specific permissions for changing either a thread's own or another thread's scheduling parameters. POSIX.1-2017 does not include portable methods for setting or retrieving permissions, so any such use of permissions is completely unspecified.

125003 **Mutex Initialization Scheduling Attributes**

125004 In a priority-driven environment, a direct use of traditional primitives like mutexes and
125005 condition variables can lead to unbounded priority inversion, where a higher priority thread can
125006 be blocked by a lower priority thread, or set of threads, for an unbounded duration of time. As a
125007 result, it becomes impossible to guarantee thread deadlines. Priority inversion can be bounded
125008 and minimized by the use of priority inheritance protocols. This allows thread deadlines to be
125009 guaranteed even in the presence of synchronization requirements.

125010 Two useful but simple members of the family of priority inheritance protocols are the basic
125011 priority inheritance protocol and the priority ceiling protocol emulation. Under the Basic
125012 Priority Inheritance protocol (governed by the Non-Robust Mutex Priority Inheritance option), a
125013 thread that is blocking higher priority threads executes at the priority of the highest priority
125014 thread that it blocks. This simple mechanism allows priority inversion to be bounded by the
125015 duration of critical sections and makes timing analysis possible.

125016 Under the Priority Ceiling Protocol Emulation protocol (governed by the Thread Priority
125017 Protection option), each mutex has a priority ceiling, usually defined as the priority of the
125018 highest priority thread that can lock the mutex. When a thread is executing inside critical
125019 sections, its priority is unconditionally increased to the highest of the priority ceilings of all the
125020 mutexes owned by the thread. This protocol has two very desirable properties in uni-processor
125021 systems. First, a thread can be blocked by a lower priority thread for at most the duration of one
125022 single critical section. Furthermore, when the protocol is correctly used in a single processor, and
125023 if threads do not become blocked while owning mutexes, mutual deadlocks are prevented.

125024 The priority ceiling emulation can be extended to multiple processor environments, in which
125025 case the values of the priority ceilings will be assigned depending on the kind of mutex that is
125026 being used: local to only one processor, or global, shared by several processors. Local priority
125027 ceilings will be assigned the usual way, equal to the priority of the highest priority thread that
125028 may lock that mutex. Global priority ceilings will usually be assigned a priority level higher
125029 than all the priorities assigned to any of the threads that reside in the involved processors to
125030 avoid the effect called remote blocking.

125031 **Change the Priority Ceiling of a Mutex**

125032 In order for the priority protect protocol to exhibit its desired properties of bounding priority
125033 inversion and avoidance of deadlock, it is critical that the ceiling priority of a mutex be the same
125034 as the priority of the highest thread that can ever hold it, or higher. Thus, if the priorities of the
125035 threads using such mutexes never change dynamically, there is no need ever to change the
125036 priority ceiling of a mutex.

125037 However, if a major system mode change results in an altered response time requirement for one
125038 or more application threads, their priority has to change to reflect it. It will occasionally be the
125039 case that the priority ceilings of mutexes held also need to change. While changing priority
125040 ceilings should generally be avoided, it is important that POSIX.1-2017 provide these interfaces
125041 for those cases in which it is necessary.

125042 *B.2.9.5 Thread Cancellation*

125043 Many existing threads packages have facilities for canceling an operation or canceling a thread.
125044 These facilities are used for implementing user requests (such as the CANCEL button in a
125045 window-based application), for implementing OR parallelism (for example, telling the other
125046 threads to stop working once one thread has found a forced mate in a parallel chess program), or
125047 for implementing the ABORT mechanism in Ada.

125048 POSIX programs traditionally have used the signal mechanism combined with either *longjmp*( )

or polling to cancel operations. Many POSIX programmers have trouble using these facilities to solve their problems efficiently in a single-threaded process. With the introduction of threads, these solutions become even more difficult to use.

The main issues with implementing a cancellation facility are specifying the operation to be canceled, cleanly releasing any resources allocated to that operation, controlling when the target notices that it has been canceled, and defining the interaction between asynchronous signals and cancellation.

Specifying the Operation to Cancel

Consider a thread that calls through five distinct levels of program abstraction and then, inside the lowest-level abstraction, calls a function that suspends the thread. (An abstraction boundary is a layer at which the client of the abstraction sees only the service being provided and can remain ignorant of the implementation. Abstractions are often layered, each level of abstraction being a client of the lower-level abstraction and implementing a higher-level abstraction.) Depending on the semantics of each abstraction, one could imagine wanting to cancel only the call that causes suspension, only the bottom two levels, or the operation being done by the entire thread. Canceling operations at a finer grain than the entire thread is difficult because threads are active and they may be run in parallel on a multi-processor. By the time one thread can make a request to cancel an operation, the thread performing the operation may have completed that operation and gone on to start another operation whose cancellation is not desired. Thread IDs are not reused until the thread has exited, and either it was created with the *Attr detachstate* attribute set to PTHREAD_CREATE_DETACHED or the *pthread_join*( ) or *pthread_detach*( ) function has been called for that thread. Consequently, a thread cancellation will never be misdirected when the thread terminates. For these reasons, the canceling of operations is done at the granularity of the thread. Threads are designed to be inexpensive enough so that a separate thread may be created to perform each separately cancelable operation; for example, each possibly long running user request.

For cancellation to be used in existing code, cancellation scopes and handlers will have to be established for code that needs to release resources upon cancellation, so that it follows the programming discipline described in the text.

A Special Signal Versus a Special Interface

Two different mechanisms were considered for providing the cancellation interfaces. The first was to provide an interface to direct signals at a thread and then to define a special signal that had the required semantics. The other alternative was to use a special interface that delivered the correct semantics to the target thread.

The solution using signals produced a number of problems. It required the implementation to provide cancellation in terms of signals whereas a perfectly valid (and possibly more efficient) implementation could have both layered on a low-level set of primitives. There were so many exceptions to the special signal (it cannot be used with *kill*( ), no POSIX.1 interfaces can be used with it) that it was clearly not a valid signal. Its semantics on delivery were also completely different from any existing POSIX.1 signal. As such, a special interface that did not mandate the implementation and did not confuse the semantics of signals and cancellation was felt to be the better solution.

125091 **Races Between Cancellation and Resuming Execution**

125092 Due to the nature of cancellation, there is generally no synchronization between the thread
125093 requesting the cancellation of a blocked thread and events that may cause that thread to resume
125094 execution. For this reason, and because excess serialization hurts performance, when both an
125095 event that a thread is waiting for has occurred and a cancellation request has been made and
125096 cancellation is enabled, POSIX.1-2017 explicitly allows the implementation to choose between
125097 returning from the blocking call or acting on the cancellation request.

125098 **Interaction of Cancellation with Asynchronous Signals**

125099 A typical use of cancellation is to acquire a lock on some resource and to establish a cancellation
125100 cleanup handler for releasing the resource when and if the thread is canceled.

125101 A correct and complete implementation of cancellation in the presence of asynchronous signals
125102 requires considerable care. An implementation has to push a cancellation cleanup handler on the
125103 cancellation cleanup stack while maintaining the integrity of the stack data structure. If an
125104 asynchronously-generated signal is posted to the thread during a stack operation, the signal
125105 handler cannot manipulate the cancellation cleanup stack. As a consequence, asynchronous
125106 signal handlers may not cancel threads or otherwise manipulate the cancellation state of a
125107 thread. Threads may, of course, be canceled by another thread that used a *sigwait*() function to
125108 wait synchronously for an asynchronous signal.

125109 In order for cancellation to function correctly, it is required that asynchronous signal handlers
125110 not change the cancellation state. This requires that some elements of existing practice, such as
125111 using *longjmp*() to exit from an asynchronous signal handler implicitly, be prohibited in cases
125112 where the integrity of the cancellation state of the interrupt thread cannot be ensured.

125113 **Thread Cancellation Overview**

125114 Cancelability States

125115 The three possible cancelability states (disabled, deferred, and asynchronous) are encoded
125116 into two separate bits ((disable, enable) and (deferred, asynchronous)) to allow them to be
125117 changed and restored independently. For instance, short code sequences that will not block
125118 sometimes disable cancelability on entry and restore the previous state upon exit.
125119 Likewise, long or unbounded code sequences containing no convenient explicit
125120 cancellation points will sometimes set the cancelability type to asynchronous on entry and
125121 restore the previous value upon exit.

125122 Cancellation Points

125123 Cancellation points are points inside of certain functions where a thread has to act on any
125124 pending cancellation request when cancelability is enabled. For functions in the ``shall
125125 occur'' list, a cancellation check must be performed on every call regardless of whether,
125126 absent the cancellation, the call would have blocked. For functions in the ``may occur'' list,
125127 a cancellation check may be performed on some calls but not others; i.e., whether or not a
125128 cancellation point occurs when one of these functions is being executed can depend on
125129 current conditions.

125130 The idea was considered of allowing implementations to define whether blocking calls
125131 such as *read*() should be cancellation points. It was decided that it would adversely affect
125132 the design of conforming applications if blocking calls were not cancellation points
125133 because threads could be left blocked in an uncancelable state.

125134 There are several important blocking routines that are specifically not made cancellation
125135 points:

‡*pthread_mutex_lock*( )

If *pthread_mutex_lock*( ) were a cancellation point, every routine that called it would also become a cancellation point (that is, any routine that touched shared state would automatically become a cancellation point). For example, *malloc*( ), *free*( ), and *rand*( ) would become cancellation points under this scheme. Having too many cancellation points makes programming very difficult, leading to either much disabling and restoring of cancelability or much difficulty in trying to arrange for reliable cleanup at every possible place.

Since *pthread_mutex_lock*( ) is not a cancellation point, threads could result in being blocked uninterruptibly for long periods of time if mutexes were used as a general synchronization mechanism. As this is normally not acceptable, mutexes should only be used to protect resources that are held for small fixed lengths of time where not being able to be canceled will not be a problem. Resources that need to be held exclusively for long periods of time should be protected with condition variables.

‡*pthread_barrier_wait*( )

Canceling a barrier wait will render a barrier unusable. Similar to a barrier timeout (which the standard developers rejected), there is no way to guarantee the consistency of a barrier's internal data structures if a barrier wait is canceled.

‡*pthread_spin_lock*( )

As with mutexes, spin locks should only be used to protect resources that are held for small fixed lengths of time where not being cancelable will not be a problem.

Every library routine should specify whether or not it includes any cancellation points. Typically, only those routines that may block or compute indefinitely need to include cancellation points.

Correctly coded routines only reach cancellation points after having set up a cancellation cleanup handler to restore invariants if the thread is canceled at that point. Being cancelable only at specified cancellation points allows programmers to keep track of actions needed in a cancellation cleanup handler more easily. A thread should only be made asynchronously cancelable when it is not in the process of acquiring or releasing resources or otherwise in a state from which it would be difficult or impossible to recover.

Thread Cancellation Cleanup Handlers

The cancellation cleanup handlers provide a portable mechanism, easy to implement, for releasing resources and restoring invariants. They are easier to use than signal handlers because they provide a stack of cancellation cleanup handlers rather than a single handler, and because they have an argument that can be used to pass context information to the handler.

The alternative to providing these simple cancellation cleanup handlers (whose only use is for cleaning up when a thread is canceled) is to define a general exception package that could be used for handling and cleaning up after hardware traps and software-detected errors. This was too far removed from the charter of providing threads to handle asynchrony. However, it is an explicit goal of POSIX.1-2017 to be compatible with existing exception facilities and languages having exceptions.

The interaction of this facility and other procedure-based or language-level exception facilities is unspecified in this version of POSIX.1-2017. However, it is intended that it be possible for an implementation to define the relationship between these cancellation cleanup handlers and Ada, C++, or other language-level exception handling facilities.

125182 It was suggested that the cancellation cleanup handlers should also be called when the
125183 process exits or calls the *exec* function. This was rejected partly due to the performance
125184 problem caused by having to call the cancellation cleanup handlers of every thread before
125185 the operation could continue. The other reason was that the only state expected to be
125186 cleaned up by the cancellation cleanup handlers would be the intraprocess state. Any
125187 handlers that are to clean up the interprocess state would be registered with *atexit*( ). There
125188 is the orthogonal problem that the *exec* functions do not honor the *atexit*( ) handlers, but
125189 resolving this is beyond the scope of POSIX.1-2017.

125190 Async-Cancel Safety

125191 A function is said to be async-cancel-safe if it is written in such a way that entering the
125192 function with asynchronous cancelability enabled will not cause any invariants to be
125193 violated, even if a cancellation request is delivered at any arbitrary instruction. Functions
125194 that are async-cancel-safe are often written in such a way that they need to acquire no
125195 resources for their operation and the visible variables that they may write are strictly
125196 limited.

125197 Any routine that gets a resource as a side-effect cannot be made async-cancel-safe (for
125198 example, *malloc*( )). If such a routine were called with asynchronous cancelability enabled,
125199 it might acquire the resource successfully, but as it was returning to the client, it could act
125200 on a cancellation request. In such a case, the application would have no way of knowing
125201 whether the resource was acquired or not.

125202 Indeed, because many interesting routines cannot be made async-cancel-safe, most library
125203 routines in general are not async-cancel-safe. Every library routine should specify whether
125204 or not it is async-cancel safe so that programmers know which routines can be called from
125205 code that is asynchronously cancelable.

125206 IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/8 is applied, adding the *pselect*( ) function
125207 to the list of functions with cancellation points.

125208 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/5 is applied, adding the *fdatasync*( )
125209 function into the table of functions that shall have cancellation points.

125210 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/6 is applied, adding the numerous
125211 functions into the table of functions that may have cancellation points.

125212 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/7 is applied, clarifying the requirements
125213 in Thread Cancellation Cleanup Handlers.

125214 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0023 [627], XSH/TC2-2008/0024
125215 [627,632], XSH/TC2-2008/0025 [627], XSH/TC2-2008/0026 [632], and XSH/TC2-2008/0027
125216 [622] are applied.

125217 *B.2.9.6 Thread Read-Write Locks*

125218 **Background**

125219 Read-write locks are often used to allow parallel access to data on multi-processors, to avoid
125220 context switches on uni-processors when multiple threads access the same data, and to protect
125221 data structures that are frequently accessed (that is, read) but rarely updated (that is, written).
125222 The in-core representation of a file system directory is a good example of such a data structure.
125223 One would like to achieve as much concurrency as possible when searching directories, but limit
125224 concurrent access when adding or deleting files.

125225 Although read-write locks can be implemented with mutexes and condition variables, such
125226 implementations are significantly less efficient than is possible. Therefore, this synchronization

125227 primitive is included in POSIX.1-2017 for the purpose of allowing more efficient
125228 implementations in multi-processor systems.

125229 **Queuing of Waiting Threads**

125230 The *pthread_rwlock_unlock*() function description states that one writer or one or more readers
125231 must acquire the lock if it is no longer held by any thread as a result of the call. However, the
125232 function does not specify which thread(s) acquire the lock, unless the Thread Execution
125233 Scheduling option is supported.

125234 The standard developers considered the issue of scheduling with respect to the queuing of
125235 threads blocked on a read-write lock. The question turned out to be whether POSIX.1-2017
125236 should require priority scheduling of read-write locks for threads whose execution scheduling
125237 policy is priority-based (for example, SCHED_FIFO or SCHED_RR). There are tradeoffs
125238 between priority scheduling, the amount of concurrency achievable among readers, and the
125239 prevention of writer and/or reader starvation.

125240 For example, suppose one or more readers hold a read-write lock and the following threads
125241 request the lock in the listed order:

```
125242 pthread_rwlock_wrlock() - Low priority thread writer_a
125243 pthread_rwlock_rdlock() - High priority thread reader_a
125244 pthread_rwlock_rdlock() - High priority thread reader_b
125245 pthread_rwlock_rdlock() - High priority thread reader_c
```

125246 When the lock becomes available, should *writer_a* block the high priority readers? Or, suppose a
125247 read-write lock becomes available and the following are queued:

```
125248 pthread_rwlock_rdlock() - Low priority thread reader_a
125249 pthread_rwlock_rdlock() - Low priority thread reader_b
125250 pthread_rwlock_rdlock() - Low priority thread reader_c
125251 pthread_rwlock_wrlock() - Medium priority thread writer_a
125252 pthread_rwlock_rdlock() - High priority thread reader_d
```

125253 If priority scheduling is applied then *reader_d* would acquire the lock and *writer_a* would block
125254 the remaining readers. But should the remaining readers also acquire the lock to increase
125255 concurrency? The solution adopted takes into account that when the Thread Execution
125256 Scheduling option is supported, high priority threads may in fact starve low priority threads
125257 (the application developer is responsible in this case for designing the system in such a way that
125258 this starvation is avoided). Therefore, POSIX.1-2017 specifies that high priority readers take
125259 precedence over lower priority writers. However, to prevent writer starvation from threads of
125260 the same or lower priority, writers take precedence over readers of the same or lower priority.

125261 Priority inheritance mechanisms are non-trivial in the context of read-write locks. When a high
125262 priority writer is forced to wait for multiple readers, for example, it is not clear which subset of
125263 the readers should inherit the writer's priority. Furthermore, the internal data structures that
125264 record the inheritance must be accessible to all readers, and this implies some sort of
125265 serialization that could negate any gain in parallelism achieved through the use of multiple
125266 readers in the first place. Finally, existing practice does not support the use of priority
125267 inheritance for read-write locks. Therefore, no specification of priority inheritance or priority
125268 ceiling is attempted. If reliable priority-scheduled synchronization is absolutely required, it can
125269 always be obtained through the use of mutexes.

125270 **Comparison to fcntl() Locks**

125271 The read-write locks and the *fcntl*() locks in POSIX.1-2017 share a common goal: increasing
125272 concurrency among readers, thus increasing throughput and decreasing delay.

125273 However, the read-write locks have two features not present in the *fcntl*() locks. First, under
125274 priority scheduling, read-write locks are granted in priority order. Second, also under priority
125275 scheduling, writer starvation is prevented by giving writers preference over readers of equal or
125276 lower priority.

125277 Also, read-write locks can be used in systems lacking a file system, such as those conforming to
125278 the minimal realtime system profile of IEEE Std 1003.13-1998.

125279 **History of Resolution Issues**

125280 Based upon some balloting objections, early drafts specified the behavior of threads waiting on a
125281 read-write lock during the execution of a signal handler, as if the thread had not called the lock
125282 operation. However, this specified behavior would require implementations to establish
125283 internal signal handlers even though this situation would be rare, or never happen for many
125284 programs. This would introduce an unacceptable performance hit in comparison to the little
125285 additional functionality gained. Therefore, the behavior of read-write locks and signals was
125286 reverted back to its previous mutex-like specification.

125287 *B.2.9.7 Thread Interactions with Regular File Operations*

125288 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0028 [498] is applied.

125289 *B.2.9.8 Use of Application-Managed Thread Stacks*

125290 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/8 is applied, adding this new section. It
125291 was added to make it clear that the current standard does not allow an application to determine
125292 when a stack can be reclaimed. This may be addressed in a future version.

125293 *B.2.9.9 Synchronization Object Copies and Alternative Mappings*

125294 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0029 [972] is applied.

125295 ## B.2.10 Sockets

125296 The base document for the sockets interfaces in POSIX.1-2017 is the XNS, Issue 5.2 specification.
125297 This was primarily chosen as it aligns with IPv6. Additional material has been added from
125298 IEEE Std 1003.1g-2000, notably socket concepts, raw sockets, the *pselect*() function, the
125299 *sockatmark*() function, and the **<sys/select.h>** header.

125300 *B.2.10.1 Address Families*

125301 There is no additional rationale provided for this section.

125302 *B.2.10.2 Addressing*

125303 There is no additional rationale provided for this section.

125304 *B.2.10.3 Protocols*

125305 There is no additional rationale provided for this section.

125306 *B.2.10.4 Routing*

125307 There is no additional rationale provided for this section.

125308 *B.2.10.5 Interfaces*

125309 There is no additional rationale provided for this section.

125310 *B.2.10.6 Socket Types*

125311 The type **socklen_t** was invented to cover the range of implementations seen in the field. The
125312 intent of **socklen_t** is to be the type for all lengths that are naturally bounded in size; that is, that
125313 they are the length of a buffer which cannot sensibly become of massive size: network addresses,
125314 host names, string representations of these, ancillary data, control messages, and socket options
125315 are examples. Truly boundless sizes are represented by **size_t** as in *read*( ), *write*( ), and so on.

125316 All **socklen_t** types were originally (in BSD UNIX) of type **int**. During the development of
125317 POSIX.1-2017, it was decided to change all buffer lengths to **size_t**, which appears at face value
125318 to make sense. When dual mode 32/64-bit systems came along, this choice unnecessarily
125319 complicated system interfaces because **size_t** (with **long**) was a different size under ILP32 and
125320 LP64 models. Reverting to **int** would have happened except that some implementations had
125321 already shipped 64-bit-only interfaces. The compromise was a type which could be defined to be
125322 any size by the implementation: **socklen_t**.

125323 *B.2.10.7 Socket I/O Mode*

125324 There is no additional rationale provided for this section.

125325 *B.2.10.8 Socket Owner*

125326 There is no additional rationale provided for this section.

125327 *B.2.10.9 Socket Queue Limits*

125328 There is no additional rationale provided for this section.

125329 *B.2.10.10 Pending Error*

125330 There is no additional rationale provided for this section.

125331 *B.2.10.11 Socket Receive Queue*

125332 There is no additional rationale provided for this section.

125333 *B.2.10.12 Socket Out-of-Band Data State*

125334 There is no additional rationale provided for this section.

125335 *B.2.10.13 Connection Indication Queue*

125336 There is no additional rationale provided for this section.

125337 *B.2.10.14 Signals*

125338 There is no additional rationale provided for this section.

125339 *B.2.10.15 Asynchronous Errors*

125340 There is no additional rationale provided for this section.

125341 *B.2.10.16 Use of Options*

125342 There is no additional rationale provided for this section.

125343 *B.2.10.17 Use of Sockets for Local UNIX Connections*

125344 There is no additional rationale provided for this section.

125345 *B.2.10.18 Use of Sockets over Internet Protocols*

125346 A raw socket allows privileged users direct access to a protocol; for example, raw access to the
125347 IP and ICMP protocols is possible through raw sockets. Raw sockets are intended for
125348 knowledgeable applications that wish to take advantage of some protocol feature not directly
125349 accessible through the other sockets interfaces.

125350 *B.2.10.19 Use of Sockets over Internet Protocols Based on IPv4*

125351 There is no additional rationale provided for this section.

125352 *B.2.10.20 Use of Sockets over Internet Protocols Based on IPv6*

125353 The Open Group Base Resolution bwg2001-012 is applied, clarifying that IPv6 implementations
125354 are required to support use of AF_INET6 sockets over IPv4.

B.2.11 Tracing

The organization of the tracing rationale differs from the traditional rationale in that this tracing rationale text is written against the trace interface as a whole, rather than against the individual components of the trace interface or the normative section in which those components are defined. Therefore the sections below do not parallel the sections of normative text in POSIX.1-2017.

B.2.11.1 Objectives

The intended uses of tracing are application-system debugging during system development, as a ``flight recorder'' for maintenance of fielded systems, and as a performance measurement tool. In all of these intended uses, the vendor-supplied computer system and its software are, for this discussion, assumed error-free; the intent being to debug the user-written and/or third-party application code, and their interactions. Clearly, problems with the vendor-supplied system and its software will be uncovered from time to time, but this is a byproduct of the primary activity, debugging user code.

Another need for defining a trace interface in POSIX stems from the objective to provide an efficient portable way to perform benchmarks. Existing practice shows that such interfaces are commonly used in a variety of systems but with little commonality. As part of the benchmarking needs, two aspects within the trace interface must be considered.

The first, and perhaps more important one, is the qualitative aspect.

The second is the quantitative aspect.

Qualitative Aspect

To better understand this aspect, let us consider an example. Suppose that you want to organize a number of actions to be performed during the day. Some of these actions are known at the beginning of the day. Some others, which may be more or less important, will be triggered by reading your mail. During the day you will make some phone calls and synchronously receive some more information. Finally you will receive asynchronous phone calls that also will trigger actions. If you, or somebody else, examines your day at work, you, or he, can discover that you have not efficiently organized your work. For instance, relative to the phone calls you made, would it be preferable to make some of these early in the morning? Or to delay some others until the end of the day? Relative to the phone calls you have received, you might find that somebody you called in the morning has called you 10 times while you were performing some important work. To examine, afterwards, your day at work, you record in sequence all the trace events relative to your work. This should give you a chance of organizing your next day at work.

This is the qualitative aspect of the trace interface. The user of a system needs to keep a trace of particular points the application passes through, so that he can eventually make some changes in the application and/or system configuration, to give the application a chance of running more efficiently.

Quantitative Aspect

This aspect concerns primarily realtime applications, where missed deadlines can be undesirable. Although there are, in POSIX.1-2017, some interfaces useful for such applications (timeouts, execution time monitoring, and so on), there are no APIs to aid in the tuning of a realtime application's behavior (**timespec** in timeouts, length of message queues, duration of driver interrupt service routine, and so on). The tuning of an application needs a means of recording timestamped important trace events during execution in order to analyze offline, and eventually, to tune some realtime features

125401 (redesign the system with less functionalities, readjust timeouts, redesign driver interrupts,
125402 and so on).

125403 **Detailed Objectives**

125404 Objectives were defined to build the trace interface and are kept for historical interest. Although
125405 some objectives are not fully respected in this trace interface, the concept of the POSIX trace
125406 interface assumes the following points:

125407 1. It must be possible to trace both system and user trace events concurrently.

125408 2. It must be possible to trace per-process trace events and also to trace system trace events
125409 which are unrelated to any particular process. A per-process trace event is either user-
125410 initiated or system-initiated.

125411 3. It must be possible to control tracing on a per-process basis from either inside or outside
125412 the process.

125413 4. It must be possible to control tracing on a per-thread basis from inside the enclosing
125414 process.

125415 5. Trace points must be controllable by trace event type ID from inside and outside of the
125416 process. Multiple trace points can have the same trace event type ID, and will be
125417 controlled jointly.

125418 6. Recording of trace events is dependent on both trace event type ID and the
125419 process/thread. Both must be enabled in order to record trace events. System trace events
125420 may or may not be handled differently.

125421 7. The API must not mandate the ability to control tracing for more than one process at the
125422 same time.

125423 8. There is no objective for trace control on anything bigger than a process; for example,
125424 group or session.

125425 9. Trace propagation and control:

125426 a. Trace propagation across *fork*() is optional; the default is to not trace a child
125427 process.

125428 b. Trace control must span *pthread_create*() operations; that is, if a process is being
125429 traced, any thread will be traced as well if this thread allows tracing. The default is
125430 to allow tracing.

125431 10. Trace control must not span *exec* or *posix_spawn*() operations.

125432 11. A triggering API is not required. The triggering API is the ability to command or stop
125433 tracing based on the occurrence of a specific trace event other than a
125434 POSIX_TRACE_START trace event or a POSIX_TRACE_STOP trace event.

125435 12. Trace log entries must have timestamps of implementation-defined resolution.
125436 Implementations are exhorted to support at least microsecond resolution. When a trace
125437 log entry is retrieved, it must have timestamp, PC address, PID, and TID of the entity that
125438 generated the trace event.

125439 13. Independently developed code should be able to use trace facilities without coordination
125440 and without conflict.

125441 14. Even if the trace points in the trace calls are not unique, the trace log entries (after any
125442 processing) must be uniquely identified as to trace point.

15. There must be a standard API to read the trace stream.
16. The format of the trace stream and the trace log is opaque and unspecified.
17. It must be possible to read a completed trace, if recorded on some suitable non-volatile storage, even subsequent to a power cycle or subsequent cold boot of the system.
18. Support of analysis of a trace log while it is being formed is implementation-defined.
19. The API must allow the application to write trace stream identification information into the trace stream and to be able to retrieve it, without it being overwritten by trace entries, even if the trace stream is full.
20. It must be possible to specify the destination of trace data produced by trace events.
21. It must be possible to have different trace streams, and for the tracing enabled by one trace stream to be completely independent of the tracing of another trace stream.
22. It must be possible to trace events from threads in different CPUs.
23. The API must support one or more trace streams per-system, and one or more trace streams per-process, up to an implementation-defined set of per-system and per-process maximums.
24. It must be possible to determine the order in which the trace events happened, without necessarily depending on the clock, up to an implementation-defined time resolution.
25. For performance reasons, the trace event point call(s) must be implementable as a macro (see the ISO POSIX-1: 1996 standard, 1.3.4, Statement 2).
26. POSIX.1-2017 must not define the trace points which a conforming system must implement, except for trace points used in the control of tracing.
27. The APIs must be thread-safe, and trace points should be lock-free (that is, not require a lock to gain exclusive access to some resource).
28. The user-provided information associated with a trace event is variable-sized, up to some maximum size.
29. Bounds on record and trace stream sizes:
    a. The API must permit the application to declare the upper bounds on the length of an application data record. The system must return the limit it used. The limit used may be smaller than requested.
    b. The API must permit the application to declare the upper bounds on the size of trace streams. The system must return the limit it used. The limit used may be different, either larger or smaller, than requested.
30. The API must be able to pass any fundamental data type, and a structured data type composed only of fundamental types. The API must be able to pass data by reference, given only as an address and a length. Fundamental types are the POSIX.1 types (see the **<sys/types.h>** header) plus those defined in the ISO C standard.
31. The API must apply the POSIX notions of ownership and permission to recorded trace data, corresponding to the sources of that data.

125481 **Comments on Objectives**

125482 **Note:** In the following comments, numbers in square brackets refer to the above objectives.

125483 It is necessary to be able to obtain a trace stream for a complete activity. Thus there is a
125484 requirement to be able to trace both application and system trace events. A per-process trace
125485 event is either user-initiated, like the *write*( ) function, or system-initiated, like a timer expiration.
125486 There is also a need to be able to trace the activity of an entire process even when it has threads
125487 in multiple CPUs. To avoid excess trace activity, it is necessary to be able to control tracing on a
125488 trace event type basis.
125489 [Objectives 1,2,5,22]

125490 There is a need to be able to control tracing on a per-process basis, both from inside and outside
125491 the process; that is, a process can start a trace activity on itself or any other process. There is also
125492 the perceived need to allow the definition of a maximum number of trace streams per system.
125493 [Objectives 3,23]

125494 From within a process, it is necessary to be able to control tracing on a per-thread basis. This
125495 provides an additional filtering capability to keep the amount of traced data to a minimum. It
125496 also allows for less ambiguity as to the origin of trace events. It is recognized that thread-level
125497 control is only valid from within the process itself. It is also desirable to know the maximum
125498 number of trace streams per process that can be started. The API should not require thread
125499 synchronization or mandate priority inversions that would cause the thread to block. However,
125500 the API must be thread-safe.
125501 [Objectives 4,23,24,27]

125502 There was no perceived objective to control tracing on anything larger than a process; for
125503 example, a group or session. Also, the ability to start or stop a trace activity on multiple
125504 processes atomically may be very difficult or cumbersome in some implementations.
125505 [Objectives 6,8]

125506 It is also necessary to be able to control tracing by trace event type identifier, sometimes called a
125507 trace hook ID. However, there is no mandated set of system trace events, since such trace points
125508 are implementation-defined. The API must not require from the operating system facilities that
125509 are not standard.
125510 [Objectives 6,26]

125511 Trace control must span *fork*( ) and *pthread_create*( ). If not, there will be no way to ensure that an
125512 application's activity is entirely traced. The newly forked child would not be able to turn on its
125513 tracing until after it obtained control after the fork, and trace control externally would be even
125514 more problematic.
125515 [Objective 9]

125516 Since *exec* and *posix_spawn*( ) represent a complete change in the execution of a task (a new
125517 program), trace control need not persist over an *exec* or *posix_spawn*( ).
125518 [Objective 10]

125519 Where trace activities are started on multiple processes, these trace activities should not interfere
125520 with each other.
125521 [Objective 21]

125522 There is no need for a triggering objective, primarily for performance reasons; see also Section
125523 B.2.11.8 (on page 3687), rationale on triggering.
125524 [Objective 11]

125525 It must be possible to determine the origin of each traced event. The process and thread
125526 identifiers for each trace event are needed. Also there was a perceived need for a user-specifiable
125527 origin, but it was felt that this would create too much overhead.
125528 [Objectives 12,14]

An allowance must be made for trace points to come embedded in software components from several different sources and vendors without requiring coordination.
[Objective 13]

There is a requirement to be able to uniquely identify trace points that may have the same trace stream identifier. This is only necessary when a trace report is produced.
[Objectives 12,14]

Tracing is a very performance-sensitive activity, and will therefore likely be implemented at a low level within the system. Hence the interface must not mandate any particular buffering or storage method. Therefore, a standard API is needed to read a trace stream. Also the interface must not mandate the format of the trace data, and the interface must not assume a trace storage method. Due to the possibility of a monolithic kernel and the possible presence of multiple processes capable of running trace activities, the two kinds of trace events may be stored in two separate streams for performance reasons. A mandatory dump mechanism, common in some existing practice, has been avoided to allow the implementation of this set of functions on small realtime profiles for which the concept of a file system is not defined. The trace API calls should be implemented as macros.
[Objectives 15,16,25,30]

Since a trace facility is a valuable service tool, the output (or log) of a completed trace stream that is written to permanent storage must be readable on other systems of the type that produced the trace log. Note that there is no objective to be able to interpret a trace log that was not successfully completed.
[Objectives 17,18,19]

For trace streams written to permanent storage, a way to specify the destination of the trace stream is needed.
[Objective 20]

There is a requirement to be able to depend on the ordering of trace events up to some implementation-defined time interval. For example, there is a need to know the time period during which, if trace events are closer together, their ordering is unspecified. Events that occur within an interval smaller than this resolution may or may not be read back in the correct order.
[Objective 24]

The application should be able to know how much data can be traced. When trace event types can be filtered, the application should be able to specify the approximate maximum amount of data that will be traced in a trace event so resources can be more efficiently allocated.
[Objectives 28,29]

Users should not be able to trace data to which they would not normally have access. System trace events corresponding to a process/thread should be associated with the ownership of that process/thread.
[Objective 31]

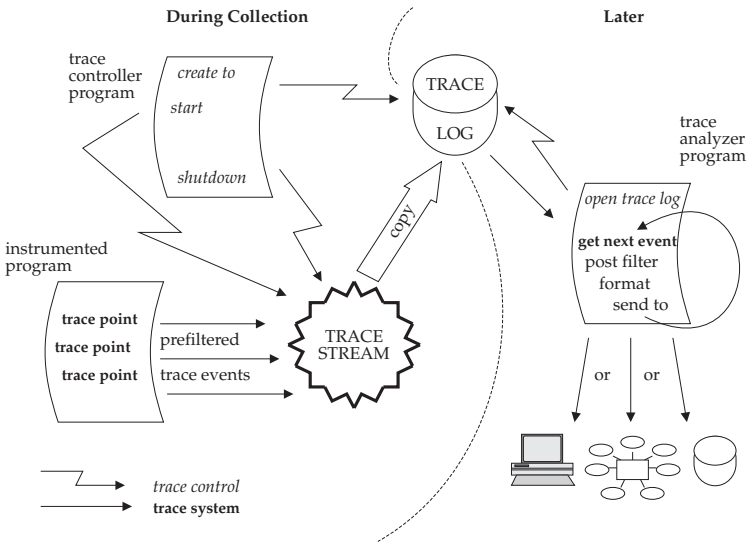
125567 *B.2.11.2 Trace Model*

125568 **Introduction**

125569 The model is based on two base entities: the ``Trace Stream'' and the ``Trace Log'', and a recorded
125570 unit called the ``Trace Event''. The possibility of using Trace Streams and Trace Logs separately
125571 gives two use dimensions and solves both the performance issue and the full-information
125572 system issue. In the case of a trace stream without log, specific information, although reduced in
125573 quantity, is required to be registered, in a possibly small realtime system, with as little overhead
125574 as possible. The Trace Log option has been added for small realtime systems. In the case of a
125575 trace stream with log, considerable complex application-specific information needs to be
125576 collected.

125577 **Trace Model Description**

125578 The trace model can be examined for three different subfunctions: Application Instrumentation,
125579 Trace Operation Control, and Trace Analysis.



125580 **Figure B-2** Trace System Overview: for Offline Analysis

125581 Each of these subfunctions requires specific characteristics of the trace mechanism API.

125582 Application Instrumentation

125583 When instrumenting an application, the programmer is not concerned about the future use
125584 of the trace events in the trace stream or the trace log, the full policy of the trace stream, or
125585 the eventual pre-filtering of trace events. But he is concerned about the correct
125586 determination of the specific trace event type identifier, regardless of how many
125587 independent libraries are used in the same user application; see Figure B-2 and Figure B-3
125588 (on page 3670).

125589 This trace API provides the necessary operations to accomplish this subfunction. This is
125590 done by providing functions to associate a programmer-defined name with an
125591 implementation-defined trace event type identifier (see the *posix_trace_eventid_open*( )
125592 function), and to send this trace event into a potential trace stream (see the
125593 *posix_trace_event*( ) function).

125594 Trace Operation Control

125595 When controlling the recording of trace events in a trace stream, the programmer is
125596 concerned with the correct initialization of the trace mechanism (that is, the sizing of the
125597 trace stream), the correct retention of trace events in a permanent storage, the correct
125598 dynamic recording of trace events, and so on.

125599 This trace API provides the necessary material to permit this efficiently. This is done by
125600 providing functions to initialize a new trace stream, and optionally a trace log:

125601 ‡ráce Stream Attributes Object Initialization (see *posix_trace_attr_init*( ))

125602 ‡únctions to Retrieve or Set Information About a Trace Stream (see
125603 *posix_trace_attr_getgenversion*( ))

125604 ‡únctions to Retrieve or Set the Behavior of a Trace Stream (see
125605 *posix_trace_attr_getinherited*( ))

125606 ‡únctions to Retrieve or Set Trace Stream Size Attributes (see
125607 *posix_trace_attr_getmaxusereventsize*( ))

125608 ‡ráce Stream Initialization, Flush, and Shutdown from a Process (see
125609 *posix_trace_create*( ))

125610 ‡léar Trace Stream and Trace Log (see *posix_trace_clear*( ))

125611 To select the trace event types that are to be traced:

125612 ‡ áMpulate Trace Event Type Identifier (see *posix_trace_trid_eventid_open*( ))

125613 ‡terate over a Mapping of Trace Event Type (see *posix_trace_eventtypelist_getnext_id*( ))

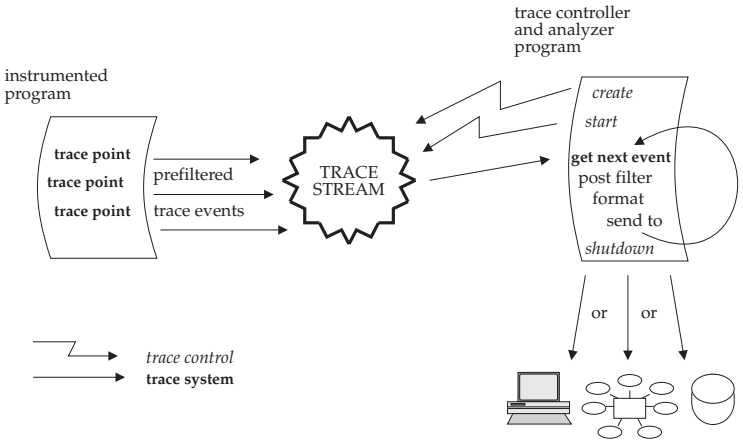
125614 ‡ áMpulate Trace Event Type Sets (see *posix_trace_eventset_empty*( ))

125615 ‡et Filter of an Initialized Trace Stream (see *posix_trace_set_filter*( ))

125616 To control the execution of an active trace stream:

125617 ‡ráce Start and Stop (see *posix_trace_start*( ))

125618 ‡únctions to Retrieve the Trace Attributes or Trace Statuses (see
125619 *posix_trace_get_attr*( ))



125620 **Figure B-3** Trace System Overview: for Online Analysis

125621 Trace Analysis

125622 Once correctly recorded, on permanent storage or not, an ultimate activity consists of the
125623 analysis of the recorded information. If the recorded data is on permanent storage, a
125624 specific open operation is required to associate a trace stream to a trace log.

125625 The first intent of the group was to request the presence of a system identification structure
125626 in the trace stream attribute. This was, for the application, to allow some portable way to
125627 process the recorded information. However, there is no requirement that the **utsname**
125628 structure, on which this system identification was based, be portable from one machine to
125629 another, so the contents of the attribute cannot be interpreted correctly by an application
125630 conforming to POSIX.1-2017.

125631 This modification has been incorporated and requests that some unspecified information
125632 be recorded in the trace log in order to fail opening it if the analysis process and the
125633 controller process were running in different types of machine, but does not request that
125634 this information be accessible to the application. This modification has implied a
125635 modification in the *posix_trace_open*( ) function error code returns.

125636 This trace API provides functions to:

125637 ‡ xtEact trace stream identification attributes (see *posix_trace_attr_getgenversion*( ))

125638 ‡ xtEact trace stream behavior attributes (see *posix_trace_attr_getinherited*( ))

125639 ‡ xtEact trace event, stream, and log size attributes (see
125640 *posix_trace_attr_getmaxusereventsize*( ))

125641 ‡ o'dk up trace event type names (see *posix_trace_eventid_get_name*( ))

125642 ‡ te'rhate over trace event type identifiers (see *posix_trace_eventtypelist_getnext_id*( ))

125643 ‡ p'eO, rewind, and close a trace log (see *posix_trace_open*( ))

125644 ‡ e'akR trace stream attributes and status (see *posix_trace_get_attr*( ))

125645 ‡ e'akR trace events (see *posix_trace_getnext_event*( ))

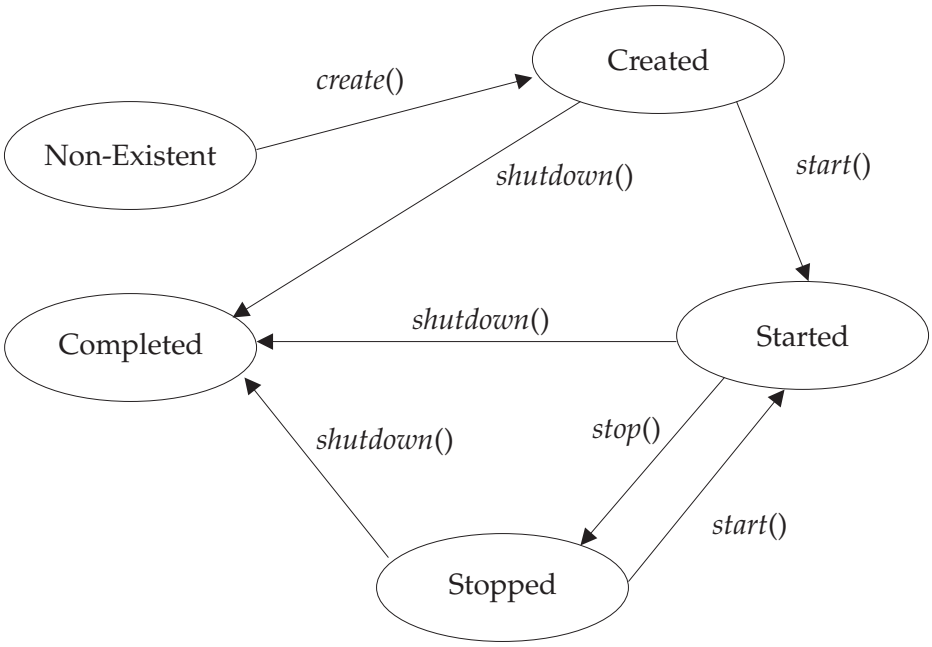
125646 Due to the following two reasons:

125647 1. The requirement that the trace system must not add unacceptable overhead to the traced
125648 process and so that the trace event point execution must be fast

125649 2. The traced application does not care about tracing errors

125650 the trace system cannot return any internal error to the application. Internal error conditions can
125651 range from unrecoverable errors that will force the active trace stream to abort, to small errors
125652 that can affect the quality of tracing without aborting the trace stream. The group decided to
125653 define a system trace event to report to the analysis process such internal errors. It is not the
125654 intention of POSIX.1-2017 to require an implementation to report an internal error that corrupts
125655 or terminates tracing operation. The implementor is free to decide which internal documented
125656 errors, if any, the trace system is able to report.

125657 **States of a Trace Stream**



125658 **Figure B-4** Trace System Overview: States of a Trace Stream

125659 Figure B-4 shows the different states an active trace stream passes through. After the
125660 *posix_trace_create*( ) function call, a trace stream becomes CREATED and a trace stream is
125661 associated for the future collection of trace events. The status of the trace stream is
125662 POSIX_TRACE_SUSPENDED. The state becomes STARTED after a call to the *posix_trace_start*( )
125663 function, and the status becomes POSIX_TRACE_RUNNING. In this state, all trace events that
125664 are not filtered out will be stored into the trace stream. After a call to *posix_trace_stop*( ), the trace
125665 stream becomes STOPPED (and the status POSIX_TRACE_SUSPENDED). In this state, no new
125666 trace events will be recorded in the trace stream, but previously recorded trace events may
125667 continue to be read.

125668 After a call to *posix_trace_shutdown*( ), the trace stream is in the state COMPLETED. The trace
125669 stream no longer exists but, if the Trace Log option is supported, all the information contained in
125670 it has been logged. If a log object has not been associated with the trace stream at the creation, it
125671 is the responsibility of the trace controller process to not shut the trace stream down while trace
125672 events remain to be read in the stream.

125673 **Tracing All Processes**

125674 Some implementations have a tracing subsystem with the ability to trace all processes. This is
125675 useful to debug some types of device drivers such as those for ATM or X25 adapters. These
125676 types of adapters are used by several independent processes, that are not issued from the same
125677 process.

125678 The POSIX trace interface does not define any constant or option to create a trace stream tracing
125679 all processes. POSIX.1 does not prevent this type of implementation and an implementor is free
125680 to add this capability. Nevertheless, the trace interface allows tracing of all the system trace
125681 events and all the processes issued from the same process.

125682 If such a tracing system capability has to be implemented, when a trace stream is created, it is
125683 recommended that a constant named POSIX_TRACE_ALLPROC be used instead of the process
125684 identifier in the argument of the *posix_trace_create*( ) or *posix_trace_create_withlog*( ) function. A
125685 possible value for POSIX_TRACE_ALLPROC may be –1 instead of a real process identifier.

125686 The implementor has to be aware that there is some impact on the tracing behavior as defined in
125687 the POSIX trace interface. For example:

125688 If the default value for the inheritance attribute is set to
125689 POSIX_TRACE_CLOSE_FOR_CHILD, the implementation has to stop tracing for the child
125690 process.

125691 The trace controller which is creating this type of trace stream must have the appropriate
125692 privilege to trace all the processes.

125693 **Trace Storage**

125694 The model is based on two types of trace events: system trace events and user-defined trace
125695 events. The internal representation of trace events is implementation-defined, and so the
125696 implementor is free to choose the more suitable, practical, and efficient way to design the
125697 internal management of trace events. For the timestamping operation, the model does not
125698 impose the CLOCK_REALTIME or any other clock. The buffering allocation and operation
125699 follow the same principle. The implementor is free to use one or more buffers to record trace
125700 events; the interface assumes only a logical trace stream of sequentially recorded trace events.
125701 Regarding flushing of trace events, the interface allows the definition of a trace log object which
125702 typically can be a file. But the group was also aware of defining functions to permit the use of
125703 this interface in small realtime systems, which may not have general file system capabilities. For
125704 instance, the three functions *posix_trace_getnext_event*( ) (blocking),
125705 *posix_trace_timedgetnext_event*( ) (blocking with timeout), and *posix_trace_trygetnext_event*( ) (non-
125706 blocking) are proposed to read the recorded trace events.

125707 The policy to be used when the trace stream becomes full also relies on common practice:

125708 For an active trace stream, the POSIX_TRACE_LOOP trace stream policy permits
125709 automatic overrun (overwrite of oldest trace events) while waiting for some user-defined
125710 condition to cause tracing to stop. By contrast, the POSIX_TRACE_UNTIL_FULL trace
125711 stream policy requires the system to stop tracing when the trace stream is full. However, if
125712 the trace stream that is full is at least partially emptied by a call to the *posix_trace_flush*( )
125713 function or by calls to the *posix_trace_getnext_event*( ) function, the trace system will
125714 automatically resume tracing.

125715 If the Trace Log option is supported, the operation of the POSIX_TRACE_FLUSH policy is
125716 an extension of the POSIX_TRACE_UNTIL_FULL policy. The automatic free operation (by
125717 flushing to the associated trace log) is added.

125718 If a log is associated with the trace stream and this log is a regular file, these policies also
125719 apply for the log. One more policy, POSIX_TRACE_APPEND, is defined to allow
125720 indefinite extension of the log. Since the log destination can be any device or pseudo-
125721 device, the implementation may not be able to manipulate the destination as required by
125722 POSIX.1-2017. For this reason, the behavior of the log full policy may be unspecified
125723 depending on the trace log type.

125724 The current trace interface does not define a service to preallocate space for a trace log file,
125725 because this space can be preallocated by means of a call to the *posix_fallocate*( ) function.
125726 This function could be called after the file has been opened, but before the trace stream is
125727 created. The *posix_fallocate*( ) function ensures that any required storage for regular file data
125728 is allocated on the file system storage media. If *posix_fallocate*( ) returns successfully,

125729 subsequent writes to the specified file data will not fail due to the lack of free space on the
125730 file system storage media. Besides trace events, a trace stream also includes trace attributes
125731 and the mapping from trace event names to trace event type identifiers. The implementor
125732 is free to choose how to store the trace attributes and the trace event type map, but must
125733 ensure that this information is not lost when a trace stream overrun occurs.

125734 *B.2.11.3 Trace Programming Examples*

125735 Several programming examples are presented to show the code of the different possible
125736 subfunctions using a trace subsystem. All these programs need to include the **<trace.h>** header.
125737 In the examples shown, error checking is omitted for more simplicity.

125738 **Trace Operation Control**

125739 These examples show the creation of a trace stream for another process; one which is already
125740 trace instrumented. All the default trace stream attributes are used to simplify programming in
125741 the first example. The second example shows more possibilities.

125742 **First Example**

```
125743 /* Caution. Error checks omitted */
125744 {
125745     trace_attr_t attr;
125746     pid_t pid = traced_process_pid;
125747     int fd;
125748     trace_id_t trid;

125749     - - - - - -
125750     /* Initialize trace stream attributes */
125751     posix_trace_attr_init(&attr);
125752     /* Open a trace log */
125753     fd=open("/tmp/mytracelog",...);
125754     /*
125755      * Create a new trace associated with a log
125756      * and with default attributes
125757      */

125758     posix_trace_create_withlog(pid, &attr, fd, &trid);

125759     /* Trace attribute structure can now be destroyed */
125760     posix_trace_attr_destroy(&attr);
125761     /* Start of trace event recording */
125762     posix_trace_start(trid);
125763     - - - - - -
125764     - - - - - -
125765     /* Duration of tracing */
125766     - - - - - -
125767     - - - - - -
125768     /* Stop and shutdown of trace activity */
125769     posix_trace_shutdown(trid);
125770     - - - - - -
125771 }
```

Second Example

Between the initialization of the trace stream attributes and the creation of the trace stream, these trace stream attributes may be modified; see Trace Stream Attribute Manipulation (on page 3678) for a specific programming example. Between the creation and the start of the trace stream, the event filter may be set; after the trace stream is started, the event filter may be changed. The setting of an event set and the change of a filter is shown in Create a Trace Event Type Set and Change the Trace Event Type Filter (on page 3679).

```
/* Caution. Error checks omitted */
{
    trace_attr_t attr;
    pid_t pid = traced_process_pid;
    int fd;
    trace_id_t trid;
    - - - - - -
    /* Initialize trace stream attributes */
    posix_trace_attr_init(&attr);
    /* Attr default may be changed at this place; see example */
    - - - - - -
    /* Create and open a trace log with R/W user access */
    fd=open("/tmp/mytracelog",O_WRONLY|O_CREAT,S_IRUSR|S_IWUSR);
    /* Create a new trace associated with a log */
    posix_trace_create_withlog(pid, &attr, fd, &trid);
    /*
     * If the Trace Filter option is supported
     * trace event type filter default may be changed at this place;
     * see example about changing the trace event type filter
     */
    posix_trace_start(trid);
    - - - - - -

    /*
     * If you have an uninteresting part of the application
     * you can stop temporarily.
     *
     * posix_trace_stop(trid);
     * - - - - - -
     * - - - - - -
     * posix_trace_start(trid);
     */
    - - - - - -
    /*
     * If the Trace Filter option is supported
     * the current trace event type filter can be changed
     * at any time (see example about how to set
     * a trace event type filter)
     */
    - - - - - -

    /* Stop the recording of trace events */
    posix_trace_stop(trid);
    /* Shutdown the trace stream */
    posix_trace_shutdown(trid);
    /*
```

```
         * Destroy trace stream attributes; attr structure may have
         * been used during tracing to fetch the attributes
         */
        posix_trace_attr_destroy(&attr);
        - - - - - -
}
```

Application Instrumentation

This example shows an instrumented application. The code is included in a block of instructions, perhaps a function from a library. Possibly in an initialization part of the instrumented application, two user trace events names are mapped to two trace event type identifiers (function *posix_trace_eventid_open*()). Then two trace points are programmed.

```
/* Caution. Error checks omitted */
{
    trace_event_id_t eventid1, eventid2;
    - - - - - -
    /* Initialization of two trace event type ids */
    posix_trace_eventid_open("my_first_event",&eventid1);
    posix_trace_eventid_open("my_second_event",&eventid2);
    - - - - - -
    - - - - - -
    - - - - - -
    /* Trace point */
    posix_trace_event(eventid1,NULL,0);
    - - - - - -
    /* Trace point */
    posix_trace_event(eventid2,NULL,0);
    - - - - - -
}
```

Trace Analyzer

This example shows the manipulation of a trace log resulting from the dumping of a completed trace stream. All the default attributes are used to simplify programming, and data associated with a trace event is not shown in the first example. The second example shows more possibilities.

First Example

```
/* Caution. Error checks omitted */
{
    int fd;
    trace_id_t trid;
    posix_trace_event_info trace_event;
    char trace_event_name[TRACE_EVENT_NAME_MAX];
    int return_value;
    size_t returndatasize;
    int lost_event_number;

    - - - - - -

    /* Open an existing trace log */
    fd=open("/tmp/tracelog", O_RDONLY);
```

```
        /* Open a trace stream on the open log */
        posix_trace_open(fd, &trid);
        /* Read a trace event */
        posix_trace_getnext_event(trid, &trace_event,
            NULL, 0, &returndatasize,&return_value);

        /* Read and print all trace event names out in a loop */
        while (return_value == NULL)
        {
            /*
             * Get the name of the trace event associated
             * with trid trace ID
             */
            posix_trace_eventid_get_name(trid, trace_event.event_id,
                trace_event_name);
            /* Print the trace event name out */
            printf("%s\n",trace_event_name);
            /* Read a trace event */
            posix_trace_getnext_event(trid, &trace_event,
                NULL, 0, &returndatasize,&return_value);
        }

        /* Close the trace stream */
        posix_trace_close(trid);
        /* Close the trace log */
        close(fd);
    }
```

Second Example

The complete example includes the two other examples in Retrieve Information from a Trace Log (on page 3680) and in Retrieve the List of Trace Event Types Used in a Trace Log (on page 3681). For example, the *maxdatasize* variable is set in Retrieve the List of Trace Event Types Used in a Trace Log (on page 3681).

```
/* Caution. Error checks omitted */
{
    int fd;
    trace_id_t trid;
    posix_trace_event_info trace_event;
    char trace_event_name[TRACE_EVENT_NAME_MAX];
    char * data;
    size_t maxdatasize=1024, returndatasize;
    int return_value;
    - - - - - -

    /* Open an existing trace log */
    fd=open("/tmp/tracelog", O_RDONLY);
    /* Open a trace stream on the open log */
    posix_trace_open( fd, &trid);
    /*
     * Retrieve information about the trace stream which
     * was dumped in this trace log (see example)
     */
    - - - - - -
```

```
        /* Allocate a buffer for trace event data */
        data=(char *)malloc(maxdatasize);
        /*
         * Retrieve the list of trace events used in this
         * trace log (see example)
         */
        - - - - - -
        /* Read and print all trace event names and data out in a loop */
        while (1)
        {
        posix_trace_getnext_event(trid, &trace_event,
            data, maxdatasize, &returndatasize,&return_value);
            if (return_value != NULL) break;
            /*
             * Get the name of the trace event type associated
             * with trid trace ID
             */
            posix_trace_eventid_get_name(trid, trace_event.event_id,
                trace_event_name);
            {
            int i;
            /* Print the trace event name out */
            printf("%s: ", trace_event_name);
            /* Print the trace event data out */
            for (i=0; i<returndatasize, i++) printf("%02.2X",
                (unsigned char)data[i]);
            printf("\n");
            }
        }
        /* Close the trace stream */
        posix_trace_close(trid);
        /* The buffer data is deallocated */
        free(data);
        /* Now the file can be closed */
        close(fd);
    }
```

Several Programming Manipulations

The following examples show some typical sets of operations needed in some contexts.

Trace Stream Attribute Manipulation

This example shows the manipulation of a trace stream attribute object in order to change the default value provided by a previous *posix_trace_attr_init*() call.

```
    /* Caution. Error checks omitted */
    {
        trace_attr_t attr;
        size_t logsize=100000;
        - - - - - -
        /* Initialize trace stream attributes */
```

```
        posix_trace_attr_init(&attr);
        /* Set the trace name in the attributes structure */
        posix_trace_attr_setname(&attr, "my_trace");
        /* Set the trace full policy */
        posix_trace_attr_setstreamfullpolicy(&attr, POSIX_TRACE_LOOP);
        /* Set the trace log size */
        posix_trace_attr_setlogsize(&attr, logsize);
        - - - - - -
    }
```

Create a Trace Event Type Set and Change the Trace Event Type Filter

This example is valid only if the Trace Event Filter option is supported. This example shows the manipulation of a trace event type set in order to change the trace event type filter for an existing active trace stream, which may be just-created, running, or suspended. Some sets of trace event types are well-known, such as the set of trace event types not associated with a process, some trace event types are just-built trace event types for this trace stream; one trace event type is the predefined trace event error type which is deleted from the trace event type set.

```
    /* Caution. Error checks omitted */
    {
        trace_id_t trid = existing_trace;
        trace_event_set_t set;
        trace_event_id_t trace_event1, trace_event2;
        - - - - - -
        /* Initialize to an empty set of trace event types */
        /* (not strictly required because posix_trace_event_set_fill() */
        /* will ignore the prior contents of the event set.) */
        posix_trace_eventset_emptyset(&set);
        /*
         * Fill the set with all system trace events
         * not associated with a process
         */
        posix_trace_eventset_fill(&set, POSIX_TRACE_WOPID_EVENTS);
        /*
         * Get the trace event type identifier of the known trace event name
         * my_first_event for the trid trace stream
         */
        posix_trace_trid_eventid_open(trid, "my_first_event", &trace_event1);
        /* Add the set with this trace event type identifier */
        posix_trace_eventset_add_event(trace_event1, &set);
        /*
         * Get the trace event type identifier of the known trace event name
         * my_second_event for the trid trace stream
         */
        posix_trace_trid_eventid_open(trid, "my_second_event", &trace_event2);
        /* Add the set with this trace event type identifier */
        posix_trace_eventset_add_event(trace_event2, &set);
        - - - - - -
        /* Delete the system trace event POSIX_TRACE_ERROR from the set */
        posix_trace_eventset_del_event(POSIX_TRACE_ERROR, &set);
        - - - - - -
```

```
        /* Modify the trace stream filter making it equal to the new set */
        posix_trace_set_filter(trid, &set, POSIX_TRACE_SET_EVENTSET);
        - - - - - -
        /*
         * Now trace_event1, trace_event2, and all system trace event types
         * not associated with a process, except for the POSIX_TRACE_ERROR
         * system trace event type, are filtered out of (not recorded in) the
         * existing trace stream.
         */
    }
```

Retrieve Information from a Trace Log

This example shows how to extract information from a trace log, the dump of a trace stream. This code:

Asks if the trace stream has lost trace events

Extracts the information about the version of the trace subsystem which generated this trace log

Retrieves the maximum size of trace event data; this may be used to dynamically allocate an array for extracting trace event data from the trace log without overflow

```
/* Caution. Error checks omitted */
{
    struct posix_trace_status_info statusinfo;
    trace_attr_t attr;
    trace_id_t trid = existing_trace;
    size_t maxdatasize;
    char genversion[TRACE_NAME_MAX];
    - - - - - -
    /* Get the trace stream status */
    posix_trace_get_status(trid, &statusinfo);
    /* Detect an overrun condition */
    if (statusinfo.posix_stream_overrun_status == POSIX_TRACE_OVERRUN)
        printf("trace events have been lost\n");
    /* Get attributes from the trid trace stream */
    posix_trace_get_attr(trid, &attr);
    /* Get the trace generation version from the attributes */
    posix_trace_attr_getgenversion(&attr, genversion);
    /* Print the trace generation version out */
    printf("Information about Trace Generator:%s\n",genversion);
    /* Get the trace event max data size from the attributes */
    posix_trace_attr_getmaxdatasize(&attr, &maxdatasize);
    /* Print the trace event max data size out */
    printf("Maximum size of associated data:%d\n",maxdatasize);
    /* Destroy the trace stream attributes */
    posix_trace_attr_destroy(&attr);
}
```

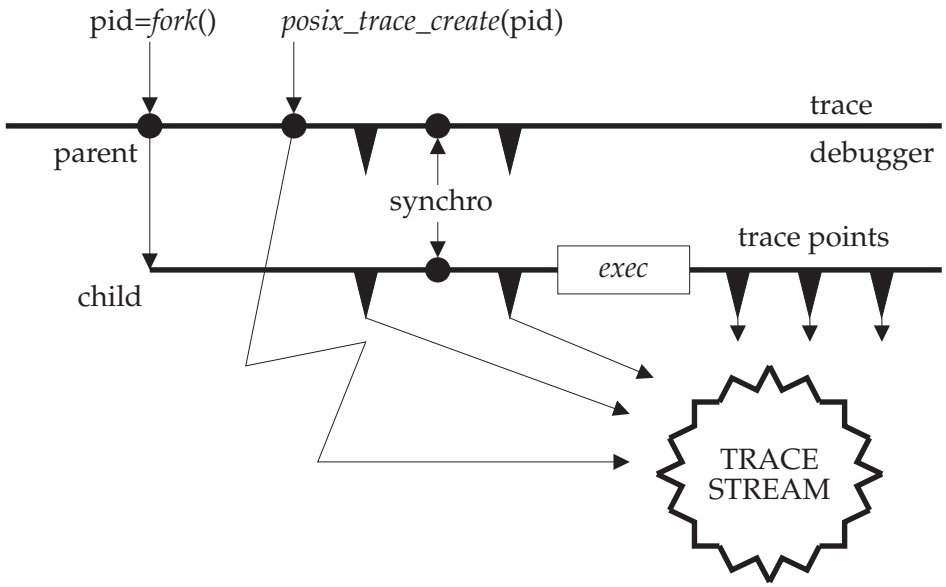
Retrieve the List of Trace Event Types Used in a Trace Log

This example shows the retrieval of a trace stream's trace event type list. This operation may be very useful if you are interested only in tracking the type of trace events in a trace log.

```
/* Caution. Error checks omitted */
{
    trace_id_t trid = existing_trace;
    trace_event_id_t event_id;
    char event_name[TRACE_EVENT_NAME_MAX];
    int return_value;
    - - - - - -

    /*
     * In a loop print all existing trace event names out
     * for the trid trace stream
     */
    while (1)
    {
        posix_trace_eventtypelist_getnext_id(trid, &event_id
            &return_value);
        if (return_value != NULL) break;
        /*
         * Get the name of the trace event associated
         * with trid trace ID
         */
        posix_trace_eventid_get_name(trid, event_id, event_name);
        /* Print the name out */
        printf("%s\n", event_name);
    }
}
```

126086 *B.2.11.4 Rationale on Trace for Debugging*



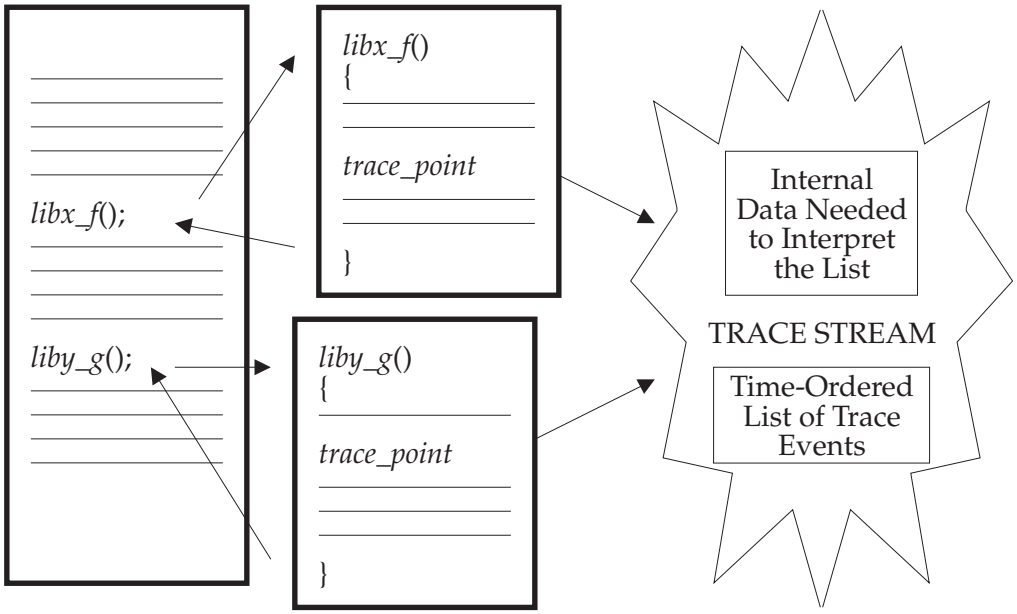
126087 **Figure B-5** Trace Another Process

126088 Among the different possibilities offered by the trace interface defined in POSIX.1-2017, the
126089 debugging of an application is the most interesting one. Typical operations in the controlling
126090 debugger process are to filter trace event types, to get trace events from the trace stream, to stop
126091 the trace stream when the debugged process is executing uninteresting code, to start the trace
126092 stream when some interesting point is reached, and so on. The interface defined in POSIX.1-2017
126093 should define all the necessary base functions to allow this dynamic debug handling.

126094 Figure B-5 shows an example in which the trace stream is created after the call to the *fork*()
126095 function. If the user does not want to lose trace events, some synchronization mechanism
126096 (represented in the figure) may be needed before calling the *exec*() function, to give the parent a
126097 chance to create the trace stream before the child begins the execution of its trace points.

126098 *B.2.11.5 Rationale on Trace Event Type Name Space*

126099 At first, the working group was in favor of the representation of a trace event type by an integer
126100 (*event_name*). It seems that existing practice shows the weakness of such a representation. The
126101 collision of trace event types is the main problem that cannot be simply resolved using this sort
126102 of representation. Suppose, for example, that a third party designs an instrumented library. The
126103 user does not have the source of this library and wants to trace his application which uses in
126104 some part the third-party library. There is no means for him to know what are the trace event
126105 types used in the instrumented library so he has some chance of duplicating some of them and
126106 thus to obtain a contaminated tracing of his application.



126107 **Figure B-6** Trace Name Space Overview: With Third-Party Library

126108 There are requirements to allow program images containing pieces from various vendors to be
126109 traced without also requiring those of any other vendors to coordinate their uses of the trace
126110 facility, and especially the naming of their various trace event types and trace point IDs. The
126111 chosen solution is to provide a very large name space, large enough so that the individual
126112 vendors can give their trace types and tracepoint IDs sufficiently long and descriptive names
126113 making the occurrence of collisions quite unlikely. The probability of collision is thus made
126114 sufficiently low so that the problem may, as a practical matter, be ignored. By requirement, the
126115 consequence of collisions will be a slight ambiguity in the trace streams; tracing will continue in
126116 spite of collisions and ambiguities. ``The show must go on''. The *posix_prog_address* member of
126117 the **posix_trace_event_info** structure is used to allow trace streams to be unambiguously
126118 interpreted, despite the fact that trace event types and trace event names need not be unique.

126119 The *posix_trace_eventid_open*() function is required to allow the instrumented third-party library
126120 to get a valid trace event type identifier for its trace event names. This operation is, somehow,
126121 an allocation, and the group was aware of proposing some deallocation mechanism which the
126122 instrumented application could use to recover the resources used by a trace event type identifier.
126123 This would have given the instrumented application the benefit of being capable of reusing a
126124 possible minimum set of trace event type identifiers, but also the inconvenience to have,
126125 possibly in the same trace stream, one trace event type identifier identifying two different trace
126126 event types. After some discussions the group decided to not define such a function which
126127 would make this API thicker for little benefit, the user having always the possibility of adding
126128 identification information in the *data* member of the trace event structure.

126129 The set of the trace event type identifiers the controlling process wants to filter out is initialized
126130 in the trace mechanism using the function *posix_trace_set_filter*(), setting the arguments
126131 according to the definitions explained in *posix_trace_set_filter*(). This operation can be done
126132 statically (when the trace is in the STOPPED state) or dynamically (when the trace is in the
126133 STARTED state). The preparation of the filter is normally done using the function defined in
126134 *posix_trace_eventtypelist_getnext_id*() and eventually the function
126135 *posix_trace_eventtypelist_rewind*() in order to know (before the recording) the list of the potential

126136 set of trace event types that can be recorded. In the case of an active trace stream, this list may
126137 not be exhaustive. Actually, the target process may not have yet called the function
126138 *posix_trace_eventid_open*(). But it is a common practice, for a controlling process, to prepare the
126139 filtering of a future trace stream before its start. Therefore the user must have a way to get the
126140 trace event type identifier corresponding to a well-known trace event name before its future
126141 association by the pre-cited function. This is done by calling the *posix_trace_trid_eventid_open*()
126142 function, given the trace stream identifier and the trace name, and described hereafter. Because
126143 this trace event type identifier is associated with a trace stream identifier, where a unique
126144 process has initialized two or more traces, the implementation is expected to return the same
126145 trace event type identifier for successive calls to *posix_trace_trid_eventid_open*() with different
126146 trace stream identifiers. The *posix_trace_eventid_get_name*() function is used by the controller
126147 process to identify, by the name, the trace event type returned by a call to the
126148 *posix_trace_eventtypelist_getnext_id*() function.

126149 Afterwards, the set of trace event types is constructed using the functions defined in
126150 *posix_trace_eventset_empty*(), *posix_trace_eventset_fill*(), *posix_trace_eventset_add*(), and
126151 *posix_trace_eventset_del*().

126152 A set of functions is provided devoted to the manipulation of the trace event type identifier and
126153 names for an active trace stream. All these functions require the trace stream identifier argument
126154 as the first parameter. The opacity of the trace event type identifier implies that the user cannot
126155 associate directly its well-known trace event name with the system-associated trace event type
126156 identifier.

126157 The *posix_trace_trid_eventid_open*() function allows the application to get the system trace event
126158 type identifier back from the system, given its well-known trace event name. This function is
126159 useful only when a controlling process needs to specify specific events to be filtered.

126160 The *posix_trace_eventid_get_name*() function allows the application to obtain a trace event name
126161 given its trace event type identifier. One possible use of this function is to identify the type of a
126162 trace event retrieved from the trace stream, and print it. The easiest way to implement this
126163 requirement, is to use a single trace event type map for all the processes whose maps are
126164 required to be identical. A more difficult way is to attempt to keep multiple maps identical at
126165 every call to *posix_trace_eventid_open*() and *posix_trace_trid_eventid_open*().

126166 *B.2.11.6 Rationale on Trace Events Type Filtering*

126167 The most basic rationale for runtime and pre-registration filtering (selection/rejection) of trace
126168 event types is to prevent choking of the trace collection facility, and/or overloading of the
126169 computer system. Any worthwhile trace facility can bring even the largest computer to its
126170 knees. Otherwise, everything would be recorded and filtered after the fact; it would be much
126171 simpler, but impractical.

126172 To achieve debugging, measurement, or whatever the purpose of tracing, the filtering of trace
126173 event types is an important part of trace analysis. Due to the fact that the trace events are put
126174 into a trace stream and probably logged afterwards into a file, different levels of filtering ‡that
126175 is, rejection of trace event types—are possible.

126176 **Filtering of Trace Event Types Before Tracing**

126177 This function, represented by the *posix_trace_set_filter*( ) function in POSIX.1-2017 (see
126178 *posix_trace_set_filter*( )), selects, before or during tracing, the set of trace event types to be filtered
126179 out. It should be possible also (as OSF suggested in their ETAP trace specifications) to select the
126180 kernel trace event types to be traced in a system-wide fashion. These two functionalities are
126181 called the pre-filtering of trace event types.

126182 The restriction on the actual type used for the **trace_event_set_t** type is intended to guarantee
126183 that these objects can always be assigned, have their address taken, and be passed by value as
126184 parameters. It is not intended that this type be a structure including pointers to other data
126185 structures, as that could impact the portability of applications performing such operations. A
126186 reasonable implementation could be a structure containing an array of integer types.

126187 **Filtering of Trace Event Types at Runtime**

126188 It is possible to build this functionality using the *posix_trace_set_filter*( ) function. A privileged
126189 process or a privileged thread can get trace events from the trace stream of another process or
126190 thread, and thus specify the type of trace events to record into a file, using implementation-
126191 defined methods and interfaces. This functionality, called inline filtering of trace event types, is
126192 used for runtime analysis of trace streams.

126193 **Post-Mortem Filtering of Trace Event Types**

126194 The word ``post-mortem'' is used here to indicate that some unanticipated situation occurs
126195 during execution that does not permit a pre or inline filtering of trace events and that it is
126196 necessary to record all trace event types to have a chance to discover the problem afterwards.
126197 When the program stops, all the trace events recorded previously can be analyzed in order to
126198 find the solution. This functionality could be named the post-filtering of trace event types.

126199 **Discussions about Trace Event Type Filtering**

126200 After long discussions with the parties involved in the process of defining the trace interface, it
126201 seems that the sensitivity to the filtering problem is different, but everybody agrees that the level
126202 of the overhead introduced during the tracing operation depends on the filtering method
126203 elected. If the time that it takes the trace event to be recorded can be neglected, the overhead
126204 introduced by the filtering process can be classified as follows:

126205 Pre-filtering System and process/thread-level overhead

126206 Inline-filtering Process/thread-level overhead

126207 Post-filtering No overhead; done offline

126208 The pre-filtering could be named ``critical realtime'' filtering in the sense that the filtering of
126209 trace event type is manageable at the user level so the user can lower to a minimum the filtering
126210 overhead at some user selected level of priority for the inline filtering, or delay the filtering to
126211 after execution for the post-filtering. The counterpart of this solution is that the size of the trace
126212 stream must be sufficient to record all the trace events. The advantage of the pre-filtering is that
126213 the utilization of the trace stream is optimized.

126214 Only pre-filtering is defined by POSIX.1-2017. However, great care must be taken in specifying
126215 pre-filtering, so that it does not impose unacceptable overhead. Moreover, it is necessary to
126216 isolate all the functionality relative to the pre-filtering.

126217 The result of this rationale is to define a new option, the Trace Event Filter option, not
126218 necessarily implemented in small realtime systems, where system overhead is minimized to the
126219 extent possible.

B.2.11.7 Tracing, pthread API

The objective to be able to control tracing for individual threads may be in conflict with the efficiency expected in threads with a *contentionscope* attribute of PTHREAD_SCOPE_PROCESS. For these threads, context switches from one thread that has tracing enabled to another thread that has tracing disabled may require a kernel call to inform the kernel whether it has to trace system events executed by that thread or not. For this reason, it was proposed that the ability to enable or disable tracing for PTHREAD_SCOPE_PROCESS threads be made optional, through the introduction of a Trace Scope Process option. A trace implementation which did not implement the Trace Scope Process option would not honor the tracing-state attribute of a thread with PTHREAD_SCOPE_PROCESS; it would, however, honor the tracing-state attribute of a thread with PTHREAD_SCOPE_SYSTEM. This proposal was rejected as:

1. Removing desired functionality (per-thread trace control)
2. Introducing counter-intuitive behavior for the tracing-state attribute
3. Mixing logically orthogonal ideas (thread scheduling and thread tracing) [Objective 4]

Finally, to solve this complex issue, this API does not provide *pthread_gettracingstate*(), *pthread_settracingstate*(), *pthread_attr_gettracingstate*(), and *pthread_attr_settracingstate*() interfaces. These interfaces force the thread implementation to add to the weight of the thread and cause a revision of the threads libraries, just to support tracing. Worse yet, *posix_trace_event*() must always test this per-thread variable even in the common case where it is not used at all. Per-thread tracing is easy to implement using existing interfaces where necessary; see the following example.

Example

```
/* Caution. Error checks omitted */
static pthread_key_t my_key;
static trace_event_id_t my_event_id;
static pthread_once_t my_once = PTHREAD_ONCE_INIT;

void my_init(void)
{
    (void) pthread_key_create(&my_key, NULL);
    (void) posix_trace_eventid_open("my", &my_event_id);
}

int get_trace_flag(void)
{
    pthread_once(&my_once, my_init);
    return (pthread_getspecific(my_key) != NULL);
}

void set_trace_flag(int f)
{
    pthread_once(&my_once, my_init);
    pthread_setspecific(my_key, f? &my_event_id: NULL);
}

fn()
{
    if (get_trace_flag())
        posix_trace_event(my_event_id, ...)
}
```

126267 The above example does not implement third-party state setting.

126268 Lastly, per-thread tracing works poorly for threads with PTHREAD_SCOPE_PROCESS
126269 contention scope. These ``library'' threads have minimal interaction with the kernel and would
126270 have to explicitly set the attributes whenever they are context switched to a new kernel thread in
126271 order to trace system events. Such state was explicitly avoided in POSIX threads to keep
126272 PTHREAD_SCOPE_PROCESS threads lightweight.

126273 The reason that keeping PTHREAD_SCOPE_PROCESS threads lightweight is important is that
126274 such threads can be used not just for simple multi-processors but also for co-routine style
126275 programming (such as discrete event simulation) without inventing a new threads paradigm.
126276 Adding extra runtime cost to thread context switches will make using POSIX threads less
126277 attractive in these situations.

126278 *B.2.11.8 Rationale on Triggering*

126279 The ability to start or stop tracing based on the occurrence of specific trace event types has been
126280 proposed as a parallel to similar functionality appearing in logic analyzers. Such triggering, in
126281 order to be very useful, should be based not only on the trace event type, but on trace event-
126282 specific data, including tests of user-specified fields for matching or threshold values.

126283 Such a facility is unnecessary where the buffering of the stream is not a constraint, since such
126284 checks can be performed offline during post-mortem analysis.

126285 For example, a large system could incorporate a daemon utility to collect the trace records from
126286 memory buffers and spool them to secondary storage for later analysis. In the instances where
126287 resources are truly limited, such as embedded applications, the application incorporation of
126288 application code to test the circumstances of a trace event and call the trace point only if needed
126289 is usually straightforward.

126290 For performance reasons, the *posix_trace_event*( ) function should be implemented using a macro,
126291 so if the trace is inactive, the trace event point calls are latent code and must cost no more than a
126292 scalar test.

126293 The API proposed in POSIX.1-2017 does not include any triggering functionality.

126294 *B.2.11.9 Rationale on Timestamp Clock*

126295 It has been suggested that the tracing mechanism should include the possibility of specifying the
126296 clock to be used in timestamping the trace events. When application trace events must be
126297 correlated to remote trace events, such a facility could provide a global time reference not
126298 available from a local clock. Further, the application may be driven by timers based on a clock
126299 different from that used for the timestamp, and the correlation of the trace to those untraced
126300 timer activities could be an important part of the analysis of the application.

126301 However, the tracing mechanism needs to be fast and just the provision of such an option can
126302 materially affect its performance. Leaving aside the performance costs of reading some clocks,
126303 this notion is also ill-defined when kernel trace events are to be traced by two applications
126304 making use of different tracing clocks. This can even happen within a single application where
126305 different parts of the application are served by different clocks. Another complication can occur
126306 when a clock is maintained strictly at the user level and is unavailable at the kernel level.

126307 It is felt that the benefits of a selectable trace clock do not match its costs. Applications that wish
126308 to correlate clocks other than the default tracing clock can include trace events with sample
126309 values of those other clocks, allowing correlation of timestamps from the various independent
126310 clocks. In any case, such a technique would be required when applications are sensitive to

126311 multiple clocks.

126312 *B.2.11.10 Rationale on Different Overrun Conditions*

126313 The analysis of the dynamic behavior of the trace mechanism shows that different overrun
126314 conditions may occur. The API must provide a means to manage such conditions in a portable
126315 way.

126316 **Overrun in Trace Streams Initialized with POSIX_TRACE_LOOP Policy**

126317 In this case, the user of the trace mechanism is interested in using the trace stream with
126318 POSIX_TRACE_LOOP policy to record trace events continuously, but ideally without losing any
126319 trace events. The online analyzer process must get the trace events at a mean speed equivalent to
126320 the recording speed. Should the trace stream become full, a trace stream overrun occurs. This
126321 condition is detected by getting the status of the active trace stream (function
126322 *posix_trace_get_status*()) and looking at the member *posix_stream_overrun_status* of the read
126323 **posix_stream_status** structure. In addition, two predefined trace event types are defined:

126324 1. The beginning of a trace overflow, to locate the beginning of an overflow when reading a
126325 trace stream

126326 2. The end of a trace overflow, to locate the end of an overflow, when reading a trace stream

126327 As a timestamp is associated with these predefined trace events, it is possible to know the
126328 duration of the overflow.

126329 **Overrun in Dumping Trace Streams into Trace Logs**

126330 The user lets the trace mechanism dump the trace stream initialized with
126331 POSIX_TRACE_FLUSH policy automatically into a trace log. If the dump operation is slower
126332 than the recording of trace events, the trace stream can overrun. This condition is detected by
126333 getting the status of the active trace stream (the *posix_trace_get_status*() function) and looking at
126334 the member *posix_stream_overrun_status* of the read **posix_stream_status** structure. This overrun
126335 indicates that the trace mechanism is not able to operate in this mode at this speed. It is the
126336 responsibility of the user to modify one of the trace parameters (the stream size or the trace
126337 event type filter, for instance) to avoid such overrun conditions, if overruns are to be prevented.
126338 The same already predefined trace event types (see Overrun in Trace Streams Initialized with
126339 POSIX_TRACE_LOOP Policy) are used to detect and to know the duration of an overflow.

126340 **Reading an Active Trace Stream**

126341 Although this trace API allows one to read an active trace stream with log while it is tracing, this
126342 feature can lead to false overflow origin interpretation: the trace log or the reader of the trace
126343 stream. Reading from an active trace stream with log is thus non-portable, and has been left
126344 unspecified.

B.2.12 Data Types

B.2.12.1 Defined Types

The requirement that additional types defined in this section end in ``_t'' was prompted by the problem of name space pollution. It is difficult to define a type (where that type is not one defined by POSIX.1-2017) in one header file and use it in another without adding symbols to the name space of the program. To allow implementors to provide their own types, all conforming applications are required to avoid symbols ending in ``_t'', which permits the implementor to provide additional types. Because a major use of types is in the definition of structure members, which can (and in many cases must) be added to the structures defined in POSIX.1-2017, the need for additional types is compelling.

The types, such as **ushort** and **ulong**, which are in common usage, are not defined in POSIX.1-2017 (although **ushort_t** would be permitted as an extension). They can be added to **<sys/types.h>** using a feature test macro (see Section B.2.2.1, on page 3566). A suggested symbol for these is _SYSIII. Similarly, the types like **u_short** would probably be best controlled by _BSD.

Some of these symbols may appear in other headers; see Section B.2.2.2 (on page 3567).

dev_t This type may be made large enough to accommodate host-locality considerations of networked systems.

This type must be arithmetic. Earlier proposals allowed this to be non-arithmetic (such as a structure) and provided a *samefile*( ) function for comparison.

gid_t Some implementations had separated **gid_t** from **uid_t** before POSIX.1 was completed. It would be difficult for them to coalesce them when it was unnecessary. Additionally, it is quite possible that user IDs might be different from group IDs because the user ID might wish to span a heterogeneous network, where the group ID might not.

For current implementations, the cost of having a separate **gid_t** will be only lexical.

mode_t This type was chosen so that implementations could choose the appropriate integer type, and for compatibility with the ISO C standard. 4.3 BSD uses **unsigned short** and the SVID uses **ushort**, which is the same. Historically, only the low-order sixteen bits are significant.

nlink_t This type was introduced in place of **short** for *st_nlink* (see the **<sys/stat.h>** header) in response to an objection that **short** was too small.

off_t This type is used to represent a file offset or file size. On systems supporting large files, **off_t** is larger than 32 bits in at least one programming environment. Other programming environments may use different sizes for **off_t**, for compatibility or other reasons.

pid_t The inclusion of this symbol was controversial because it is tied to the issue of the representation of a process ID as a number. From the point of view of a conforming application, process IDs should be ``magic cookies''[8] that are produced by calls such as *fork*( ), used by calls such as *waitpid*( ) or *kill*( ), and not otherwise

8. An historical term meaning: ``An opaque object, or token, of determinate size, whose significance is known only to the entity which created it. An entity receiving such a token from the generating entity may only make such use of the `cookie' as is defined and permitted by the supplying entity.''

126388 analyzed (except that the sign is used as a flag for certain operations).

126389 The concept of a {PID_MAX} value interacted with this in early proposals. Treating
126390 process IDs as an opaque type both removes the requirement for {PID_MAX} and
126391 allows systems to be more flexible in providing process IDs that span a large range
126392 of values, or a small one.

126393 Since the values in **uid_t**, **gid_t**, and **pid_t** will be numbers generally, and
126394 potentially both large in magnitude and sparse, applications that are based on
126395 arrays of objects of this type are unlikely to be fully portable in any case. Solutions
126396 that treat them as magic cookies will be portable.

126397 {CHILD_MAX} precludes the possibility of a ``toy implementation'', where there
126398 would only be one process.

126399 **ssize_t** This is intended to be a signed analog of **size_t**. The wording is such that an
126400 implementation may either choose to use a longer type or simply to use the signed
126401 version of the type that underlies **size_t**. All functions that return **ssize_t** (*read*()
126402 and *write*()) describe as ``implementation-defined'' the result of an input exceeding
126403 {SSIZE_MAX}. It is recognized that some implementations might have **int**s that
126404 are smaller than **size_t**. A conforming application would be constrained not to
126405 perform I/O in pieces larger than {SSIZE_MAX}, but a conforming application
126406 using extensions would be able to use the full range if the implementation
126407 provided an extended range, while still having a single type-compatible interface.

126408 The symbols **size_t** and **ssize_t** are also required in **<unistd.h>** to minimize the
126409 changes needed for calls to *read*() and *write*(). Implementors are reminded that it
126410 must be possible to include both **<sys/types.h>** and **<unistd.h>** in the same
126411 program (in either order) without error.

126412 **uid_t** Before the addition of this type, the data types used to represent these values
126413 varied throughout early proposals. The **<sys/stat.h>** header defined these values
126414 as type **short**, the **<passwd.h>** file (now **<pwd.h>** and **<grp.h>**) used an **int**, and
126415 *getuid*() returned an **int**. In response to a strong objection to the inconsistent
126416 definitions, all the types were switched to **uid_t**.

126417 In practice, those historical implementations that use varying types of this sort can
126418 typedef **uid_t** to **short** with no serious consequences.

126419 The problem associated with this change concerns object compatibility after
126420 structure size changes. Since most implementations will define **uid_t** as a short, the
126421 only substantive change will be a reduction in the size of the **passwd** structure.
126422 Consequently, implementations with an overriding concern for object
126423 compatibility can pad the structure back to its current size. For that reason, this
126424 problem was not considered critical enough to warrant the addition of a separate
126425 type to POSIX.1.

126426 The types **uid_t** and **gid_t** are magic cookies. There is no {UID_MAX} defined by
126427 POSIX.1, and no structure imposed on **uid_t** and **gid_t** other than that they be
126428 positive arithmetic types. (In fact, they could be **unsigned char**.) There is no
126429 maximum or minimum specified for the number of distinct user or group IDs.

126430 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0030 [733] is applied.

126431 *B.2.12.2 The char Type*

126432 POSIX.1-2017 explicitly requires that a **char** type is exactly one byte (8 bits).

126433 B.2.13 Status Information

126434 POSIX.1-2017 does not require all matching WNOWAIT threads (threads in a matching call to
126435 *waitid*() with the WNOWAIT flag set) to obtain a child's status information because the status
126436 information might be discarded (consumed or replaced) before one of the matching WNOWAIT
126437 threads is scheduled. If the status information is not discarded, it will remain available, so all of
126438 the matching WNOWAIT threads will (eventually) obtain the status information.

126439 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0031 [690] is applied.

126440 B.2.14 File Descriptor Allocation

126441 Functions such as *pipe*() and *socketpair*() which allocate two file descriptors are permitted to
126442 perform the two allocations independently. This means that other threads or signal handlers
126443 may perform operations on file descriptors in between the two allocations and this can result in
126444 the two file descriptors not having adjacent values or in the second allocation producing a lower
126445 value than the first.

126446 POSIX.1-2008, Technical Corrigendum 2, XSH/TC2-2008/0032 [835] is applied.

126447 B.3 System Interfaces

126448 See the RATIONALE sections on the individual reference pages.

126449 B.3.1 System Interfaces Removed in this Version

126450 The following section contains a list of the interfaces removed in POSIX.1-2017, together with
126451 advice for application developers on the alternative interfaces that should be used for maximum
126452 portability.

126453 *B.3.1.1 bcmp( )*

126454 Applications are recommended to use the *memcmp*() function instead of this function.

126455 For maximum portability, it is recommended to replace the function call to *bcmp*() as follows:

126456
```
#define bcmp(b1,b2,len) memcmp((b1), (b2), (size_t)(len))
```

126457 *B.3.1.2 bcopy( )*

126458 Applications are recommended to use the *memmove*() function instead of this function.

126459 The following are approximately equivalent (note the order of the arguments):

126460
```
bcopy(s1,s2,n) ≈ memmove(s2,s1,n)
```

126461 For maximum portability, it is recommended to replace the function call to *bcopy*() as follows:

126462
```
#define bcopy(b1,b2,len) (void)(memmove((b2), (b1), (len)))
```

126463 *B.3.1.3 bsd_signal( )*

126464 Applications are recommended to use the *sigaction*( ) function instead of this function.

126465 The *bsd_signal*( ) function was supplied as a migration path for the BSD *signal*( ) function for
126466 simple applications that installed a single-argument signal handler function.

126467 Historically, the *bsd_signal*( ) function differs from *signal*( ) in that the SA_RESTART flag is set
126468 and the SA_RESETHAND flag is clear when *bsd_signal*( ) is used. The state of these flags is not
126469 specified for *signal*( ).

126470 *B.3.1.4 bzero( )*

126471 Applications are recommended to use the *memset*( ) function instead of this function.

126472 For maximum portability, it is recommended to replace the function call to *bzero*( ) as follows:

126473
```
#define bzero(b,len) (void)(memset((b), '\0', (len)))
```

126474 *B.3.1.5 ecvt( ), fcvt( ), gcvt( )*

126475 Applications are recommended to use the *sprintf*( ) function instead of these functions.

126476 The *sprintf*( ) function is required by ISO C and is thus more portable.

126477 *B.3.1.6 ftime( )*

126478 Applications are recommended to use the *time*( ) function to determine the current time.
126479 Realtime applications should use *clock_gettime*( ) to determine the current time.

126480 *B.3.1.7 getcontext( ), makecontext( ), swapcontext( )*

126481 Due to portability issues with these functions, especially with the manipulation of contexts,
126482 applications are recommended to be rewritten to use POSIX threads.

126483 *B.3.1.8 gethostbyaddr( ), gethostbyname( )*

126484 Applications are recommended to use the *getaddrinfo*( ) and *getnameinfo*( ) functions instead of
126485 these functions.

126486 The *gethostbyaddr*( ) and *gethostbyname*( ) functions may return pointers to static data, which may
126487 be overwritten by subsequent calls to any of these functions. The suggested replacements do not
126488 have this problem and are also IPv6-capable.

126489 *B.3.1.9 getwd( )*

126490 Applications are recommended to use the *getcwd*( ) function to determine the current working
126491 directory.

126492 *B.3.1.10 h_errno*

126493 Applications are recommended not to use this error return code. Previously it was set by the
126494 *gethostbyaddr*( ) and *gethostbyname*( ) functions.

126495 *B.3.1.11 index( )*

126496 Applications are recommended to use the *strchr*( ) function instead of this function.

126497 For maximum portability, it is recommended to replace the function call to *index*( ) as follows:

126498
```
#define index(a,b) strchr((a),(b))
```

126499 *B.3.1.12 makecontext( )*

126500 Applications using the *getcontext*( ), *makecontext*( ), and *swapcontext*( ) functions should be
126501 rewritten to use POSIX threads.

126502 *B.3.1.13 mktemp( )*

126503 Applications are recommended to use the *mkstemp*( ) function instead of this function.

126504 The *mktemp*( ) function makes an application vulnerable to possible security problems since
126505 between the time a pathname is created and the file opened, it is possible for some other process
126506 to create a file with the same name. The *mkstemp*( ) function does not have this vulnerability.

126507 *B.3.1.14 pthread_attr_getstackaddr( ), pthread_attr_setstackaddr( )*

126508 Applications are recommended to use the *pthread_attr_setstack*( ) and *pthread_attr_getstack*( )
126509 functions instead of these functions.

126510 There are a number of ambiguities in the specification of the *stackaddr* attribute that makes
126511 portable use of these interfaces impossible.

126512 *B.3.1.15 rindex( )*

126513 Applications are recommended to use the *strrchr*( ) function instead of this function.

126514 For maximum portability, it is recommended to replace the function call to *rindex*( ) as follows:

126515
```
#define rindex(a,b) strrchr((a),(b))
```

126516 *B.3.1.16 scalb( )*

126517 Applications are recommended to use either *scalbln*( ), *scalblnf*( ), or *scalblnl*( ) instead of these
126518 functions.

126519 The behavior for the *scalb*( ) function was only defined when the *n* argument is an integer, a
126520 NaN, or Inf. The behavior of other values for the *n* argument was unspecified.

126521 *B.3.1.17 ualarm( )*

126522 Applications are recommended to use *timer_create*( ), *timer_delete*( ), *timer_getoverrun*( ),
126523 *timer_gettime*( ), or *timer_settime*( ) instead of this function.

126524 *B.3.1.18 usleep( )*

126525 Applications are recommended to use the *nanosleep*( ) function instead of this function.

126526 *B.3.1.19 vfork( )*

126527 Applications are recommended to use the *fork*( ) function instead of this function.

126528 The *vfork*( ) function was previously under-specified.

126529 *B.3.1.20 wcswcs( )*

126530 Applications are recommended to use the *wcsstr*( ) function instead of this function.

126531 The *wcsstr*( ) function is technically equivalent and is portable across all ISO C implementations.

126532 ## B.3.2 System Interfaces Removed in the Previous Version

126533 The following system interfaces, headers, and external variables were removed in the previous
126534 version of this standard:

126535 *advance*( )	*getdtablesize*( )	*re_exec*( )	*ttyslot*( )	*loc1*
126536 *brk*( )	*getpagesize*( )	*regcmp*( )	*valloc*( )	**__loc1**
126537 *chroot*( )	*getpass*( )	*regex*( )	*wait3*( )	*loc2*
126538 *compile*( )	*getw*( )	*sbrk*( )	**<re_comp.h>**	*locs*
126539 *cuserid*( )	*putw*( )	*sigstack*( )	**<regexp.h>**	
126540 *gamma*( )	*re_comp*( )	*step*( )	**<varargs.h>**	

126541 ## B.3.3 Examples for Spawn

126542 The following long examples are provided in the Rationale (Informative) volume of
126543 POSIX.1-2017 as a supplement to the reference page for *posix_spawn*( ).

126544 **Example Library Implementation of Spawn**

126545 The *posix_spawn*( ) or *posix_spawnp*( ) functions provide the following:

126546 Simply start a process executing a process image. This is the simplest application for
126547 process creation, and it may cover most executions of *fork*( ).

126548 Support I/O redirection, including pipes.

126549 Run the child under a user and group ID in the domain of the parent.

126550 Run the child at any priority in the domain of the parent.

126551 The *posix_spawn*( ) or *posix_spawnp*( ) functions do not cover every possible use of the *fork*( )
126552 function, but they do span the common applications: typical use by a shell and a login utility.

126553 The price for an application is that before it calls *posix_spawn*( ) or *posix_spawnp*( ), the parent
126554 must adjust to a state that *posix_spawn*( ) or *posix_spawnp*( ) can map to the desired state for the

child. Environment changes require the parent to save some of its state and restore it afterwards. The effective behavior of a successful invocation of *posix_spawn*() is as if the operation were implemented with POSIX operations as follows:

```
#include <sys/types.h>
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <sched.h>
#include <fcntl.h>
#include <signal.h>
#include <errno.h>
#include <string.h>
#include <signal.h>

/* #include <spawn.h> */
/****************************************/
/* Things that could be defined in spawn.h */
/****************************************/

126656              /* Worry about thread signal mask */
126657              if (attrp->posix_attr_flags & POSIX_SPAWN_SETSIGMASK)
```

```
126658                  {
126659                      /* Set the signal mask (cannot fail) */
126660                      sigprocmask(SIG_SETMASK, &attrp->posix_attr_sigmask, NULL);
126661                  }
126662                  /* Worry about resetting effective user and group IDs */
126663                  if (attrp->posix_attr_flags & POSIX_SPAWN_RESETIDS)
126664                  {
126665                      /* None of these can fail for this case. */
126666                      setuid(getuid());
126667                      setgid(getgid());
126668                  }
126669                  /* Worry about defaulted signals */
126670                  if (attrp->posix_attr_flags & POSIX_SPAWN_SETSIGDEF)
126671                  {
126672                      struct sigaction deflt;
126673                      sigset_t all_signals;
126674                      int s;
126675                      /* Construct default signal action */
126676                      deflt.sa_handler = SIG_DFL;
126677                      deflt.sa_flags = 0;
126678                      /* Construct the set of all signals */
126679                      sigfillset(&all_signals);
126680                      /* Loop for all signals */
126681                      for (s = 0; sigismember(&all_signals, s); s++)
126682                      {
126683                          /* Signal to be defaulted? */
126684                          if (sigismember(&attrp->posix_attr_sigdefault, s))
126685                          {
126686                              /* Yes; default this signal */
126687                              if (sigaction(s, &deflt, NULL) == -1)
126688                              {
126689                                  /* Failed */
126690                                  exit(127);
126691                              }
126692                          }
126693                      }
126694                  }
126695                  /* Worry about the fds if they are to be mapped */
126696                  if (file_actions != NULL)
126697                  {
126698                      /* Loop for all actions in object file_actions */
126699                      /* (implementation dives beneath abstraction) */
126700                      char *p = *file_actions;
126701                      while (*p != '\0')
126702                      {
126703                          if (strncmp(p, "close(", 6) == 0)
126704                          {
126705                              int fd;
```

```
126706                  if (sscanf(p + 6, "%d)", &fd) != 1)
126707                  {
126708                      exit(127);
126709                  }
126710                  if (close(fd) == -1)
126711                      exit(127);
126712              }
126713              else if (strncmp(p, "dup2(", 5) == 0)
126714              {
126715                  int fd, newfd;
126716                  if (sscanf(p + 5, "%d,%d)", &fd, &newfd) != 2)
126717                  {
126718                      exit(127);
126719                  }
126720                  if (dup2(fd, newfd) == -1)
126721                      exit(127);
126722              }
126723              else if (strncmp(p, "open(", 5) == 0)
126724              {
126725                  int fd, oflag;
126726                  mode_t mode;
126727                  int tempfd;
126728                  char path[1000];    /* Should be dynamic */
126729                  char *q;
126730                  if (sscanf(p + 5, "%d,", &fd) != 1)
126731                  {

126950      int posix_spawnattr_setsigdefault(posix_spawnattr_t *attr,
126951          const sigset_t *sigdefault)
126952      {
126953          attr->posix_attr_sigdefault = *sigdefault;
126954          return 0;
126955      }
```

126956 **I/O Redirection with Spawn**

126957 I/O redirection with *posix_spawn*() or *posix_spawnp*() is accomplished by crafting a *file_actions*
126958 argument to effect the desired redirection. Such a redirection follows the general outline of the
126959 following example:

```
126960 /* To redirect new standard output (fd 1) to a file, */
126961 /* and redirect new standard input (fd 0) from my fd socket_pair[1], */
126962 /* and close my fd socket_pair[0] in the new process. */
126963 posix_spawn_file_actions_t file_actions;
126964 posix_spawn_file_actions_init(&file_actions);
126965 posix_spawn_file_actions_addopen(&file_actions, 1, "newout", ...);
126966 posix_spawn_file_actions_dup2(&file_actions, socket_pair[1], 0);
126967 posix_spawn_file_actions_close(&file_actions, socket_pair[0]);
126968 posix_spawn_file_actions_close(&file_actions, socket_pair[1]);
126969 posix_spawn(..., &file_actions, ...);
126970 posix_spawn_file_actions_destroy(&file_actions);
```

126971 **Spawning a Process Under a New User ID**

126972 Spawning a process under a new user ID follows the outline shown in the following example:

```
126973 Save = getuid();
126974 setuid(newid);
126975 posix_spawn(...);
126976 setuid(Save);
```

Shell and Utilities

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

126982 *Appendix C*

126983 # *Rationale for Shell and Utilities*

126984 ## C.1 Introduction

126985 ### C.1.1 Change History

126986 The change history is provided as an informative section, to track changes from earlier versions
126987 of this standard.

126988 The following sections describe changes made to the Shell and Utilities volume of POSIX.1-2017
126989 since Issue 6 of the base document. The CHANGE HISTORY section for each utility describes
126990 technical changes made to that utility from Issue 5. Changes between earlier versions of the base
126991 document and Issue 5 are not included.

126992 **Changes from Issue 6 to Issue 7 (POSIX.1-2008)**

126993 The following list summarizes the major changes that were made in the Shell and Utilities
126994 volume of POSIX.1-2017 from Issue 6 to Issue 7:

126995 Austin Group defect reports, IEEE Interpretations against IEEE Std 1003.1, and responses
126996 to ISO/IEC defect reports against ISO/IEC 9945 are applied.

126997 The Open Group corrigenda and resolutions are applied.

126998 Features, marked legacy or obsolescent in the base document, have been considered for
126999 removal in this version.

127000 A review of the use of fixed pathnames within the standard has been undertaken; for
127001 example, the *at*, *batch*, and *crontab* utilities previously had a requirement for use of the
127002 directory **/usr/lib/cron**.

127003 The options within the standard have been revised.

127004 ‡ĸéĪBatch Environment Services and Utilities option is marked obsolescent.

127005 ‡ĸéĪUUCP utilities option is added.

127006 ‡ĸéĪUser Portability Utilities option is revised so that only the *bg*, *ex*, *fc*, *fg*, *jobs*, *more*,
127007 *talk*, and *vi* utilities are included, the rest being moved to the Base.

New Features in Issue 7

There are no new utilities in Issue 7.

C.1.2 Relationship to Other Documents

C.1.2.1 System Interfaces

It has been pointed out that the Shell and Utilities volume of POSIX.1-2017 assumes that a great deal of functionality from the System Interfaces volume of POSIX.1-2017 is present, but never states exactly how much (and strictly does not need to since both are mandated on a conforming system). This section is an attempt to clarify the assumptions.

File Read, Write, and Creation

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/2 is applied, updating Table 1-1.

File Removal

This is intended to be a summary of the *unlink*() and *rmdir*() requirements. Note that it is possible using the *unlink*() function for item 4. to occur.

C.1.2.2 Concepts Derived from the ISO C Standard

This section was introduced to address the issue that there was insufficient detail presented by such utilities as *awk* or *sh* about their procedural control statements and their methods of performing arithmetic functions.

The ISO C standard was selected as a model because most historical implementations of the standard utilities were written in C. Thus, it was more likely that they would act in the desired manner without modification.

Using the ISO C standard is primarily a notational convenience so that the many procedural languages in the Shell and Utilities volume of POSIX.1-2017 would not have to be rigorously described in every aspect. Its selection does not require that the standard utilities be written in Standard C; they could be written in Common Usage C, Ada, Pascal, assembler language, or anything else.

The sizes of the various numeric values refer to C-language data types that are allowed to be different sizes by the ISO C standard. Thus, like a C-language application, a shell application cannot rely on their exact size. However, it can rely on their minimum sizes expressed in the ISO C standard, such as {LONG_MAX} for a **long** type.

The behavior on overflow is undefined for ISO C standard arithmetic. Therefore, the standard utilities can use ``bignum'' representation for integers so that there is no fixed maximum unless otherwise stated in the utility description. Similarly, standard utilities can use infinite-precision representations for floating-point arithmetic, as long as these representations exceed the ISO C standard requirements.

This section addresses only the issue of semantics; it is not intended to specify syntax. For example, the ISO C standard requires that 0L be recognized as an integer constant equal to zero, but utilities such as *awk* and *sh* are not required to recognize 0L (though they are allowed to, as an extension).

The ISO C standard requires that a C compiler must issue a diagnostic for constants that are too large to represent. Most standard utilities are not required to issue these diagnostics; for example, the command:

```
diff -C 2147483648 file1 file2
```

has undefined behavior, and the *diff* utility is not required to issue a diagnostic even if the number 2 147 483 648 cannot be represented.

C.1.3 Utility Limits

This section grew out of an idea that originated with the original POSIX.1, in the tables of system limits for the *sysconf*( ) and *pathconf*( ) functions. The idea being that a conforming application can be written to use the most restrictive values that a minimal system can provide, but it should not have to. The values provided represent compromises so that some vendors can use historically limited versions of UNIX system utilities. They are the highest values that a strictly conforming application can assume, given no other information.

However, by using the *getconf* utility or the *sysconf*( ) function, the elegant application can be tailored to more liberal values on some of the specific instances of specific implementations.

There is no explicitly stated requirement that an implementation provide finite limits for any of these numeric values; the implementation is free to provide essentially unbounded capabilities (where it makes sense), stopping only at reasonable points such as {ULONG_MAX} (from the ISO C standard). Therefore, applications desiring to tailor themselves to the values on a particular implementation need to be ready for possibly huge values; it may not be a good idea to allocate blindly a buffer for an input line based on the value of {LINE_MAX}, for instance. However, unlike the System Interfaces volume of POSIX.1-2017, there is no set of limits that return a special indication meaning ``unbounded''. The implementation should always return an actual number, even if the number is very large.

The statement:

> ``It is not guaranteed that the application ...''

is an indication that many of these limits are designed to ensure that implementors design their utilities without arbitrary constraints related to unimaginative programming. There are certainly conditions under which combinations of options can cause failures that would not render an implementation non-conforming. For example, {EXPR_NEST_MAX} and {ARG_MAX} could collide when expressions are large; combinations of {BC_SCALE_MAX} and {BC_DIM_MAX} could exceed virtual memory.

In the Shell and Utilities volume of POSIX.1-2017, the notion of a limit being guaranteed for the process lifetime, as it is in the System Interfaces volume of POSIX.1-2017, is not as useful to a shell script. The *getconf* utility is probably a process itself, so the guarantee would be without value. Therefore, the Shell and Utilities volume of POSIX.1-2017 requires the guarantee to be for the session lifetime. This will mean that many vendors will either return very conservative values or possibly implement *getconf* as a built-in.

It may seem confusing to have limits that apply only to a single utility grouped into one global section. However, the alternative, which would be to disperse them out into their utility description sections, would cause great difficulty when *sysconf*( ) and *getconf* were described. Therefore, the standard developers chose the global approach.

Each language binding could provide symbol names that are slightly different from those shown here. For example, the C-Language Binding option adds a leading <underscore> to the symbols as a prefix.

The following comments describe selection criteria for the symbols and their values:

{ARG_MAX}
This is defined by the System Interfaces volume of POSIX.1-2017. Unfortunately, it is very difficult for a conforming application to deal with this value, as it does not know how much of its argument space is being consumed by the environment variables of the user.

{BC_BASE_MAX}
{BC_DIM_MAX}
{BC_SCALE_MAX}
These were originally one value, {BC_SCALE_MAX}, but it was unreasonable to link all three concepts into one limit.

{CHILD_MAX}
This is defined by the System Interfaces volume of POSIX.1-2017.

{COLL_WEIGHTS_MAX}
The weights assigned to **order** can be considered as ``passes'' through the collation algorithm.

{EXPR_NEST_MAX}
The value for expression nesting was borrowed from the ISO C standard.

{LINE_MAX}
This is a global limit that affects all utilities, unless otherwise noted. The {MAX_CANON} value from the System Interfaces volume of POSIX.1-2017 may further limit input lines from terminals. The {LINE_MAX} value was the subject of much debate and is a compromise between those who wished to have unlimited lines and those who understood that many historical utilities were written with fixed buffers. Frequently, utility writers selected the UNIX system constant BUFSIZ to allocate these buffers; therefore, some utilities were limited to 512 bytes for I/O lines, while others achieved 4 096 bytes or greater.

It should be noted that {LINE_MAX} applies only to input line length; there is no requirement in POSIX.1-2017 that limits the length of output lines. Utilities such as *awk*, *sed*, and *paste* could theoretically construct lines longer than any of the input lines they received, depending on the options used or the instructions from the application. They are not required to truncate their output to {LINE_MAX}. It is the responsibility of the application to deal with this. If the output of one of those utilities is to be piped into another of the standard utilities, line length restrictions will have to be considered; the *fold* utility, among others, could be used to ensure that only reasonable line lengths reach utilities or applications.

{LINK_MAX}
This is defined by the System Interfaces volume of POSIX.1-2017.

{MAX_CANON}
{MAX_INPUT}
{NAME_MAX}
{NGROUPS_MAX}
{OPEN_MAX}
{PATH_MAX}
{PIPE_BUF}
These limits are defined by the System Interfaces volume of POSIX.1-2017. Note that the byte lengths described by some of these values continue to represent bytes, even if the applicable character set uses a multi-byte encoding.

{RE_DUP_MAX}

The value selected is consistent with historical practice. Although the name implies that it applies to all REs, only BREs use the interval notation \{*m*,*n*\} addressed by this limit.

{POSIX2_SYMLINKS}

The {POSIX2_SYMLINKS} variable indicates that the underlying operating system supports the creation of symbolic links in specific directories. Many of the utilities defined in POSIX.1-2017 that deal with symbolic links do not depend on this value. For example, a utility that follows symbolic links (or does not, as the case may be) will only be affected by a symbolic link if it encounters one. Presumably, a file system that does not support symbolic links will not contain any. This variable does affect such utilities as *ln* **−s** and *pax* that attempt to create symbolic links.

There are different limits associated with command lines and input to utilities, depending on the method of invocation. In the case of a C program *exec*-ing a utility, {ARG_MAX} is the underlying limit. In the case of the shell reading a script and *exec*-ing a utility, {LINE_MAX} limits the length of lines the shell is required to process, and {ARG_MAX} will still be a limit. If a user is entering a command on a terminal to the shell, requesting that it invoke the utility, {MAX_INPUT} may restrict the length of the line that can be given to the shell to a value below {LINE_MAX}.

When an option is supported, *getconf* returns a value of 1. For example, when C development is supported:

```
if [ "$(getconf POSIX2_C_DEV)" −eq 1 ]; then
    echo C supported
fi
```

The *sysconf*( ) function in the C-Language Binding option would return 1.

The following comments describe selection criteria for the symbols and their values:

POSIX2_C_BIND
POSIX2_C_DEV
POSIX2_FORT_DEV
POSIX2_FORT_RUN
POSIX2_SW_DEV
POSIX2_UPE

It is possible for some (usually privileged) operations to remove utilities that support these options or otherwise to render these options unsupported. The header files, the *sysconf*( ) function, or the *getconf* utility will not necessarily detect such actions, in which case they should not be considered as rendering the implementation non-conforming. A test suite should not attempt tests such as:

```
rm /usr/bin/c99
getconf POSIX2_C_DEV
```

POSIX2_LOCALEDEF

This symbol was introduced to allow implementations to restrict supported locales to only those supplied by the implementation.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/2 is applied, deleting the entry for {POSIX2_VERSION} since it is not a utility limit minimum value.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/3 is applied, changing the text in Utility Limits from: ``utility (see *getconf*) through the *sysconf*( ) function defined in the System Interfaces volume of POSIX.1-2017. The literal names shown in Table 1-3 apply only to the *getconf* utility; the high-level language binding describes the exact form of each name to be used by the

127184 interfaces in that binding.'' to: ``utility (see *getconf*).''.

127185 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0001 [666] is applied.

127186 C.1.4 Grammar Conventions

127187 There is no additional rationale provided for this section.

127188 C.1.5 Utility Description Defaults

127189 This section is arranged with headings in the same order as all the utility descriptions. It is a
127190 collection of related and unrelated information concerning:

127191 1. The default actions of utilities

127192 2. The meanings of notations used in POSIX.1-2017 that are specific to individual utility
127193 sections

127194 Although this material may seem out of place here, it is important that this information appear
127195 before any of the utilities to be described later.

127196 **NAME**

127197 There is no additional rationale provided for this section.

127198 **SYNOPSIS**

127199 There is no additional rationale provided for this section.

127200 **DESCRIPTION**

127201 There is no additional rationale provided for this section.

127202 **OPTIONS**

127203 Although it has not always been possible, the standard developers tried to avoid repeating
127204 information to reduce the risk that duplicate explanations could each be modified differently.

127205 The need to recognize `--` is required because conforming applications need to shield their
127206 operands from any arbitrary options that the implementation may provide as an extension. For
127207 example, if the standard utility *foo* is listed as taking no options, and the application needed to
127208 give it a pathname with a leading <hyphen-minus>, it could safely do it as:

127209 `foo -- -myfile`

127210 and avoid any problems with **–m** used as an extension.

127211 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0002 [584] is applied.

127212 **OPERANDS**

127213 The usage of – is never shown in the SYNOPSIS. Similarly, the usage of –– is never shown.

127214 The requirement for processing operands in command-line order is to avoid a ``WeirdNIX'' utility that might choose to sort the input files alphabetically, by size, or by directory order.
127215 Although this might be acceptable for some utilities, in general the programmer has a right to
127216 know exactly what order will be chosen.
127217

127218 Some of the standard utilities take multiple *file* operands and act as if they were processing the
127219 concatenation of those files. For example:

127220 `asa file1 file2`
127221 and:

127222 `cat file1 file2 | asa`

127223 have similar results when questions of file access, errors, and performance are ignored. Other
127224 utilities such as *grep* or *wc* have completely different results in these two cases. This latter type of
127225 utility is always identified in its DESCRIPTION or OPERANDS sections, whereas the former is
127226 not. Although it might be possible to create a general assertion about the former case, the
127227 following points must be addressed:

127228 Access times for the files might be different in the operand case *versus* the *cat* case.

127229 The utility may have error messages that are cognizant of the input filename, and this
127230 added value should not be suppressed. (As an example, *awk* sets a variable with the
127231 filename at each file boundary.)

127232 **STDIN**

127233 There is no additional rationale provided for this section.

127234 **INPUT FILES**

127235 A conforming application cannot assume the following three commands are equivalent:

```
127236 tail −n +2 file
127237 (sed −n 1q; cat) < file
127238 cat file | (sed −n 1q; cat)
```

127239 The second command is equivalent to the first only when the file is seekable. In the third
127240 command, if the file offset in the open file description were not unspecified, *sed* would have to
127241 be implemented so that it read from the pipe 1 byte at a time or it would have to employ some
127242 method to seek backwards on the pipe. Such functionality is not defined currently in POSIX.1
127243 and does not exist on all historical systems. Other utilities, such as *head*, *read*, and *sh*, have similar
127244 properties, so the restriction is described globally in this section.

127245 The definition of ``text file'' is strictly enforced for input to the standard utilities; very few of
127246 them list exceptions to the undefined results called for here. (Of course, ``undefined'' here does
127247 not mean that historical implementations necessarily have to change to start indicating error
127248 conditions. Conforming applications cannot rely on implementations succeeding or failing when
127249 non-text files are used.)

127250 The utilities that allow line continuation are generally those that accept input languages, rather
127251 than pure data. It would be unusual for an input line of this type to exceed {LINE_MAX} bytes
127252 and unreasonable to require that the implementation allow unlimited accumulation of multiple
127253 lines, each of which could reach {LINE_MAX}. Thus, for a conforming application the total of all
127254 the continued lines in a set cannot exceed {LINE_MAX}.

The format description is intended to be sufficiently rigorous to allow other applications to generate these input files. However, since <blank> characters can legitimately be included in some of the fields described by the standard utilities, particularly in locales other than the POSIX locale, this intent is not always realized.

ENVIRONMENT VARIABLES

There is no additional rationale provided for this section.

ASYNCHRONOUS EVENTS

Because there is no language prohibiting it, a utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

STDOUT

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

STDERR

This section does not describe error messages that refer to incorrect operation of the utility. Consider a utility that processes program source code as its input. This section is used to describe messages produced by a correctly operating utility that encounters an error in the program source code on which it is processing. However, a message indicating that the utility had insufficient memory in which to operate would not be described.

Some utilities have traditionally produced warning messages without returning a non-zero exit status; these are specifically noted in their sections. Other utilities shall not write to standard error if they complete successfully, unless the implementation provides some sort of extension to increase the verbosity or debugging level.

The format descriptions are intended to be sufficiently rigorous to allow post-processing of output by other programs.

OUTPUT FILES

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

EXTENDED DESCRIPTION

There is no additional rationale provided for this section.

EXIT STATUS

Note the additional discussion of exit values in *Exit Status for Commands* in the *sh* utility. It describes requirements for returning exit values greater than 125.

A utility may list zero as a successful return, 1 as a failure for a specific reason, and greater than 1 as ``an error occurred''. In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A strictly conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in POSIX.1-2017. In that way, it will have maximum portability, even on implementations with

127295 extensions.

127296 The standard developers are aware that the general non-enumeration of errors makes it difficult
127297 to write test suites that test the *incorrect* operation of utilities. There are some historical
127298 implementations that have expended effort to provide detailed status messages and a helpful
127299 environment to bypass or explain errors, such as prompting, retrying, or ignoring unimportant
127300 syntax errors; other implementations have not. Since there is no realistic way to mandate system
127301 behavior in cases of undefined application actions or system problems ‡in a manner acceptable
127302 to all cultures and environments—attention has been limited to the correct operation of utilities
127303 by the conforming application. Furthermore, the conforming application does not need detailed
127304 information concerning errors that it caused through incorrect usage or that it cannot correct.

127305 There is no description of defaults for this section because all of the standard utilities specify
127306 something (or explicitly state ``Unspecified'') for exit status.

127307 **CONSEQUENCES OF ERRORS**

127308 Several actions are possible when a utility encounters an error condition, depending on the
127309 severity of the error and the state of the utility. Included in the possible actions of various
127310 utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; and
127311 validity checking of the file system or directory.

127312 The text about recursive traversing is meant to ensure that utilities such as *find* process as many
127313 files in the hierarchy as they can. They should not abandon all of the hierarchy at the first error
127314 and resume with the next command-line operand, but should attempt to keep going.

127315 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0001 [150] is applied.

127316 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0003 [913] is applied.

127317 **APPLICATION USAGE**

127318 This section provides additional caveats, issues, and recommendations to the developer.

127319 **EXAMPLES**

127320 This section provides sample usage.

127321 **RATIONALE**

127322 There is no additional rationale provided for this section.

127323 **FUTURE DIRECTIONS**

127324 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in
127325 the future, and often cautions the developer to architect the code to account for a change in this
127326 area. Note that a future directions statement should not be taken as a commitment to adopt a
127327 feature or interface in the future.

127328 **SEE ALSO**

127329 There is no additional rationale provided for this section.

127330 **CHANGE HISTORY**

127331 There is no additional rationale provided for this section.

C.1.6 Considerations for Utilities in Support of Files of Arbitrary Size

This section is intended to clarify the requirements for utilities in support of large files.

The utilities listed in this section are utilities which are used to perform administrative tasks such as to create, move, copy, remove, change the permissions, or measure the resources of a file. They are useful both as end-user tools and as utilities invoked by applications during software installation and operation.

The *chgrp*, *chmod*, *chown*, *ln*, and *rm* utilities probably require use of large file-capable versions of *stat*( ), *lstat*( ), *ftw*( ), and the **stat** structure.

The *cat*, *cksum*, *cmp*, *cp*, *dd*, *mv*, *sum*, and *touch* utilities probably require use of large file-capable versions of *creat*( ), *open*( ), and *fopen*( ).

The *cat*, *cksum*, *cmp*, *dd*, *df*, *du*, *ls*, and *sum* utilities may require writing large integer values. For example:

The *cat* utility might have a **–n** option which counts <newline> characters.

The *cksum* and *ls* utilities report file sizes.

The *cmp* utility reports the line number at which the first difference occurs, and also has a **–l** option which reports file offsets.

The *dd*, *df*, *du*, *ls*, and *sum* utilities report block counts.

The *dd*, *find*, and *test* utilities may need to interpret command arguments that contain 64-bit values. For *dd*, the arguments include *skip=n*, *seek=n*, and *count=n*. For *find*, the arguments include **–size***n*. For *test*, the arguments are those associated with algebraic comparisons.

The *df* utility might need to access large file systems with *statvfs*( ).

The *ulimit* utility will need to use large file-capable versions of *getrlimit*( ) and *setrlimit*( ) and be able to read and write large integer values.

C.1.7 Built-In Utilities

All of these utilities can be *exec*-ed. There is no requirement that these utilities are actually built into the shell itself, but many shells need the capability to do so because XCU Section 2.9.1.1 (on page 2367) requires that they be found prior to the *PATH* search. The shell could satisfy its requirements by keeping a list of the names and directly accessing the file-system versions regardless of *PATH*. Providing all of the required functionality for those such as *cd* or *read* would be more difficult.

There were originally three justifications for allowing the omission of *exec*-able versions:

1. It would require wasting space in the file system, at the expense of very small systems. However, it has been pointed out that all 16 utilities in the table can be provided with 16 links to a single-line shell script:

   ```
   $0 "$@"
   ```

2. It is not logical to require invocation of utilities such as *cd* because they have no value outside the shell environment or cannot be useful in a child process. However, counter-examples always seemed to be available for even the most unusual cases:

   ```
   find . –type d –exec cd {} \; –exec foo {} \;
   ```

   (which invokes ``foo'' on accessible directories)

   ```
   ps ... | sed ... | xargs kill
   ```

```
find . -exec true \; -a ...
```
(where ``true'' is used for temporary debugging)

3. It is confusing to have a utility such as *kill* that can easily be in the file system in the base standard, but that requires built-in status for the User Portability Utilities option (for the `%` job control job ID notation). It was decided that it was more appropriate to describe the required functionality (rather than the implementation) to the system implementors and let them decide how to satisfy it.

On the other hand, it was realized that any distinction like this between utilities was not useful to applications, and that the cost to correct it was small. These arguments were ultimately the most effective.

There were varying reasons for including utilities in the table of built-ins:

alias, *fc*, *unalias*
: The functionality of these utilities is performed more simply within the shell itself and that is the model most historical implementations have used.

bg, *fg*, *jobs*
: All of the job control-related utilities are eligible for built-in status because that is the model most historical implementations have used.

cd, *getopts*, *newgrp*, *read*, *umask*, *wait*
: The functionality of these utilities is performed more simply within the context of the current process. An example can be taken from the usage of the *cd* utility. The purpose of the *cd* utility is to change the working directory for subsequent operations. The actions of *cd* affect the process in which *cd* is executed and all subsequent child processes of that process. Based on the POSIX standard process model, changes in the process environment of a child process have no effect on the parent process. If the *cd* utility were executed from a child process, the working directory change would be effective only in the child process. Child processes initiated subsequent to the child process that executed the *cd* utility would not have a changed working directory relative to the parent process.

command
: This utility was placed in the table primarily to protect scripts that are concerned about their *PATH* being manipulated. The ``secure'' shell script example in the *command* utility in the Shell and Utilities volume of POSIX.1-2017 would not be possible if a *PATH* change retrieved an alien version of *command*. (An alternative would have been to implement *getconf* as a built-in, but the standard developers considered that it carried too many changing configuration strings to require in the shell.)

kill Since *kill* provides optional job control functionality using shell notation (`%1`, `%2`, and so on), some implementations would find it extremely difficult to provide this outside the shell.

true, *false*
: These are in the table as a courtesy to programmers who wish to use the `"while true"` shell construct without protecting *true* from *PATH* searches. (It is acknowledged that `"while :"` also works, but the idiom with *true* is historically pervasive.)

All utilities, including those in the table, are accessible via the *system*() and *popen*() functions in the System Interfaces volume of POSIX.1-2017. There are situations where the return functionality of *system*() and *popen*() is not desirable. Applications that require the exit status of the invoked utility will not be able to use *system*() or *popen*(), since the exit status returned is that of the command language interpreter rather than that of the invoked utility. The alternative for such applications is the use of the *exec* family.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0004 [705] is applied.

C.2 Shell Command Language

C.2.1 Shell Introduction

The System V shell was selected as the starting point for the Shell and Utilities volume of POSIX.1-2017. The BSD C shell was excluded from consideration for the following reasons:

> Most historically portable shell scripts assume the Version 7 Bourne shell, from which the System V shell is derived.
>
> The majority of tutorial materials on shell programming assume the System V shell.

The construct `"#!"` is reserved for implementations wishing to provide that extension. If it were not reserved, the Shell and Utilities volume of POSIX.1-2017 would disallow it by forcing it to be a comment. As it stands, a strictly conforming application must not use `"#!"` as the first two characters of the file.

C.2.2 Quoting

There is no additional rationale provided for this section.

C.2.2.1 *Escape Character (Backslash)*

There is no additional rationale provided for this section.

C.2.2.2 *Single-Quotes*

A <backslash> cannot be used to escape a single-quote in a single-quoted string. An embedded quote can be created by writing, for example: `"'a'\''b'"`, which yields `"a'b"`. (See XCU Section 2.6.5 (on page 2359) for a better understanding of how portions of words are either split into fields or remain concatenated.) A single token can be made up of concatenated partial strings containing all three kinds of quoting or escaping, thus permitting any combination of characters.

C.2.2.3 *Double-Quotes*

The escaped <newline> used for line continuation is removed entirely from the input and is not replaced by any white space. Therefore, it cannot serve as a token separator.

In double-quoting, if a <backslash> is immediately followed by a character that would be interpreted as having a special meaning, the <backslash> is deleted and the subsequent character is taken literally. If a <backslash> does not precede a character that would have a special meaning, it is left in place unmodified and the character immediately following it is also left unmodified. Thus, for example:

```
"\$"  ->  $
"\a"  ->  \a
```

It would be desirable to include the statement ``The characters from an enclosed `"${"` to the matching `'}'` shall not be affected by the double-quotes'', similar to the one for `"$()"`. However, historical practice in the System V shell prevents this.

The requirement that double-quotes be matched inside `"${...}"` within double-quotes and the rule for finding the matching `'}'` in XCU Section 2.6.2 (on page 2354) eliminate several subtle inconsistencies in expansion for historical shells in rare cases; for example:

```
"${foo-bar"}
```

yields **bar** when **foo** is not defined, and is an invalid substitution when **foo** is defined, in many historical shells. The differences in processing the `"${...}"` form have led to inconsistencies between historical systems. A consequence of this rule is that single-quotes cannot be used to quote the `'}'` within `"${...}"`; for example:

```
unset bar
foo="${bar-'}'}"
```

is invalid because the `"${...}"` substitution contains an unpaired unescaped single-quote. The <backslash> can be used to escape the `'}'` in this example to achieve the desired result:

```
unset bar
foo="${bar-\}}"
```

The differences in processing the `"${...}"` form have led to inconsistencies between the historical System V shell, BSD, and KornShells, and the text in the Shell and Utilities volume of POSIX.1-2017 is an attempt to converge them without breaking too many applications. The only alternative to this compromise between shells would be to make the behavior unspecified whenever the literal characters single-quote, `'{'`, `'}'`, and `'"'` appear within `"${...}"`. To write a portable script that uses these values, a user would have to assign variables; for example:

```
squote=\' dquote=\" lbrace='{' rbrace='}'
${foo-$squote$rbrace$squote}
```

rather than:

```
${foo-"'}'"}
```

Some implementations have allowed the end of the word to terminate the backquoted command substitution, such as in:

```
"`echo hello"
```

This usage is undefined; the matching backquote is required by the Shell and Utilities volume of POSIX.1-2017. The other undefined usage can be illustrated by the example:

```
sh -c '` echo "foo`'
```

The description of the recursive actions involving command substitution can be illustrated with an example. Upon recognizing the introduction of command substitution, the shell parses input (in a new context), gathering the source for the command substitution until an unbalanced `')'` or `'`'` is located. For example, in the following:

```
echo "$(date; echo "
    one" )"
```

the double-quote following the *echo* does not terminate the first double-quote; it is part of the command substitution script. Similarly, in:

```
echo "$(echo *)"
```

the <asterisk> is not quoted since it is inside command substitution; however:

```
echo "$(echo "*")"
```

is quoted (and represents the <asterisk> character itself).

C.2.3 Token Recognition

The "((" and "))" symbols are control operators in the KornShell, used for an alternative syntax of an arithmetic expression command. A conforming application cannot use "((" as a single token (with the exception of the "$((" form for shell arithmetic).

On some implementations, the symbol "((" is a control operator; its use produces unspecified results. Applications that wish to have nested subshells, such as:

```
((echo Hello);(echo World))
```

must separate the "((" characters into two tokens by including white space between them. Some systems may treat these as invalid arithmetic expressions instead of subshells.

Certain combinations of characters are invalid in portable scripts, as shown in the grammar. Implementations may use these combinations (such as "|&") as valid control operators. Portable scripts cannot rely on receiving errors in all cases where this volume of POSIX.1-2017 indicates that a syntax is invalid.

The (3) rule about combining characters to form operators is not meant to preclude systems from extending the shell language when characters are combined in otherwise invalid ways. Conforming applications cannot use invalid combinations, and test suites should not penalize systems that take advantage of this fact. For example, the unquoted combination "|&" is not valid in a POSIX script, but has a specific KornShell meaning.

The (10) rule about '#' as the current character is the first in the sequence in which a new token is being assembled. The '#' starts a comment only when it is at the beginning of a token. This rule is also written to indicate that the search for the end-of-comment does not consider escaped <newline> specially, so that a comment cannot be continued to the next line.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0005 [718], XCU/TC2-2008/0006 [647], XCU/TC2-2008/0007 [568], and XCU/TC2-2008/0008 [648] are applied.

C.2.3.1 Alias Substitution

The alias capability was added because it is widely used in historical implementations by interactive users.

The definition of ``alias name'' precludes an alias name containing a <slash> character. Since the text applies to the command words of simple commands, reserved words (in their proper places) cannot be confused with aliases.

The placement of alias substitution in token recognition makes it clear that it precedes all of the word expansion steps.

An example concerning trailing <blank> characters and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

The effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of "Hello, World" strings to the screen. However, if the user types:

```
$ foo while
```

the result is an *ls* listing of **/**. Since the alias substitution for **foo** ends in a <space>, the next word is checked for alias substitution. The next word, **while**, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

```
$ foo; while
```

while retains its normal reserved-word properties.

C.2.4 Reserved Words

All reserved words are recognized syntactically as such in the contexts described. However, note that **in** is the only meaningful reserved word after a **case** or **for**; similarly, **in** is not meaningful as the first word of a simple command.

Reserved words are recognized only when they are delimited (that is, meet the definition of XBD Section 3.446, on page 105), whereas operators are themselves delimiters. For instance, `'('` and `')'` are control operators, so that no <space> is needed in (*list*). However, `'{'` and `'}'` are reserved words in { *list*;}, so that in this case the leading <space> and <semicolon> are required.

The list of unspecified reserved words is from the KornShell, so conforming applications cannot use them in places a reserved word would be recognized. This list contained **time** in early proposals, but it was removed when the *time* utility was selected for the Shell and Utilities volume of POSIX.1-2017.

There was a strong argument for promoting braces to operators (instead of reserved words), so they would be syntactically equivalent to subshell operators. Concerns about compatibility outweighed the advantages of this approach. Nevertheless, conforming applications should consider quoting `'{'` and `'}'` when they represent themselves.

The restriction on ending a name with a <colon> is to allow future implementations that support named labels for flow control; see the RATIONALE for the *break* built-in utility.

It is possible that a future version of the Shell and Utilities volume of POSIX.1-2017 may require that `'{'` and `'}'` be treated individually as control operators, although the token `"{}"` will probably be a special-case exemption from this because of the often-used *find*{} construct.

C.2.5 Parameters and Variables

C.2.5.1 *Positional Parameters*

There is no additional rationale provided for this section.

C.2.5.2 *Special Parameters*

Most historical implementations implement subshells by forking; thus, the special parameter `'$'` does not necessarily represent the process ID of the shell process executing the commands since the subshell execution environment preserves the value of `'$'`.

If a subshell were to execute a background command, the value of `"$!"` for the parent would

not change. For example:

```
(
date &
echo $!
)
echo $!
```

would echo two different values for "$!".

The "$-" special parameter can be used to save and restore *set* options:

```
Save=$(echo $- | sed 's/[ics]//g')
...
set +aCefnuvx
if [ -n "$Save" ]; then
    set -$Save
fi
```

The three options are removed using *sed* in the example because they may appear in the value of "$-" (from the *sh* command line), but are not valid options to *set*.

The descriptions of parameters '*' and '@' assume the reader is familiar with the field splitting discussion in XCU Section 2.6.5 (on page 2359) and understands that portions of the word remain concatenated unless there is some reason to split them into separate fields.

The following examples illustrate some of the ways in which '*' and '@' can be expanded:

```
set "abc" "def ghi" "jkl"
unset novar
IFS=' ' # a space
printf '%s\n' $*
abc
def
ghi
jkl
printf '%s\n' "$*"
abc def ghi jkl
printf '%s\n' xx$*yy
xxabc
def
ghi
jklyy
printf '%s\n' "xx$*yy"
xxabc def ghi jklyy
printf '%s\n' $@
abc
def
ghi
jkl
printf '%s\n' "$@"
abc
def ghi
jkl
printf '%s\n' ${1+"$@"}
abc
def ghi
```

```
127626      jkl
127627      printf '%s\n' ${novar-"$@"}
127628      abc
127629      def ghi
127630      jkl
127631      printf '%s\n' xx$@yy
127632      xxabc
127633      def
127634      ghi
127635      jklyy
127636      printf '%s\n' "xx$@yy"
127637      xxabc
127638      def ghi
127639      jklyy
127640      printf '%s\n' $@$@
127641      abc
127642      def
127643      ghi
127644      jklabc
127645      def
127646      ghi
127647      jkl
127648      printf '%s\n' "$@$@"
127649      abc
127650      def ghi
127651      jklabc
127652      def ghi
127653      jkl
127654      IFS=':'
127655      printf '%s\n' "$*"
127656      abc:def ghi:jkl
127657      var=$*; printf '%s\n' "$var"
127658      abc:def ghi:jkl
127659      var="$*"; printf '%s\n' "$var"
127660      abc:def ghi:jkl
127661      unset var
127662      printf '%s\n' ${var-$*}
127663      abc
127664      def ghi
127665      jkl
127666      printf '%s\n' "${var-$*}"
127667      abc:def ghi:jkl
127668      printf '%s\n' ${var-"$*"}
127669      abc:def ghi:jkl
127670      printf '%s\n' ${var=$*}
127671      abc
127672      def ghi
127673      jkl
127674      printf 'var=%s\n' "$var"
127675      var=abc:def ghi:jkl
127676      unset var
127677      printf '%s\n' "${var=$*}"
127678      abc:def ghi:jkl
```

```
127679      printf 'var=%s\n' "$var"
127680      var=abc:def ghi:jkl

127681      IFS='' # null
127682      printf '%s\n' "$*"
127683      abcdef ghijkl
127684      var=$*; printf '%s\n' "$var"
127685      abcdef ghijkl
127686      var="$*"; printf '%s\n' "$var"
127687      abcdef ghijkl

127692      abcdef ghijkl
127693      printf '%s\n' ${var-"$*"}
127694      abcdef ghijkl
127695      printf '%s\n' ${var=$*}
127696      abcdef ghijkl
127697      printf 'var=%s\n' "$var"
127698      var=abcdef ghijkl
127699      unset var
127700      printf '%s\n' "${var=$*}"
127701      abcdef ghijkl
127702      printf 'var=%s\n' "$var"
127703      var=abcdef ghijkl
127704      printf '%s\n' "$@"
127705      abc
127706      def ghi
127707      jkl

127708      unset IFS
127709      printf '%s\n' "$*"
127710      abc def ghi jkl
127711      var=$*; printf '%s\n' "$var"
127712      abc def ghi jkl
127713      var="$*"; printf '%s\n' "$var"
127714      abc def ghi jkl
127715      unset var
127716      printf '%s\n' ${var-$*}
127717      abc
127718      def
127719      ghi
127720      jkl
127721      printf '%s\n' "${var-$*}"
127722      abc def ghi jkl
127723      printf '%s\n' ${var-"$*"}
127724      abc def ghi jkl
127725      printf '%s\n' ${var=$*}
127726      abc
127727      def
127728      ghi
127729      jkl
127730      printf 'var=%s\n' "$var"
```

```
var=abc def ghi jkl
unset var
printf '%s\n' "${var=$*}"
abc def ghi jkl
printf 'var=%s\n' "$var"
var=abc def ghi jkl
printf '%s\n' "$@"
abc
def ghi
jkl
```

```
set one "" three
printf '[%s]\n' $*
[one]
[] (this line of output is optional)
[three]
printf '[%s]\n' $@
[one]
[] (this line of output is optional)
[three]
```

```
set --
printf '[%s]\n' foo "$*"
[foo]
[]
printf '[%s]\n' foo "$novar$*$(echo)"
[foo]
[]
printf '[%s]\n' foo $@
[foo]
printf '[%s]\n' foo "$@"
[foo]
printf '[%s]\n' foo ''$@
[foo]
[]
printf '[%s]\n' foo ''"$@"
[foo]
[]
printf '[%s]\n' foo "$novar$@$(echo)"
[foo]
[] (this line of output is optional)
printf '[%s]\n' foo ''"$novar$@$(echo)"
[foo]
[]
```

In all of the following commands the results of the expansion of `'@'` (if performed) are unspecified:

```
var=$@
var="$@"
printf '%s\n' ${var=$@}
printf '%s\n' "${var=$@}"
printf '%s\n' ${var="$@"}
printf '%s\n' ${var?$@}
printf '%s\n' "${var?$@}"
```

```
printf '%s\n' ${var?"$@"}
printf '%s\n' ${#@}
printf '%s\n' "${#@}"
printf '%s\n' ${@%foo}
printf '%s\n' "${@%foo}"
printf '%s\n' ${@#foo}
printf '%s\n' "${@#foo}"
printf '%s\n' ${var%$@}
printf '%s\n' "${var%$@}"
printf '%s\n' ${var%"$@"}
printf '%s\n' ${var%%$@}
printf '%s\n' "${var%%$@}"
printf '%s\n' ${var%%"$@"}
printf '%s\n' ${var#$@}
printf '%s\n' "${var#$@}"
printf '%s\n' ${var#"$@"}
printf '%s\n' ${var##$@}
printf '%s\n' "${var##$@}"
printf '%s\n' ${var##"$@"}
```

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0009 [888] is applied.

C.2.5.3 Shell Variables

See the discussion of *IFS* in Section C.2.6.5 (on page 3734) and the RATIONALE for the *sh* utility.

The prohibition on *LC_CTYPE* changes affecting lexical processing protects the shell implementor (and the shell programmer) from the ill effects of changing the definition of <blank> or the set of alphabetic characters in the current environment. It would probably not be feasible to write a compiled version of a shell script without this rule. The rule applies only to the current invocation of the shell and its subshells—invoking a shell script or performing *exec sh* would subject the new shell to the changes in *LC_CTYPE*.

Other common environment variables used by historical shells are not specified by the Shell and Utilities volume of POSIX.1-2017, but they should be reserved for the historical uses.

Tilde expansion for components of *PATH* in an assignment such as:

```
PATH=~hlj/bin:~dwc/bin:$PATH
```

is a feature of some historical shells and is allowed by the wording of XCU Section 2.6.1 (on page 2354). Note that the <tilde> characters are expanded during the assignment to *PATH*, not when *PATH* is accessed during command search.

The following entries represent additional information about variables included in the Shell and Utilities volume of POSIX.1-2017, or rationale for common variables in use by shells that have been excluded:

_ (Underscore.) While <underscore> is historical practice, its overloaded usage in the KornShell is confusing, and it has been omitted from the Shell and Utilities volume of POSIX.1-2017.

ENV This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by *ENV* differs from **$HOME/.profile** in that **.profile** is typically executed at session start-up, whereas the *ENV* file is executed at the beginning of each shell invocation. The *ENV* value is interpreted in a manner similar to a dot script, in that the commands are

executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no *PATH* searching is performed. This is used as a guard against Trojan Horse security breaches.

ERRNO This variable was omitted from the Shell and Utilities volume of POSIX.1-2017 because the values of error numbers are not defined in POSIX.1-2017 in a portable manner.

FCEDIT Since this variable affects only the *fc* utility, it has been omitted from this more global place. The value of *FCEDIT* does not affect the command-line editing mode in the shell; see the description of *set* **−o** *vi* in the *set* built-in utility.

PS1 This variable is used for interactive prompts. Historically, the ``superuser'' has had a prompt of `'#'`. Since privileges are not required to be monolithic, it is difficult to define which privileges should cause the alternate prompt. However, a sufficiently powerful user should be reminded of that power by having an alternate prompt.

PS3 This variable is used by the KornShell for the *select* command. Since the POSIX shell does not include *select*, *PS3* was omitted.

PS4 This variable is used for shell debugging. For example, the following script:

```
PS4='[${LINENO}]+ '
set −x
echo Hello
```

writes the following to standard error:

```
[3]+ echo Hello
```

RANDOM This pseudo-random number generator was not seen as being useful to interactive users.

SECONDS Although this variable is sometimes used with *PS1* to allow the display of the current time in the prompt of the user, it is not one that would be manipulated frequently enough by an interactive user to include in the Shell and Utilities volume of POSIX.1-2017.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0002 [152] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0010 [888], XCU/TC2-2008/0011 [884], and XCU/TC2-2008/0012 [494] are applied.

C.2.6 Word Expansions

Step (2) refers to the ``portions of fields generated by step (1)''. For example, if the word being expanded were `"$x+$y"` and *IFS*=+, the word would be split only if `"$x"` or `"$y"` contained `'+'`; the `'+'` in the original word was not generated by step (1).

IFS is used for performing field splitting on the results of parameter and command substitution; it is not used for splitting all fields. Earlier versions of the shell used it for splitting all fields during field splitting, but this has severe problems because the shell can no longer parse its own script. There are also important security implications caused by this behavior. All useful applications of *IFS* use it for parsing input of the *read* utility and for splitting the results of parameter and command substitution.

The rule concerning expansion to a single field requires that if **foo**=**abc** and **bar**=**def**, that:

```
"$foo""$bar"
```

expands to the single field:

```
abcdef
```

The rule concerning empty fields can be illustrated by:

```
$    unset foo
$    set $foo bar '' xyz "$foo" abc
$    for i
>    do
>        echo "-$i-"
>    done
-bar-
--
-xyz-
--
-abc-
```

Step (1) indicates that parameter expansion, command substitution, and arithmetic expansion are all processed simultaneously as they are scanned. For example, the following is valid arithmetic:

```
x=1
echo $(( $(echo 3)+$x ))
```

An early proposal stated that tilde expansion preceded the other steps, but this is not the case in known historical implementations; if it were, and if a referenced home directory contained a `'$'` character, expansions would result within the directory name.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0003 [49,430] is applied.

C.2.6.1 Tilde Expansion

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

```
PATH=/posix/bin:~dgk/bin
```

This is eligible for tilde expansion because <tilde> follows a <colon> and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:

```
PATH=$(printf %s ~karels/bin : ~bostic/bin)
```

```
for Dir in ~maart/bin ~srb/bin ...
do
    PATH=${PATH:+$PATH:}$Dir
done
```

In the first command, explicit <colon> characters are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.

Note that expressions in operands such as:

```
make -k mumble LIBDIR=~chet/lib
```

do not qualify as shell variable assignments, and tilde expansion is not performed (unless the command does so itself, which *make* does not).

Because of the requirement that the word is not quoted, the following are not equivalent; only the last causes tilde expansion:

127914 `\~hlj/ ~h\lj/ ~"hlj"/ ~hlj\/ ~hlj/`

127915 In an early proposal, tilde expansion occurred following any unquoted <equals-sign> or
127916 <colon>, but this was removed because of its complexity and to avoid breaking commands such
127917 as:

127918 `rcp hostname:~marc/.profile .`

127919 System administrators on systems where **//** has an implementation-defined meaning which is
127920 different to **/**, should not create users with a home directory of **/** or **//**, since this may lead to
127921 unexpected filename resolution on those systems.

127922 A suggestion was made that the special sequence `"$~"` should be allowed to force tilde
127923 expansion anywhere. Since this is not historical practice, it has been left for future
127924 implementations to evaluate. (The description in XCU Section 2.2 (on page 2346) requires that a
127925 <dollar-sign> be quoted to represent itself, so the `"$~"` combination is already unspecified.)

127926 The results of giving <tilde> with an unknown login name are undefined because the KornShell
127927 `"~+"` and `"~−"` constructs make use of this condition, but in general it is an error to give an
127928 incorrect login name with <tilde>. The results of having *HOME* unset are unspecified because
127929 some historical shells treat this as an error.

127930 Historically, the Korn shell performed field splitting and pathname expansion on the results of
127931 tilde expansion, and earlier versions of this standard reflected this. However, tilde expansion
127932 results in a pathname, and performing field splitting and pathname expansion on something
127933 that is already a pathname is at best redundant and at worst will change the value from the
127934 correct pathname to one or more incorrect ones. Later versions of the Korn shell do not perform
127935 these expansions and POSIX.1-2017 has been updated to match. Note that although pathname
127936 expansion is not performed on the results of tilde expansion, this does not prevent other parts of
127937 the same word from being expanded. For example, ~/a* expands to all files in **$HOME**
127938 beginning with `'a'`.

127939 *C.2.6.2 Parameter Expansion*

127940 The rule for finding the closing `'}'` in `"${...}"` is the one used in the KornShell and is
127941 upwardly-compatible with the Bourne shell, which does not determine the closing `'}'` until the
127942 word is expanded. The advantage of this is that incomplete expansions, such as:

127943 `${foo`

127944 can be determined during tokenization, rather than during expansion.

127945 For rationale regarding expansion of `"${...}"` within double-quotes, see Section C.2.2.3 (on
127946 page 3718).

127947 The string length and substring capabilities were included because of the demonstrated need for
127948 them, based on their usage in other shells, such as C shell and KornShell.

127949 Historical versions of the KornShell have not performed tilde expansion on the word part of
127950 parameter expansion; however, it is more consistent to do so.

127951 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0004 [458], XCU/TC1-2008/0005
127952 [458], XCU/TC1-2008/0006 [457], XCU/TC1-2008/0007 [457], XCU/TC1-2008/0008 [417],
127953 XCU/TC1-2008/0009 [457], XCU/TC1-2008/0010 [457], XCU/TC1-2008/0011 [457],
127954 XCU/TC1-2008/0012 [457], XCU/TC1-2008/0013 [457], XCU/TC1-2008/0014 [457],
127955 XCU/TC1-2008/0015 [457], XCU/TC1-2008/0016 [457], XCU/TC1-2008/0017 [457], and
127956 XCU/TC1-2008/0018 [458] are applied.

127957 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0013 [888] and XCU/TC2-2008/0014

[867] are applied.

C.2.6.3 Command Substitution

The "$()" form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

Command	Output
`echo '\$x'`	`\$x`
`echo `echo '\$x'``	`$x`
`echo $(echo '\$x')`	`\$x`

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the newer "$()" form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

```
echo `                          echo $(
cat <<\eof                      cat <<\eof
a here-doc with `               a here-doc with )
eof                             eof
`                               )

echo `                          echo $(
echo abc # a comment with `     echo abc # a comment with )
`                               )

echo `                          echo $(
echo '`'                        echo ')'
`                               )
```

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

The KornShell feature:

> If *command* is of the form <*word*, *word* is expanded to generate a pathname, and the value of the command substitution is the contents of this file with any trailing <newline> characters deleted.

was omitted from the Shell and Utilities volume of POSIX.1-2017 because $(*cat word*) is an appropriate substitute. However, to prevent breaking numerous scripts relying on this feature, it is unspecified to have a script within "$()" that has only redirections.

Arithmetic expansions have precedence over command substitutions. That is, if the shell can parse an expansion beginning with "$((" as an arithmetic expansion then it will do so. It will only parse the expansion as a command substitution (that starts with a subshell) if it determines that it cannot parse the expansion as an arithmetic expansion. If the syntax is valid for neither type of expansion, then it is unspecified what kind of syntax error the shell reports.

How well the shell performs this determination is a quality of implementation issue. Current shell implementations use heuristics. In particular, the shell need not evaluate nested expansions when determining whether it can parse an expansion beginning with "$((" as an arithmetic expansion. For example:

```
$((a $op b))
```

is always an arithmetic expansion if "$op" expands to, say, '+', but if "$op" expands to '(' then the shell might still parse the expansion as an arithmetic expansion (resulting in a syntax error due to unbalanced parentheses) or it might perform a command substitution.

This standard requires that conforming applications always separate the "$(" and '(' with white space when a command substitution starts with a subshell. This is because implementations may support extensions in arithmetic expressions which could result in the shell parsing the input as an arithmetic expansion even though a minimally conforming shell would not. For example, many shells support arrays with the array index (which can be an expression) in square brackets. Therefore, the presence of "myfile[0-9]" within an expansion beginning "$((" is no guarantee that it will be parsed as a command substitution.

The ambiguity is not restricted to the simple case of a single subshell. More complicated ambiguous cases are possible (even with just the standard shell syntax), such as:

```
$(( cat <<EOH
+ ( (
EOH
) && ( cat <<EOH
) ) + 1 +
EOH
))
```

This can be parsed as an arithmetic expansion, with *cat* and *EOH* as the names of shell variables. Ambiguous cases also exist where the end of the expansion is at a different location for the arithmetic expansion and the command substitution:

```
$((cat <<EOF
+((((
EOF
) && (
cat <<EOF
+
EOF
))
```

This is an incomplete arithmetic expansion, but would have been a (complete) command substitution if it could not have been parsed as an arithmetic expansion. If this expansion occurs at the end of input then the shell reports a syntax error; it does not parse it as a command substitution.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/4 is applied, changing the text from: ``If a command substitution occurs inside double-quotes, it shall not be performed on the results of the substitution.'' to: ``If a command substitution occurs inside double-quotes, field splitting and pathname expansion shall not be performed on the results of the substitution.''. The replacement text taken from the ISO POSIX-2: 1993 standard is clearer about the items that are not performed.

SD5-XCU-ERN-84 is applied, clarifying how the search for the matching backquote is satisfied.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0019 [217] is applied.

C.2.6.4 Arithmetic Expansion

The standard developers agreed that there was a strong desire for some kind of arithmetic evaluator to provide functionality similar to *expr*, that relating it to `'$'` makes it work well with the standard shell language and provides access to arithmetic evaluation in places where accessing a utility would be inconvenient.

The syntax and semantics for arithmetic were revised for the ISO/IEC 9945-2:1993 standard. The language represents a simple subset of the previous arithmetic language (which was derived from the KornShell `"(())"` construct). The syntax was changed from that of a command denoted by ((*expression*)) to an expansion denoted by $((*expression*)). The new form is a dollar expansion (`'$'`) that evaluates the expression and substitutes the resulting value. Objections to the previous style of arithmetic included that it was too complicated, did not fit in well with the use of variables in the shell, and its syntax conflicted with subshells. The justification for the new syntax is that the shell is traditionally a macro language, and if a new feature is to be added, it should be accomplished by extending the capabilities presented by the current model of the shell, rather than by inventing a new one outside the model; adding a new dollar expansion was perceived to be the most intuitive and least destructive way to add such a new capability.

The standard requires assignment operators to be supported (as listed in XCU Section 1.1.2, on page 2331), and since arithmetic expansions are not specified to be evaluated in a subshell environment, changes to variables there have to be in effect after the arithmetic expansion, just as in the parameter expansion `"${x=value}"`.

Note, however, that `"$(( x=5 ))"` need not be equivalent to `"$(( $x=5 ))"`. If the value of the environment variable *x* is the string `"y="`, the expansion of `"$(( x=5 ))"` would set *x* to 5 and output 5, but `"$(( $x=5 ))"` would output 0 if the value of the environment variable *y* is not 5 and would output 1 if the environment variable *y* is 5. Similarly, if the value of the environment variable is 4, the expansion of `"$(( x=5 ))"` would still set *x* to 5 and output 5, but `"$(( $x=5 ))"` (which would be equivalent to `"$(( 4=5 ))"`) would yield a syntax error.

In early proposals, a form $[*expression*] was used. It was functionally equivalent to the `"$(())"` of the current text, but objections were lodged that the 1988 KornShell had already implemented `"$(())"` and there was no compelling reason to invent yet another syntax. Furthermore, the `"$[]"` syntax had a minor incompatibility involving the patterns in **case** statements.

The portion of the ISO C standard arithmetic operations selected corresponds to the operations historically supported in the KornShell. In addition to the exceptions listed in XCU Section 2.6.4 (on page 2358), the use of the following are explicitly outside the scope of the rules defined in XCU Section 1.1.2.1 (on page 2331):

> The prefix operator `'&'` and the `"[]"`, `"->"`, and `'.'` operators.
>
> Casts

It was concluded that the *test* command ([) was sufficient for the majority of relational arithmetic tests, and that tests involving complicated relational expressions within the shell are rare, yet could still be accommodated by testing the value of `"$(())"` itself. For example:

```
# a complicated relational expression
while [ $(( (($x + $y)/($a * $b)) < ($foo*$bar) )) -ne 0 ]
```

or better yet, the rare script that has many complex relational expressions could define a function like this:

```
val() {
    return $((!$1))
```

```
}
```

and complicated tests would be less intimidating:

```
while val $(( (($x + $y)/($a * $b)) < ($foo*$bar) ))
do
    # some calculations
done
```

A suggestion that was not adopted was to modify *true* and *false* to take an optional argument, and *true* would exit true only if the argument was non-zero, and *false* would exit false only if the argument was non-zero:

```
while true $(($x > 5 && $y <= 25))
```

There is a minor portability concern with the new syntax. The example `"$((2+2))"` could have been intended to mean a command substitution of a utility named `"2+2"` in a subshell. The standard developers considered this to be obscure and isolated to some KornShell scripts (because `"$()"` command substitution existed previously only in the KornShell). The text on command substitution requires that the `"$("` and `'('` be separate tokens if this usage is needed.

An example such as:

```
echo $((echo hi);(echo there))
```

should not be misinterpreted by the shell as arithmetic because attempts to balance the parentheses pairs would indicate that they are subshells. However, as indicated by XBD Section 3.113 (on page 51), a conforming application must separate two adjacent parentheses with white space to indicate nested subshells.

The standard is intentionally silent about how a variable's numeric value in an expression is determined from its normal ``sequence of bytes'' value. It could be done as a text substitution, as a conversion like that performed by *strtol*(), or even recursive evaluation. Therefore, the only cases for which the standard is clear are those for which both conversions produce the same result. The cases where they give the same result are those where the sequence of bytes form a valid integer constant. Therefore, if a variable does not contain a valid integer constant, the behavior is unspecified.

For the commands:

```
x=010; echo $((x += 1))
```

the output must be 9.

For the commands:

```
x=' 1'; echo $((x += 1))
```

the results are unspecified.

For the commands:

```
x=1+1; echo $((x += 1))
```

the results are unspecified.

Although the ISO/IEC 9899:1999 standard now requires support for **long long** and allows extended integer types with higher ranks, POSIX.1-2017 only requires arithmetic expansions to support **signed long** integer arithmetic. Implementations are encouraged to support signed integer values at least as large as the size of the largest file allowed on the implementation.

Implementations are also allowed to perform floating-point evaluations as long as an

application won't see different results for expressions that would not overflow **signed long** integer expression evaluation. (This includes appropriate truncation of results to integer values.)

Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement that the integer constant suffixes `l` and `L` had to be recognized. The ISO POSIX-2: 1993 standard did not require the `u`, `ul`, `uL`, `U`, `Ul`, `UL`, `lu`, `lU`, `Lu`, and `LU` suffixes since only signed integer arithmetic was required. Since all arithmetic expressions were treated as handling **signed long** integer types anyway, the `l` and `L` suffixes were redundant. No known scripts used them and some historic shells did not support them. When the ISO/IEC 9899: 1999 standard was used as the basis for the description of arithmetic processing, the `ll` and `LL` suffixes and combinations were also not required. Implementations are still free to accept any or all of these suffixes, but are not required to do so.

There was also some confusion as to whether the shell was required to recognize character constants. Syntactically, character constants were required to be recognized, but the requirements for the handling of <backslash> and single-quote characters (needed to specify character constants) within an arithmetic expansion were ambiguous. Furthermore, no known shells supported them. Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement to support them (if they were indeed required before). POSIX.1-2017 clearly does not require support for character constants.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/3 is applied, clarifying arithmetic expressions.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0020 [50] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0015 [584] is applied.

C.2.6.5 Field Splitting

The operation of field splitting using *IFS*, as described in early proposals, was based on the way the KornShell splits words, but it is incompatible with other common versions of the shell. However, each has merit, and so a decision was made to allow both. If the *IFS* variable is unset or is <space><tab><newline>, the operation is equivalent to the way the System V shell splits words. Using characters outside the <space><tab><newline> set yields the KornShell behavior, where each of the non-<space><tab><newline>s is significant. This behavior, which affords the most flexibility, was taken from the way the original *awk* handled field splitting.

Rule (3) can be summarized as a pseudo-ERE:

`(`*s*`*`*n*`*`s`*`*|`*s*`+)`

where *s* is an *IFS* white-space character and *n* is a character in the *IFS* that is not white space. Any string matching that ERE delimits a field, except that the *s*+ form does not delimit fields at the beginning or the end of a line. For example, if *IFS* is <space>/<comma>/<tab>, the string:

`<space><space>red<space><space>,<space>white<space>blue`

yields the three colors as the delimited fields.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0016 [832] is applied.

C.2.6.6 Pathname Expansion

There is no additional rationale provided for this section.

C.2.6.7 Quote Removal

There is no additional rationale provided for this section.

C.2.7 Redirection

In the System Interfaces volume of POSIX.1-2017, file descriptors are integers in the range 0–({OPEN_MAX}–1). The file descriptors discussed in XCU Section 2.7 (on page 2360) are that same set of small integers.

Having multi-digit file descriptor numbers for I/O redirection can cause some obscure compatibility problems. Specifically, scripts that depend on an example command:

```
echo 22>/dev/null
```

echoing "2" to standard error or "22" to standard output are no longer portable. However, the file descriptor number must still be delimited from the preceding text. For example:

```
cat file2>foo
```

writes the contents of **file2**, not the contents of **file**.

The ">|" format of output redirection was adopted from the KornShell. Along with the *noclobber* option, *set* **–C**, it provides a safety feature to prevent inadvertent overwriting of existing files. (See the RATIONALE for the *pathchk* utility for why this step was taken.) The restriction on regular files is historical practice.

The System V shell and the KornShell have differed historically on pathname expansion of *word*; the former never performed it, the latter only when the result was a single field (file). As a compromise, it was decided that the KornShell functionality was useful, but only as a shorthand device for interactive users. No reasonable shell script would be written with a command such as:

```
cat foo > a*
```

Thus, shell scripts are prohibited from doing it, while interactive users can select the shell with which they are most comfortable.

The construct "2>&1" is often used to redirect standard error to the same file as standard output. Since the redirections take place beginning to end, the order of redirections is significant. For example:

```
ls > foo 2>&1
```

directs both standard output and standard error to file **foo**. However:

```
ls 2>&1 > foo
```

only directs standard output to file **foo** because standard error was duplicated as standard output before standard output was directed to file **foo**.

Applications should not use the [*n*]<&– or [*n*]>&– operators to execute a utility or application with file descriptor 0 not open for reading or with file descriptor 1 or 2 not open for writing, as this might cause the executed program (or shell built-in) to misbehave. In order not to pass on these file descriptors to an executed utility or application, applications should not just close them but should reopen them on, for example, **/dev/null**. Some implementations may reopen

128211 them automatically, but applications should not rely on this being done.

128212 The "<>" operator could be useful in writing an application that worked with several terminals,
128213 and occasionally wanted to start up a shell. That shell would in turn be unable to run
128214 applications that run from an ordinary controlling terminal unless it could make use of "<>"
128215 redirection. The specific example is a historical version of the pager *more*, which reads from
128216 standard error to get its commands, so standard input and standard output are both available
128217 for their usual usage. There is no way of saying the following in the shell without "<>":

128218
```
cat food | more - >/dev/tty03 2<>/dev/tty03
```

128219 Another example of "<>" is one that opens **/dev/tty** on file descriptor 3 for reading and writing:

128220
```
exec 3<> /dev/tty
```

128221 An example of creating a lock file for a critical code region:

128222
```
set -C
128223 until    2> /dev/null > lockfile
128224 do       sleep 30
128225 done
128226 set +C
128227 perform critical function
128228 rm lockfile
```

128229 Since **/dev/null** is not a regular file, no error is generated by redirecting to it in *noclobber* mode.

128230 Tilde expansion is not performed on a here-document because the data is treated as if it were
128231 enclosed in double-quotes.

128232 C.2.7.1 *Redirecting Input*

128233 There is no additional rationale provided for this section.

128234 C.2.7.2 *Redirecting Output*

128235 There is no additional rationale provided for this section.

128236 C.2.7.3 *Appending Redirected Output*

128237 Note that when a file is opened (even with the O_APPEND flag set), the initial file offset for that
128238 file is set to the beginning of the file. Some historic shells set the file offset to the current end-of-
128239 file when **append** mode shell redirection was used, but this is not allowed by POSIX.1-2017.

128240 C.2.7.4 *Here-Document*

128241 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0017 [890], XCU/TC2-2008/0018
128242 [583], and XCU/TC2-2008/0019 [580] are applied.

128243 C.2.7.5 *Duplicating an Input File Descriptor*

128244 There is no additional rationale provided for this section.

128245 *C.2.7.6 Duplicating an Output File Descriptor*

128246 There is no additional rationale provided for this section.

128247 *C.2.7.7 Open File Descriptors for Reading and Writing*

128248 There is no additional rationale provided for this section.

128249 C.2.8 Exit Status and Errors

128250 There is no additional rationale provided for this section.

128251 *C.2.8.1 Consequences of Shell Errors*

128252 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0020 [882] and XCU/TC2-2008/0021
128253 [717,882] are applied.

128254 *C.2.8.2 Exit Status for Commands*

128255 There is a historical difference in *sh* and *ksh* non-interactive error behavior. When a command
128256 named in a script is not found, some implementations of *sh* exit immediately, but *ksh* continues
128257 with the next command. Thus, the Shell and Utilities volume of POSIX.1-2017 says that the shell
128258 ``may'' exit in this case. This puts a small burden on the programmer, who has to test for
128259 successful completion following a command if it is important that the next command not be
128260 executed if the previous command was not found. If it is important for the command to have
128261 been found, it was probably also important for it to complete successfully. The test for successful
128262 completion would not need to change.

128263 Historically, shells have returned an exit status of 128+*n*, where *n* represents the signal number.
128264 Since signal numbers are not standardized, there is no portable way to determine which signal
128265 caused the termination. Also, it is possible for a command to exit with a status in the same range
128266 of numbers that the shell would use to report that the command was terminated by a signal.
128267 Implementations are encouraged to choose exit values greater than 256 to indicate programs that
128268 terminate by a signal so that the exit status cannot be confused with an exit status generated by a
128269 normal termination.

128270 Historical shells make the distinction between ``utility not found'' and ``utility found but cannot
128271 execute'' in their error messages. By specifying two seldomly used exit status values for these
128272 cases, 127 and 126 respectively, this gives an application the opportunity to make use of this
128273 distinction without having to parse an error message that would probably change from locale to
128274 locale. The *command*, *env*, *nohup*, and *xargs* utilities in the Shell and Utilities volume of
128275 POSIX.1-2017 have also been specified to use this convention.

128276 When a command fails during word expansion or redirection, most historical implementations
128277 exit with a status of 1. However, there was some sentiment that this value should probably be
128278 much higher so that an application could distinguish this case from the more normal exit status
128279 values. Thus, the language ``greater than zero'' was selected to allow either method to be
128280 implemented.

128281 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0022 [717] is applied.

C.2.9 Shell Commands

A description of an ``empty command'' was removed from an early proposal because it is only relevant in the cases of *sh* **−c ""**, *system*(""), or an empty shell-script file (such as the implementation of *true* on some historical systems). Since it is no longer mentioned in the Shell and Utilities volume of POSIX.1-2017, it falls into the silently unspecified category of behavior where implementations can continue to operate as they have historically, but conforming applications do not construct empty commands. (However, note that *sh* does explicitly state an exit status for an empty string or file.) In an interactive session or a script with other commands, extra <newline> or <semicolon> characters, such as:

```
$ false
$
$ echo $?
1
```

would not qualify as the empty command described here because they would be consumed by other parts of the grammar.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0023 [473] is applied.

C.2.9.1 Simple Commands

The enumerated list is used only when the command is actually going to be executed. For example, in:

```
true || $foo *
```

no expansions are performed.

The following example illustrates both how a variable assignment without a command name affects the current execution environment, and how an assignment with a command name only affects the execution environment of the command:

```
$ x=red
$ echo $x
red
$ export x
$ sh −c 'echo $x'
red
$ x=blue sh −c 'echo $x'
blue
$ echo $x
red
```

This next example illustrates that redirections without a command name are still performed:

```
$ ls foo
ls: foo: no such file or directory
$ > foo
$ ls foo
foo
```

A command without a command name, but one that includes a command substitution, has an exit status of the last command substitution that the shell performed. For example:

```
if      x=$(command)
then    ...
fi
```

An example of redirections without a command name being performed in a subshell shows that the here-document does not disrupt the standard input of the **while** loop:

```
IFS=:
while    read a b
do       echo $a
         <<-eof
         Hello
         eof
done </etc/passwd
```

Following are examples of commands without command names in AND-OR lists:

```
> foo || {
    echo "error: foo cannot be created" >&2
    exit 1
}
# set saved if /vmunix.save exists
test -f /vmunix.save && saved=1
```

Command substitution and redirections without command names both occur in subshells, but they are not necessarily the same ones. For example, in:

```
exec 3> file
var=$(echo foo >&3) 3>&1
```

it is unspecified whether **foo** is echoed to the file or to standard output.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0021 [255] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0024 [654] is applied.

Command Search and Execution

This description requires that the shell can execute shell scripts directly, even if the underlying system does not support the common `"#!"` interpreter convention. That is, if file **foo** contains shell commands and is executable, the following executes **foo**:

```
./foo
```

The command search shown here does not match all historical implementations. A more typical sequence has been:

> Any built-in (special or regular)
>
> Functions
>
> Path search for executable files

But there are problems with this sequence. Since the programmer has no idea in advance which utilities might have been built into the shell, a function cannot be used to override portably a utility of the same name. (For example, a function named *cd* cannot be written for many historical systems.) Furthermore, the *PATH* variable is partially ineffective in this case, and only a pathname with a <slash> can be used to ensure a specific executable file is invoked.

After the *execve*( ) failure described, the shell normally executes the file as a shell script. Some implementations, however, attempt to detect whether the file is actually a script and not an executable from some other architecture. The method used by the KornShell is allowed by the text that indicates non-text files may be bypassed.

The sequence selected for the Shell and Utilities volume of POSIX.1-2017 acknowledges that special built-ins cannot be overridden, but gives the programmer full control over which versions of other utilities are executed. It provides a means of suppressing function lookup (via the *command* utility) for the user's own functions and ensures that any regular built-ins or functions provided by the implementation are under the control of the path search. The mechanisms for associating built-ins or functions with executable files in the path are not specified by the Shell and Utilities volume of POSIX.1-2017, but the wording requires that if either is implemented, the application is not able to distinguish a function or built-in from an executable (other than in terms of performance, presumably). The implementation ensures that all effects specified by the Shell and Utilities volume of POSIX.1-2017 resulting from the invocation of the regular built-in or function (interaction with the environment, variables, traps, and so on) are identical to those resulting from the invocation of an executable file.

Various historical implementations have used the names in item 1.b. as built-ins or reserved words. This standard does not specify their behavior, but their existence means that it is important for portable applications to avoid giving functions (or utilities in *PATH*) those names because the function (or utility in *PATH*) might not be executed as expected.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/4 is applied, updating the case where *execve*( ) fails due to an error equivalent to the [ENOEXEC] error.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0022 [168], XCU/TC1-2008/0023 [168], XCU/TC1-2008/0024 [168], XCU/TC1-2008/0025 [168], XCU/TC1-2008/0026 [168,430], XCU/TC1-2008/0027 [168,430], and XCU/TC1-2008/0028 [173] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0025 [935] and XCU/TC2-2008/0026 [705] are applied.

Examples

Consider three versions of the *ls* utility:

1. The application includes a shell function named *ls*.
2. The user writes a utility named *ls* and puts it in **/fred/bin**.
3. The example implementation provides *ls* as a regular shell built-in that is invoked (either by the shell or directly by *exec*) when the path search reaches the directory **/posix/bin**.

If *PATH*=**/posix/bin**, various invocations yield different versions of *ls*:

Invocation	**Version of** *ls*
ls (from within application script)	(1) function
command ls (from within application script)	(3) built-in
ls (from within makefile called by application)	(3) built-in
system("*ls*")	(3) built-in
PATH="**/fred/bin**:$*PATH*" *ls*	(2) user's version

C.2.9.2 Pipelines

Because pipeline assignment of standard input or standard output or both takes place before redirection, it can be modified by redirection. For example:

```
$ command1 2>&1 | command2
```

sends both the standard output and standard error of *command1* to the standard input of *command2*.

The reserved word **!** allows more flexible testing using AND and OR lists. The behavior of **!(** is unspecified because in the Korn Shell this introduces a negated pathname expansion. Portable applications need to separate the **!** and **(** to ensure the command is treated as a negated subshell.

It was suggested that it would be better to return a non-zero value if any command in the pipeline terminates with non-zero status (perhaps the bitwise-inclusive OR of all return values). However, the choice of the last-specified command semantics are historical practice and would cause applications to break if changed. An example of historical behavior:

```
$ sleep 5 | (exit 4)
$ echo $?
4
$ (exit 4) | sleep 5
$ echo $?
0
```

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0029 [205] is applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0027 [521] is applied.

Exit Status

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0030 [52] is applied.

C.2.9.3 Lists

The equal precedence of "`&&`" and "`||`" is historical practice. The standard developers evaluated the model used more frequently in high-level programming languages, such as C, to allow the shell logical operators to be used for complex expressions in an unambiguous way, but they could not allow historical scripts to break in the subtle way unequal precedence might cause. Some arguments were posed concerning the "`{}`" or "`()`" groupings that are required historically. There are some disadvantages to these groupings:

> The "`()`" can be expensive, as they spawn other processes on some implementations. This performance concern is primarily an implementation issue.
>
> The "`{}`" braces are not operators (they are reserved words) and require a trailing <space> after each '`{`', and a <semicolon> before each '`}`'. Most programmers (and certainly interactive users) have avoided braces as grouping constructs because of the problematic syntax required. Braces were not changed to operators because that would generate compatibility issues even greater than the precedence question; braces appear outside the context of a keyword in many shell scripts.

IEEE PASC Interpretation 1003.2 #204 is applied, clarifying that the operators "`&&`" and "`||`" are evaluated with left associativity.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0031 [45] and XCU/TC1-2008/0032 [45] are applied.

128447 **Asynchronous Lists**

128448 The grammar treats a construct such as:

128449 ```
foo & bar & bam &
```

128450 as one ``asynchronous list'', but since the status of each element is tracked by the shell, the term
128451 ``element of an asynchronous list'' was introduced to identify just one of the **foo**, **bar**, or **bam**
128452 portions of the overall list.

128453 Unless the implementation has an internal limit, such as {CHILD_MAX}, on the retained process
128454 IDs, it would require unbounded memory for the following example:

128455 ```
while true
128456 do      foo & echo $!
128457 done
```

128458 The treatment of the signals SIGINT and SIGQUIT with asynchronous lists is described in XCU
128459 Section 2.11 (on page 2381).

128460 Since the connection of the input to the equivalent of **/dev/null** is considered to occur before
128461 redirections, the following script would produce no output:

128462 ```
exec < /etc/passwd
128463 cat <&0 &
128464 wait
```

128465 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0028 [760] is applied.

128466 **Sequential Lists**

128467 There is no additional rationale provided for this section.

128468 **AND Lists**

128469 There is no additional rationale provided for this section.

128470 **OR Lists**

128471 There is no additional rationale provided for this section.

  
```

128472 *C.2.9.4 Compound Commands*

128473 **Grouping Commands**

128474 The semicolon shown in {*compound-list*;} is an example of a control operator delimiting the }
128475 reserved word. Other delimiters are possible, as shown in XCU Section 2.10 (on page 2375);
128476 <newline> is frequently used.

128477 A proposal was made to use the **<do-done>** construct in all cases where command grouping in
128478 the current process environment is performed, identifying it as a construct for the grouping
128479 commands, as well as for shell functions. This was not included because the shell already has a
128480 grouping construct for this purpose ("`{}`"), and changing it would have been counter-
128481 productive.

128482 The requirement for conforming applications to separate two leading '`(`' characters with white
128483 space if a grouping command would be parsed as an arithmetic expansion if preceded by a '`$`'
128484 is to allow shells which implement the "`(( arithmetic expression ))`" extension to
128485 apply the same disambiguation rules consistently to `$((...))` and `((...))`. See Section
128486 C.2.6.3 (on page 3730).

128487 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0033 [217] is applied.

128488 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0029 [473] is applied.

128489 **For Loop**

128490 The format is shown with generous usage of <newline> characters. See the grammar in XCU
128491 Section 2.10 (on page 2375) for a precise description of where <newline> and <semicolon>
128492 characters can be interchanged.

128493 Some historical implementations support '`{`' and '`}`' as substitutes for **do** and **done**. The
128494 standard developers chose to omit them, even as an obsolescent feature. (Note that these
128495 substitutes were only for the **for** command; the **while** and **until** commands could not use them
128496 historically because they are followed by compound-lists that may contain "`{...}`" grouping
128497 commands themselves.)

128498 The reserved word pair **do** ... **done** was selected rather than **do** ... **od** (which would have
128499 matched the spirit of **if** ... **fi** and **case** ... **esac**) because *od* is already the name of a standard
128500 utility.

128501 PASC Interpretation 1003.2 #169 has been applied changing the grammar.

128502 **Case Conditional Construct**

128503 An optional <left-parenthesis> before *pattern* was added to allow numerous historical KornShell
128504 scripts to conform. At one time, using the leading parenthesis was required if the **case** statement
128505 was to be embedded within a "`$()`" command substitution; this is no longer the case with the
128506 POSIX shell. Nevertheless, many historical scripts use the <left-parenthesis>, if only because it
128507 makes matching-parenthesis searching easier in *vi* and other editors. This is a relatively simple
128508 implementation change that is upwards-compatible for all scripts.

128509 Consideration was given to requiring *break* inside the *compound-list* to prevent falling through to
128510 the next pattern action list. This was rejected as being nonexisting practice. An interesting
128511 undocumented feature of the KornShell is that using "`;&`" instead of "`;;`" as a terminator
128512 causes the exact opposite behavior—the flow of control continues with the next *compound-list*.

128513 The pattern '`*`', given as the last pattern in a **case** construct, is equivalent to the default case in
128514 a C-language **switch** statement.

128515 The grammar shows that reserved words can be used as patterns, even if one is the first word on

a line. Obviously, the reserved word **esac** cannot be used in this manner.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0029 [473] is applied.

If Conditional Construct

The precise format for the command syntax is described in XCU Section 2.10 (on page 2375).

While Loop

The precise format for the command syntax is described in XCU Section 2.10 (on page 2375).

Until Loop

The precise format for the command syntax is described in XCU Section 2.10 (on page 2375).

C.2.9.5 *Function Definition Command*

The description of functions in an early proposal was based on the notion that functions should behave like miniature shell scripts; that is, except for sharing variables, most elements of an execution environment should behave as if they were a new execution environment, and changes to these should be local to the function. For example, traps and options should be reset on entry to the function, and any changes to them do not affect the traps or options of the caller. There were numerous objections to this basic idea, and the opponents asserted that functions were intended to be a convenient mechanism for grouping common commands that were to be executed in the current execution environment, similar to the execution of the *dot* special built −in.

It was also pointed out that the functions described in that early proposal did not provide a local scope for everything a new shell script would, such as the current working directory, or *umask*, but instead provided a local scope for only a few select properties. The basic argument was that if a local scope is needed for the execution environment, the mechanism already existed: the application can put the commands in a new shell script and call that script. All historical shells that implemented functions, other than the KornShell, have implemented functions that operate in the current execution environment. Because of this, traps and options have a global scope within a shell script. Local variables within a function were considered and included in another early proposal (controlled by the special built-in *local*), but were removed because they do not fit the simple model developed for functions and because there was some opposition to adding yet another new special built-in that was not part of historical practice. Implementations should reserve the identifier *local* (as well as *typeset*, as used in the KornShell) in case this local variable mechanism is adopted in a future version of this standard.

A separate issue from the execution environment of a function is the availability of that function to child shells. A few objectors maintained that just as a variable can be shared with child shells by exporting it, so should a function. In early proposals, the *export* command therefore had a **−f** flag for exporting functions. Functions that were exported were to be put into the environment as *name*( )=*value* pairs, and upon invocation, the shell would scan the environment for these and automatically define these functions. This facility was strongly opposed and was omitted. Some of the arguments against exportable functions were as follows:

> There was little historical practice. The Ninth Edition shell provided them, but there was controversy over how well it worked.
>
> There are numerous security problems associated with functions appearing in the environment of a user and overriding standard utilities or the utilities owned by the application.

There was controversy over requiring *make* to import functions, where it has historically used an *exec* function for many of its command line executions.

Functions can be big and the environment is of a limited size. (The counter-argument was that functions are no different from variables in terms of size: there can be big ones, and there can be small ones ‡and just as one does not export huge variables, one does not export huge functions. However, this might not apply to the average shell-function writer, who typically writes much larger functions than variables.)

As far as can be determined, the functions in the Shell and Utilities volume of POSIX.1-2017 match those in System V. Earlier versions of the KornShell had two methods of defining functions:

```
function fname { compound-list }
```

and:

```
fname() { compound-list }
```

The latter used the same definition as the Shell and Utilities volume of POSIX.1-2017, but differed in semantics, as described previously. The current edition of the KornShell aligns the latter syntax with the Shell and Utilities volume of POSIX.1-2017 and keeps the former as is.

The name space for functions is limited to that of a *name* because of historical practice. Complications in defining the syntactic rules for the function definition command and in dealing with known extensions such as the `"@()"` usage in the KornShell prevented the name space from being widened to a *word*. Using functions to support synonyms such as the `"!!"` and `'%'` usage in the C shell is thus disallowed to conforming applications, but acceptable as an extension. For interactive users, the aliasing facilities in the Shell and Utilities volume of POSIX.1-2017 should be adequate for this purpose. It is recognized that the name space for utilities in the file system is wider than that currently supported for functions, if the portable filename character set guidelines are ignored, but it did not seem useful to mandate extensions in systems for so little benefit to conforming applications.

The `"()"` in the function definition command consists of two operators. Therefore, intermixing <blank> characters with the *fname*, `'('`, and `')'` is allowed, but unnecessary.

An example of how a function definition can be used wherever a simple command is allowed:

```
# If variable i is equal to "yes",
# define function foo to be ls -l
#
[ "$i" = yes ] && foo() {
    ls -l
}
```

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0034 [383] and XCU/TC1-2008/0035 [214] are applied.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0029 [473] and XCU/TC2-2008/0030 [654] are applied.

C.2.10 Shell Grammar

There are several subtle aspects of this grammar where conventional usage implies rules about the grammar that in fact are not true.

For *compound_list*, only the forms that end in a *separator* allow a reserved word to be recognized, so usually only a *separator* can be used where a compound list precedes a reserved word (such as **Then**, **Else**, **Do**, and **Rbrace**). Explicitly requiring a separator would disallow such valid (if rare) statements as:

```
if (false) then (echo x) else (echo y) fi
```

See the Note under special grammar rule (1).

Concerning the third sentence of rule (1) (``Also, if the parser ...''):

> This sentence applies rather narrowly: when a compound list is terminated by some clear delimiter (such as the closing **fi** of an inner **if_clause**) then it would apply; where the compound list might continue (as in after a `';'`), rule (7a) (and consequently the first sentence of rule (1)) would apply. In many instances the two conditions are identical, but this part of rule (1) does not give license to treating a **WORD** as a reserved word unless it is in a place where a reserved word has to appear.
>
> The statement is equivalent to requiring that when the LR(1) lookahead set contains exactly one reserved word, it must be recognized if it is present. (Here ``LR(1)'' refers to the theoretical concepts, not to any real parser generator.)
>
> For example, in the construct below, and when the parser is at the point marked with `'^'`, the only next legal token is **then** (this follows directly from the grammar rules):
>
> ```
> if if...fi then ... fi
>            ^
> ```
>
> At that point, the **then** must be recognized as a reserved word.
>
> (Depending on the parser generator actually used, ``extra'' reserved words may be in some lookahead sets. It does not really matter if they are recognized, or even if any possible reserved word is recognized in that state, because if it is recognized and is not in the (theoretical) LR(1) lookahead set, an error is ultimately detected. In the example above, if some other reserved word (for example, **while**) is also recognized, an error occurs later.
>
> This is approximately equivalent to saying that reserved words are recognized after other reserved words (because it is after a reserved word that this condition occurs), but avoids the ``except for ...'' list that would be required for **case**, **for**, and so on. (Reserved words are of course recognized anywhere a *simple_command* can appear, as well. Other rules take care of the special cases of non-recognition, such as rule (4) for **case** statements.)

Note that the body of here-documents are handled by token recognition (see XCU Section 2.3, on page 2347) and do not appear in the grammar directly. (However, the here-document I/O redirection operator is handled as part of the grammar.)

C.2.10.1 *Shell Grammar Lexical Conventions*

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0031 [648] and XCU/TC2-2008/0032 [574,646] are applied.

128638 *C.2.10.2 Shell Grammar Rules*

128639 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0036 [44] is applied.

128640 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0033 [643,839], XCU/TC2-2008/0034
128641 [643], XCU/TC2-2008/0035 [648], XCU/TC2-2008/0036 [736], XCU/TC2-2008/0037 [737],
128642 XCU/TC2-2008/0038 [581], and XCU/TC2-2008/0039 [735] are applied.

128643 ## C.2.11 Signals and Error Handling

128644 Historically, some shell implementations silently ignored attempts to use *trap* to set SIGINT or
128645 SIGQUIT to the default action or to set a trap for them after they have been set to be ignored by
128646 the shell when it executes an asynchronous subshell (and job control is disabled). This behavior
128647 is not conforming. For example, if a shell script containing the following line is run in the
128648 foreground at a terminal:

128649 ```
(trap - INT; exec sleep 10) & wait
```

128650 and is then terminated by typing the interrupt character, this standard requires that the *sleep*
128651 command is terminated by the SIGINT signal.

128652 SD5-XCU-ERN-93 is applied, updating the first paragraph of XCU Section 2.11 (on page 2381).

128653 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0040 [750] is applied.

128654 ## C.2.12 Shell Execution Environment

128655 Some implementations have implemented the last stage of a pipeline in the current environment
128656 so that commands such as:

128657 ```
command | read foo
```

128658 set variable **foo** in the current environment. This extension is allowed, but not required;
128659 therefore, a shell programmer should consider a pipeline to be in a subshell environment, but
128660 not depend on it.

128661 In early proposals, the description of execution environment failed to mention that each
128662 command in a multiple command pipeline could be in a subshell execution environment. For
128663 compatibility with some historical shells, the wording was phrased to allow an implementation
128664 to place any or all commands of a pipeline in the current environment. However, this means that
128665 a POSIX application must assume each command is in a subshell environment, but not depend
128666 on it.

128667 The wording about shell scripts is meant to convey the fact that describing ``trap actions'' can
128668 only be understood in the context of the shell command language. Outside of this context, such
128669 as in a C-language program, signals are the operative condition, not traps.

128670 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0037 [238] is applied.

128671 POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0041 [706] is applied.

C.2.13 Pattern Matching Notation

Pattern matching is a simpler concept and has a simpler syntax than REs, as the former is generally used for the manipulation of filenames, which are relatively simple collections of characters, while the latter is generally used to manipulate arbitrary text strings of potentially greater complexity. However, some of the basic concepts are the same, so this section points liberally to the detailed descriptions in XBD Chapter 9 (on page 181).

C.2.13.1 *Patterns Matching a Single Character*

Both quoting and escaping are described here because pattern matching must work in three separate circumstances:

1. Calling directly upon the shell, such as in pathname expansion or in a **case** statement. All of the following match the string or file **abc**:

   ```
   abc "abc" a"b"c a\bc a[b]c a["b"]c a[\b]c a["\b"]c a?c a*c
   ```

   The following do not:

   ```
   "a?c" a\*c a\[b]c
   ```

2. Calling a utility or function without going through a shell, as described for *find* and the *fnmatch*( ) function defined in the System Interfaces volume of POSIX.1-2017.

3. Calling utilities such as *find*, *cpio*, *tar*, or *pax* through the shell command line. In this case, shell quote removal is performed before the utility sees the argument. For example, in:

   ```
   find /bin -name "e\c[\h]o" -print
   ```

   after quote removal, the <backslash> characters are presented to *find* and it treats them as escape characters. Both precede ordinary characters, so the *c* and *h* represent themselves and *echo* would be found on many historical systems (that have it in **/bin**). To find a filename that contained shell special characters or pattern characters, both quoting and escaping are required, such as:

   ```
   pax -r ... "*a\(\?"
   ```

   to extract a filename ending with `"a(?"`.

Conforming applications are required to quote or escape the shell special characters (sometimes called metacharacters). If used without this protection, syntax errors can result or implementation extensions can be triggered. For example, the KornShell supports a series of extensions based on parentheses in patterns.

The restriction on a <circumflex> in a bracket expression is to allow implementations that support pattern matching using the <circumflex> as the negation character in addition to the <exclamation-mark>. A conforming application must use something like `"[\^!]"` to match either character.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0042 [806] is applied.

C.2.13.2 *Patterns Matching Multiple Characters*

Since each <asterisk> matches zero or more occurrences, the patterns `"a*b"` and `"a**b"` have identical functionality.

Examples

`a[bc]`	Matches the strings `"ab"` and `"ac"`.
`a*d`	Matches the strings `"ad"`, `"abd"`, and `"abcd"`, but not the string `"abc"`.
`a*d*`	Matches the strings `"ad"`, `"abcd"`, `"abcdef"`, `"aaaad"`, and `"adddd"`.
`*a*d`	Matches the strings `"ad"`, `"abcd"`, `"efabcd"`, `"aaaad"`, and `"adddd"`.

C.2.13.3 Patterns Used for Filename Expansion

The caveat about a <slash> within a bracket expression is derived from historical practice. The pattern `"a[b/c]d"` does not match such pathnames as **abd** or **a/d**. On some implementations (including those conforming to the Single UNIX Specification), it matched a pathname of literally `"a[b/c]d"`. On other systems, it produced an undefined condition (an unescaped `'['` used outside a bracket expression). In this version, the XSI behavior is now required.

Filenames beginning with a <period> historically have been specially protected from view on UNIX systems. A proposal to allow an explicit <period> in a bracket expression to match a leading <period> was considered; it is allowed as an implementation extension, but a conforming application cannot make use of it. If this extension becomes popular in the future, it will be considered for a future version of the Shell and Utilities volume of POSIX.1-2017.

Historical systems have varied in their permissions requirements. To match **f*/bar** has required read permissions on the **f*** directories in the System V shell, but the Shell and Utilities volume of POSIX.1-2017, the C shell, and KornShell require only search permissions.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0043 [963] is applied.

C.2.14 Special Built-In Utilities

See the RATIONALE sections on the individual reference pages.

POSIX.1-2008, Technical Corrigendum 2, XCU/TC2-2008/0044 [882] and XCU/TC2-2008/0045 [654] are applied.

C.3 Batch Environment Services and Utilities

Scope of the Batch Environment Services and Utilities Option

This section summarizes the deliberations of the IEEE P1003.15 (Batch Environment) working group in the development of the Batch Environment Services and Utilities option, which covers a set of services and utilities defining a batch processing system.

This informative section contains historical information concerning the contents of the amendment and describes why features were included or discarded by the working group.

History of Batch Systems

The supercomputing technical committee began as a ``Birds Of a Feather'' (BOF) at the January 1987 Usenix meeting. There was enough general interest to form a supercomputing attachment to the /usr/group working groups. Several subgroups rapidly formed. Of those subgroups, the batch group was the most ambitious. The first early meetings were spent evaluating user needs and existing batch implementations.

To evaluate user needs, individuals from the supercomputing community came and presented their needs. Common requests were flexibility, interoperability, control of resources, and ease-of-use. Backward-compatibility was not an issue. The working group then evaluated some existing systems. The following different systems were evaluated:

PROD

Convex Distributed Batch

NQS

CTSS

MDQS from Ballistics Research Laboratory (BRL)

Finally, NQS was chosen as a model because it satisfied not only the most user requirements, but because it was public domain, already implemented on a variety of hardware platforms, and network-based.

Historical Implementations of Batch Systems

Deferred processing of work under the control of a scheduler has been a feature of most proprietary operating systems from the earliest days of multi-user systems in order to maximize utilization of the computer.

The arrival of UNIX systems proved to be a dilemma to many hardware providers and users because it did not include the sophisticated batch facilities offered by the proprietary systems. This omission was rectified in 1986 by NASA Ames Research Center who developed the Network Queuing System (NQS) as a portable UNIX application that allowed the routing and processing of batch ``jobs'' in a network. To encourage its usage, the product was later put into the public domain. It was promptly picked up by UNIX hardware providers, and ported and developed for their respective hardware and UNIX implementations.

Many major vendors, who traditionally offer a batch-dominated environment, ported the public-domain product to their systems, customized it to support the capabilities of their systems, and added many customer-requested features.

Due to the strong hardware provider and customer acceptance of NQS, it was decided to use NQS as the basis for the POSIX Batch Environment amendment in 1987. Other batch systems considered at the time included CTSS, MDQS (a forerunner of NQS from the Ballistics Research Laboratory), and PROD (a Los Alamos Labs development). None were thought to have both the functionality and acceptability of NQS.

128778 **NQS Differences from the at utility**

128779 The base standard *at* and *batch* utilities are not sufficient to meet the batch processing needs in a
128780 supercomputing environment and additional functionality in the areas of resource management,
128781 job scheduling, system management, and control of output is required.

128782 **Batch Environment Services and Utilities Option Definitions**

128783 The concept of a batch job is closely related to a session with a session leader. The main
128784 difference is that a batch job does not have a controlling terminal. There has been much debate
128785 over whether to use the term ``request'' or ``job''. Job was the final choice because of the
128786 historical use of this term in the batch environment.

128787 The current definition for job identifiers is not sufficient with the model of destinations. The
128788 current definition is:

128789 `sequence_number.originating_host`

128790 Using the model of destination, a host may include multiple batch nodes, the location of which
128791 is identified uniquely by a name or directory service. If the current definition is used, batch
128792 nodes running on the same host would have to coordinate their use of sequence numbers, as
128793 sequence numbers are assigned by the originating host. The alternative is to use the originating
128794 batch node name instead of the originating host name.

128795 The reasons for wishing to run more than one batch system per host could be the following.

128796 A test and production batch system are maintained on a single host. This is most likely in a
128797 development facility, but could also arise when a site is moving from one version to another. The
128798 new batch system could be installed as a test version that is completely separate from the
128799 production batch system, so that problems can be isolated to the test system. Requiring the batch
128800 nodes to coordinate their use of sequence numbers creates a dependency between the two
128801 nodes, and that defeats the purpose of running two nodes.

128802 A site has multiple departments using a single host, with different management policies. An
128803 example of contention might be in job selection algorithms. One group might want a FIFO type
128804 of selection, while another group wishes to use a more complex algorithm based on resource
128805 availability. Again, requiring the batch nodes to coordinate is an unnecessary binding.

128806 The proposal eventually accepted was to replace originating host with originating batch node.
128807 This supplies sufficient granularity to ensure unique job identifiers. If more than one batch node
128808 is on a particular host, they each have their own unique name.

128809 The queue portion of a destination is not part of the job identifier as these are not required to be
128810 unique between batch nodes. For instance, two batch nodes may both have queues called small,
128811 medium, and large. It is only the batch node name that is uniquely identifiable throughout the
128812 batch system. The queue name has no additional function in this context.

128813 Assume there are three batch nodes, each of which has its own name server. On batch node one,
128814 there are no queues. On batch node two, there are fifty queues. On batch node three, there are
128815 forty queues. The system administrator for batch node one does not have to configure queues,
128816 because there are none implemented. However, if a user wishes to send a job to either batch
128817 node two or three, the system administrator for batch node one must configure a destination
128818 that maps to the appropriate batch node and queue. If every queue is to be made accessible from
128819 batch node one, the system administrator has to configure ninety destinations.

128820 To avoid requiring this, there should be a mechanism to allow a user to separate the destination
128821 into a batch node name and a queue name. Then, an implementation that is configured to get to
128822 all the batch nodes does not need any more configuration to allow a user to get to all of the
128823 queues on all of the batch nodes. The node name is used to locate the batch node, while the

queue name is sent unchanged to that batch node.

The following are requirements that a destination identifier must be capable of providing:

The ability to direct a job to a queue in a particular batch node.

The ability to direct a job to a particular batch node.

The ability to group at a higher level than just one queue. This includes grouping similar queues across multiple batch nodes (this is a pipe queue).

The ability to group batch nodes. This allows a user to submit a job to a group name with no knowledge of the batch node configuration. This also provides aliasing as a special case. Aliasing is a group containing only one batch node name. The group name is the alias.

In addition, the administrator has the following requirements:

The ability to control access to the queues.

The ability to control access to the batch nodes.

The ability to control access to groups of queues (pipe queues).

The ability to configure retry time intervals and durations.

The requirements of the user are met by destination as explained in the following.

The user has the ability to specify a queue name, which is known only to the batch node specified. There is no configuration of these queues required on the submitting node.

The user has the ability to specify a batch node whose name is network-unique. The configuration required is that the batch node be defined as an application, just as other applications such as FTP are configured.

Once a job reaches a queue, it can again become a user of the batch system. The batch node can choose to send the job to another batch node or queue or both. In other words, the routing is at an application level, and it is up to the batch system to choose where the job will be sent. Configuration is up to the batch node where the queue resides. This provides grouping of queues across batch nodes or within a batch node. The user submits the job to a queue, which by definition routes the job to other queues or nodes or both.

A node name may be given to a naming service, which returns multiple addresses as opposed to just one. This provides grouping at a batch node level. This is a local issue, meaning that the batch node must choose only one of these addresses. The list of addresses is not sent with the job, and once the job is accepted on another node, there is no connection between the list and the job. The requirements of the administrator are met by destination as explained in the following.

The control of queues is a batch system issue, and will be done using the batch administrative utilities.

The control of nodes is a network issue, and will be done through whatever network facilities are available.

The control of access to groups of queues (pipe queues) is covered by the control of any other queue. The fact that the job may then be sent to another destination is not relevant.

The propagation of a job across more than one point-to-point connection was dropped because of its complexity and because all of the issues arising from this capability could not be resolved. It could be provided as additional functionality at some time in the future.

The addition of *network* as a defined term was done to clarify the difference between a network of batch nodes as opposed to a network of hosts. A network of batch nodes is referred to as a

128867 batch system. The network refers to the actual host configuration. A single host may have
128868 multiple batch nodes.

128869 In the absence of a standard network naming convention, this option establishes its own
128870 convention for the sake of consistency and expediency. This is subject to change, should a future
128871 working group develop a standard naming convention for network pathnames.

128872 C.3.1 Batch General Concepts

128873 During the development of the Batch Environment Services and Utilities option, a number of
128874 topics were discussed at length which influenced the wording of the normative text but could
128875 not be included in the final text. The following items are some of the most significant terms and
128876 concepts of those discussed:

128877 Small and Consistent Command Set

128878 Often, conventional utilities from UNIX systems have a very complicated utility syntax
128879 and usage. This can often result in confusion and errors when trying to use them. The
128880 Batch Environment Services and Utilities option utility set, on the other hand, has been
128881 paired to a small set of robust utilities with an orthogonal calling sequence.

128882 Checkpoint/Restart

128883 This feature permits an already executing process to checkpoint or save its contents. Some
128884 implementations permit this at both the batch utility level (for example, checkpointing this
128885 job upon its abnormal termination) or from within the job itself via a system call. Support
128886 of checkpoint/restart is optional. A conscious, careful effort was made to make the *qsub*
128887 utility consistently refer to checkpoint/restart as optional functionality.

128888 Rerunability

128889 When a user submits a job for batch processing, they can designate it ``rerunnable'' in that
128890 it will automatically resume execution from the start of the job if the machine on which it
128891 was executing crashes for some reason. The decision on whether the job will be rerun or
128892 not is entirely up to the submitter of the job and no decisions will be made within the batch
128893 system. A job that is rerunnable and has been submitted with the proper
128894 checkpoint/restart switch will first be checkpointed and execution begun from that point.
128895 Furthermore, use of the implementation-defined checkpoint/restart feature will not be
128896 defined in this context.

128897 Error Codes

128898 All utilities exit with error status zero (0) if successful, one (1) if a user error occurred, and
128899 two (2) for an internal Batch Environment Services and Utilities option error.

128900 Level of Portability

128901 Portability is specified at both the user, operator, and administrator levels. A conforming
128902 batch implementation prevents identical functionality and behavior at all these levels.
128903 Additionally, portable batch shell scripts with embedded Batch Environment Services and
128904 Utilities option utilities add an additional level of portability.

128905 Resource Specification

128906 A small set of globally understood resources, such as memory and CPU time, is specified.
128907 All conforming batch implementations are able to process them in a manner consistent
128908 with the yet-to-be-developed resource management model. Resources not in this
128909 amendment set are ignored and passed along as part of the argument stream of the utility.

Queue Position

Queue position is the place a job occupies in a queue. It is dependent on a variety of factors such as submission time and priority. Since priority may be affected by the implementation of fair share scheduling, the definition of queue position is implementation-defined.

Queue ID

A numerical queue ID is an external requirement for purposes of accounting. The identification number was chosen over queue name for processing convenience.

Job ID

A common notion of ``jobs'' is a collection of processes whose process group cannot be altered and is used for resource management and accounting. This concept is implementation-defined and, as such, has been omitted from the batch amendment.

Bytes *versus* Words

Except for one case, bytes are used as the standard unit for memory size. Furthermore, the definition of a word varies from machine to machine. Therefore, bytes will be the default unit of memory size.

Regular Expressions

The standard definition of regular expressions is much too broad to be used in the batch utility syntax. All that is needed is a simple concept of ``all''; for example, delete all my jobs from the named queue. For this reason, regular expressions have been eliminated from the batch amendment.

Display Privacy

How much data should be displayed locally through functions? Local policy dictates the amount of privacy. Library functions must be used to create and enforce local policy. Network and local *qstat*s must reflect the policy of the server machine.

Remote Host Naming Convention

It was decided that host names would be a maximum of 255 characters in length, with at most 15 characters being shown in displays. The 255 character limit was chosen because it is consistent with BSD. The 15-character limit was an arbitrary decision.

Network Administration

Network administration is important, but is outside the scope of the batch amendment. Network administration could be done with *rsh*. However, authentication becomes two-sided.

Network Administration Philosophy

Keep it simple. Centralized management should be possible. For example, Los Alamos needs a dumb set of CPUs to be managed by a central system *versus* several independently-managed systems as is the general case for the Batch Environment Services and Utilities option.

Operator Utility Defaults (that is, Default Host, User, Account, and so on)

It was decided that usability would override orthogonality and syntactic consistency.

The Batch System Manager and Operator Distinction

The distinction between manager and operator is that operators can only control the flow of jobs. A manager can alter the batch system configuration in addition to job flow. POSIX

makes a distinction between user and system administrator but goes no further. The concepts of manager and operator privileges fall under local policy. The distinction between manager and operator is historical in batch environments, and the Batch Environment Services and Utilities option has continued that distinction.

The Batch System Administrator

An administrator is equivalent to a batch system manager.

C.3.2 Batch Services

This rationale is provided as informative rather than normative text, to avoid placing requirements on implementors regarding the use of symbolic constants, but at the same time to give implementors a preferred practice for assigning values to these constants to promote interoperability.

The *Checkpoint* and *Minimum_Cpu_Interval* attributes induce a variety of behavior depending upon their values. Some jobs cannot or should not be checkpointed. Other users will simply need to ensure job continuation across planned downtimes; for example, scheduled preventive maintenance. For users consuming expensive resources, or for jobs that run longer than the mean time between failures, however, periodic checkpointing may be essential. However, system administrators must be able to set minimum checkpoint intervals on a queue-by-queue basis to guard against, for example, naive users specifying interval values too small on memory-intensive jobs. Otherwise, system overhead would adversely affect performance.

The use of symbolic constants, such as NO_CHECKPOINT, was introduced to lend a degree of formalism and portability to this option.

Support for checkpointing is optional for servers. However, clients must provide for the **−c** option, since in a distributed environment the job may run on a server that does provide such support, even if the host of the client does not support the checkpoint feature.

If the user does not specify the **−c** option, the default action is left unspecified by this option. Some implementations may wish to do checkpointing by default; others may wish to checkpoint only under an explicit request from the user.

The *Priority* attribute has been made non-optional. All clients already had been required to support the **−p** option. The concept of prioritization is common in historical implementations. The default priority is left to the server to establish.

The *Hold_Types* attribute has been modified to allow for implementation-defined hold types to be passed to a batch server.

It was the intent of the IEEE P1003.15 working group to mandate the support for the *Resource_List* attribute in this option by referring to another amendment, specifically the IEEE P1003.1a draft standard. However, during the development of the IEEE P1003.1a draft standard this was excluded. As such this requirement has been removed from the normative text.

The *Shell_Path* attribute has been modified to accept a list of shell paths that are associated with a host. The name of the attribute has been changed to *Shell_Path_List*.

C.3.3 Common Behavior for Batch Environment Utilities

This section was defined to meet the goal of a ``Small and Consistent Command Set'' for this option.

C.4 Utilities

For the utilities included in POSIX.1-2017, see the RATIONALE sections on the individual reference pages.

C.4.1 Utilities Removed in this Version

None.

C.4.2 Utilities Removed in the Previous Version

The following utilities were removed in the previous version of this standard:

calendar	*cu*	*line*	*pcat*	*unpack*
cancel	*dircmp*	*lint*	*pg*	*uulog*
cc	*dis*	*lpstat*	*spell*	*uuname*
col	*egrep*	*mail*	*sum*	*uupick*
cpio	*fgrep*	*pack*	*tar*	*uuto*

C.4.3 Exclusion of Utilities

The set of utilities contained in POSIX.1-2017 is drawn from the base documents for IEEE Std 1003.2-1992, with one addition: the *c99* utility. This section contains rationale for some of the deliberations that led to this set of utilities, and why certain utilities were excluded.

Many utilities were evaluated by the standard developers; more historical utilities were excluded from the base documents for IEEE Std 1003.2-1992 than included. The following list contains many common UNIX system utilities that were not included as mandatory utilities, in the User Portability Utilities option, in the XSI option, or in one of the software development groups. It is logistically difficult for this rationale to distribute correctly the reasons for not including a utility among the various utility options. Therefore, this section covers the reasons for all utilities not included in POSIX.1-2017.

This rationale is limited to a discussion of only those utilities actively or indirectly evaluated by the IEEE Std 1003.2-1992 standard developers, rather than the list of all known UNIX utilities from all its variants.

adb The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, many useful aspects of *adb* are very hardware-specific.

as Assemblers are hardware-specific and are included implicitly as part of the compilers in POSIX.1-2017.

banner The only known use of this command is as part of the *lp* printer header pages. It was decided that the format of the header is implementation-defined, so this utility is superfluous to application portability.

calendar This reminder service program is not useful to conforming applications.

cancel The *lp* (line printer spooling) system specified is the most basic possible and did not need this level of application control.

chroot This is primarily of administrative use, requiring superuser privileges.

col No utilities defined in POSIX.1-2017 produce output requiring such a filter. The *nroff* text formatter is present on many historical systems and will continue to remain as an extension; *col* is expected to be shipped by all the systems that ship *nroff*.

cpio This has been replaced by *pax*, for reasons explained in the rationale for that utility.

cpp This is subsumed by *c99*.

cu This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

dc The functionality of this utility can be provided by the *bc* utility; *bc* was selected because it was easier to use and had superior functionality. Although the historical versions of *bc* are implemented using *dc* as a base, POSIX.1-2017 prescribes the interface and not the underlying mechanism used to implement it.

dircmp Although a useful concept, the historical output of this directory comparison program is not suitable for processing in application programs. Also, the *diff* **−r** command gives equivalent functionality.

dis Disassemblers are hardware-specific.

emacs The community of *emacs* editing enthusiasts was adamant that the full *emacs* editor not be included in IEEE Std 1003.2-1992 because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to the standard, but lacking the extensibility required by the community. The author of the original *emacs* program also expressed his desire to omit the program. Furthermore, there were a number of historical UNIX systems that did not include *emacs*, or included it without supporting it, but there were very few that did not include and support *vi*.

ld This is subsumed by *c99*.

line The functionality of *line* can be provided with *read*.

lint This technology is partially subsumed by *c99*. It is also hard to specify the degree of checking for possible error conditions in programs in any compiler, and specifying what *lint* would do in these cases is equally difficult.

It is fairly easy to specify what a compiler does. It requires specifying the language, what it does with that language, and stating that the interpretation of any incorrect program is unspecified. Unfortunately, any description of *lint* is required to specify what to do with erroneous programs. Since the number of possible errors and questionable programming practices is infinite, one cannot require *lint* to detect all errors of any given class.

Additionally, some vendors complained that since many compilers are distributed in a binary form without a *lint* facility (because the ISO C standard does not require one), implementing the standard as a stand-alone product will be much

harder. Rather than being able to build upon a standard compiler component (simply by providing *c99* as an interface), source to that compiler would most likely need to be modified to provide the *lint* functionality. This was considered a major burden on system providers for a very small gain to developers (users).

login This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

lorder This utility is an aid in creating an implementation-defined detail of object libraries that the standard developers did not feel required standardization.

lpstat The *lp* system specified is the most basic possible and did not need this level of application control.

mail This utility was omitted in favor of *mailx* because there was a considerable functionality overlap between the two.

mknod This was omitted in favor of *mkfifo*, as *mknod* has too many implementation-defined functions.

news This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

pack This compression program was considered inferior to *compress*.

passwd This utility was proposed in an early draft of the IEEE Std 1003.2-1992 UPE but met with too many objections to be included. There were various reasons:

> Changing a password should not be viewed as a command, but as part of the login sequence. Changing a password should only be done while a trusted path is in effect.
>
> Even though the text in early drafts was intended to allow a variety of implementations to conform, the security policy for one site may differ from another site running with identical hardware and software. One site might use password authentication while the other did not. Vendors could not supply a *passwd* utility that would conform to POSIX.1-2017 for all sites using their system.
>
> This is really a subject for a system administration working group or a security working group.

pcat This compression program was considered inferior to *zcat*.

pg This duplicated many of the features of the *more* pager, which was preferred by the standard developers.

prof The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.

RCS RCS was originally considered as part of a version control utilities portion of the scope. However, this aspect was abandoned by the standard developers. SCCS is now included as an optional part of the XSI option.

red Restricted editor. This was not considered by the standard developers because it never provided the level of security restriction required.

rsh Restricted shell. This was not considered by the standard developers because it does not provide the level of security restriction that is implied by historical documentation.

sdb The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, some useful aspects of *sdb* are very hardware-specific.

sdiff The ``side-by-side *diff*'' utility from System V was omitted because it is used infrequently, and even less so by conforming applications. Despite being in System V, it is not in the SVID or XPG.

shar Any of the numerous ``shell archivers'' were excluded because they did not meet the requirement of existing practice.

shl This utility is terminal-oriented and is not useful from shell scripts or typical application programs. The job control aspects of the shell command language are generally more useful.

size The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.

spell This utility is not useful from shell scripts or typical application programs. The *spell* utility was considered, but was omitted because there is no known technology that can be used to make it recognize general language for user-specified input without providing a complete dictionary along with the input file.

su This utility is not useful from shell scripts or typical application programs. (There was also sentiment to avoid security-related utilities.)

sum This utility was renamed *cksum*.

tar This has been replaced by *pax*, for reasons explained in the rationale for that utility.

unpack This compression program was considered inferior to *uncompress*.

wall This utility is terminal-oriented and is not useful in shell scripts or typical applications. It is generally used only by system administrators.

Rationale (Informative)

Part D:

Portability Considerations

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

129146 *Appendix D*

129147 # *Portability Considerations (Informative)*

129148 This section contains information to satisfy various international requirements:

129149 Section D.1 describes perceived user requirements.

129150 Section D.2 (on page 3767) indicates how the facilities of POSIX.1-2017 satisfy those
129151 requirements.

129152 Section D.3 (on page 3775) offers guidance to writers of profiles on how the configurable
129153 options, limits, and optional behavior of POSIX.1-2017 should be cited in profiles.

129154 ## D.1 User Requirements

129155 This section describes the user requirements that were perceived by the standard developers.
129156 The primary source for these requirements was an analysis of historical practice in widespread
129157 use, as typified by the base documents for the ISO POSIX-1: 1996 standard.

129158 POSIX.1-2017 addresses the needs of users requiring open systems solutions for source code
129159 portability of applications. It currently addresses users requiring open systems solutions for
129160 source-code portability of applications involving multi-programming and process management
129161 (creating processes, signaling, and so on); access to files and directories in a hierarchy of file
129162 systems (opening, reading, writing, deleting files, and so on); access to asynchronous
129163 communications ports and other special devices; access to information about other users of the
129164 system; facilities supporting applications requiring bounded (realtime) response.

129165 The following users are identified for POSIX.1-2017:

129166 Those employing applications written in high-level languages, such as C, Ada, or
129167 FORTRAN.

129168 Users who desire conforming applications that do not necessarily require the
129169 characteristics of high-level languages (for example, the speed of execution of compiled
129170 languages or the relative security of source code intellectual property inherent in the
129171 compilation process).

129172 Users who desire conforming applications that can be developed quickly and can be
129173 modified readily without the use of compilers and other system components that may be
129174 unavailable on small systems or those without special application development
129175 capabilities.

129176 Users who interact with a system to achieve general-purpose time-sharing capabilities
129177 common to most business or government offices or academic environments: editing, filing,
129178 inter-user communications, printing, and so on.

129179 Users who develop applications for POSIX-conformant systems.

129180 Users who develop applications for UNIX systems.

129181 An acknowledged restriction on applicable users is that they are limited to the group of
129182 individuals who are familiar with the style of interaction characteristic of historically-derived
129183 systems based on one of the UNIX operating systems (as opposed to other historical systems

with different models, such as MS/DOS, Macintosh, VMS, MVS, and so on). Typical users would include program developers, engineers, or general-purpose time-sharing users.

The requirements of users of POSIX.1-2017 can be summarized as a single goal: *application source portability*. The requirements of the user are stated in terms of the requirements of portability of applications. This in turn becomes a requirement for a standardized set of syntax and semantics for operations commonly found on many operating systems.

The following sections list the perceived requirements for application portability.

D.1.1 Configuration Interrogation

An application must be able to determine whether and how certain optional features are provided and to identify the system upon which it is running, so that it may appropriately adapt to its environment.

Applications must have sufficient information to adapt to varying behaviors of the system.

D.1.2 Process Management

An application must be able to manage itself, either as a single process or as multiple processes. Applications must be able to manage other processes when appropriate.

Applications must be able to identify, control, create, and delete processes, and there must be communication of information between processes and to and from the system.

Applications must be able to use multiple flows of control with a process (threads) and synchronize operations between these flows of control.

D.1.3 Access to Data

Applications must be able to operate on the data stored on the system, access it, and transmit it to other applications. Information must have protection from unauthorized or accidental access or modification.

D.1.4 Access to the Environment

Applications must be able to access the external environment to communicate their input and results.

D.1.5 Access to Determinism and Performance Enhancements

Applications must have sufficient control of resource allocation to ensure the timeliness of interactions with external objects.

D.1.6 Operating System-Dependent Profile

The capabilities of the operating system may make certain optional characteristics of the base language in effect no longer optional, and this should be specified.

D.1.7 I/O Interaction

The interaction between the C language I/O subsystem (*stdio*) and the I/O subsystem of POSIX.1-2017 must be specified.

D.1.8 Internationalization Interaction

The effects of the environment of POSIX.1-2017 on the internationalization facilities of the C language must be specified.

D.1.9 C-Language Extensions

Certain functions in the C language must be extended to support the additional capabilities provided by POSIX.1-2017.

D.1.10 Command Language

Users should be able to define procedures that combine simple tools and/or applications into higher-level components that perform to the specific needs of the user. The user should be able to store, recall, use, and modify these procedures. These procedures should employ a powerful command language that is used for recurring tasks in conforming applications (scripts) in the same way that it is used interactively to accomplish one-time tasks. The language and the utilities that it uses must be consistent between systems to reduce errors and retraining.

D.1.11 Interactive Facilities

Use the system to accomplish individual tasks at an interactive terminal. The interface should be consistent, intuitive, and offer usability enhancements to increase the productivity of terminal users, reduce errors, and minimize retraining costs. Online documentation or usage assistance should be available.

D.1.12 Accomplish Multiple Tasks Simultaneously

Access applications and interactive facilities from a single terminal without requiring serial execution: switch between multiple interactive tasks; schedule one-time or periodic background work; display the status of all work in progress or scheduled; influence the priority scheduling of work, when authorized.

D.1.13 Complex Data Manipulation

Manipulate data in files in complex ways: sort, merge, compare, translate, edit, format, pattern match, select subsets (strings, columns, fields, rows, and so on). These facilities should be available to both conforming applications and interactive users.

D.1.14 File Hierarchy Manipulation

Create, delete, move/rename, copy, backup/archive, and display files and directories. These facilities should be available to both conforming applications and interactive users.

D.1.15 Locale Configuration

Customize applications and interactive sessions for the cultural and language conventions of the user. Employ a wide variety of standard character encodings. These facilities should be available to both conforming applications and interactive users.

D.1.16 Inter-User Communication

Send messages or transfer files to other users on the same system or other systems on a network. These facilities should be available to both conforming applications and interactive users.

D.1.17 System Environment

Display information about the status of the system (activities of users and their interactive and background work, file system utilization, system time, configuration, and presence of optional facilities) and the environment of the user (terminal characteristics, and so on). Inform the system operator/administrator of problems. Control access to user files and other resources.

D.1.18 Printing

Output files on a variety of output device classes, accessing devices on local or network-connected systems. Control (or influence) the formatting, priority scheduling, and output distribution of work. These facilities should be available to both conforming applications and interactive users.

D.1.19 Software Development

Develop (create and manage source files, compile/interpret, debug) portable open systems applications and package them for distribution to, and updating of, other systems.

D.2 Portability Capabilities

This section describes the significant portability capabilities of POSIX.1-2017 and indicates how the user requirements listed in Section D.1 (on page 3763) are addressed. The capabilities are listed in the same format as the preceding user requirements; they are summarized below:

Configuration Interrogation

Process Management

Access to Data

Access to the Environment

Access to Determinism and Performance Enhancements

Operating System-Dependent Profile

I/O Interaction

Internationalization Interaction

C-Language Extensions

Command Language

Interactive Facilities

Software Development

D.2.1 Configuration Interrogation

The *uname*( ) operation provides basic identification of the system. The *sysconf*( ), *pathconf*( ), and *fpathconf*( ) functions and the *getconf* utility provide means to interrogate the implementation to determine how to adapt to the environment in which it is running. These values can be either static (indicating that all instances of the implementation have the same value) or dynamic (indicating that different instances of the implementation have the different values, or that the value may vary for other reasons, such as reconfiguration).

Unsatisfied Requirements

None directly. However, as new areas are added, there will be a need for additional capability in this area.

D.2.2 Process Management

The *fork*(), *exec* family, *posix_spawn*(), and *posix_spawnp*() functions provide for the creation of new processes or the insertion of new applications into existing processes. The *_Exit*(), *_exit*(), *exit*(), and *abort*() functions allow for the termination of a process by itself. The *wait*(), *waitid*(), and *waitpid*() functions allow one process to deal with the termination of another.

The *times*() function allows for basic measurement of times used by a process. Various functions, including *fstat*(), *getegid*(), *geteuid*(), *getgid*(), *getgrgid*(), *getgrnam*(), *getlogin*(), *getpid*(), *getppid*(), *getpwnam*(), *getpwuid*(), *getuid*(), *lstat*(), and *stat*(), provide for access to the identifiers of processes and the identifiers and names of owners of processes (and files).

The various functions operating on environment variables provide for communication of information (primarily user-configurable defaults) from a parent to child processes.

The operations on the current working directory control and interrogate the directory from which relative pathname searches start. The *umask*() function controls the default protections applied to files created by the process.

The *alarm*(), *pause*(), *sleep*(), *ualarm*(), and *usleep*() operations allow the process to suspend until a timer has expired or to be notified when a period of time has elapsed. The *time*() operation interrogates the current time and date.

The signal mechanism provides for communication of events either from other processes or from the environment to the application, and the means for the application to control the effect of these events. The mechanism provides for external termination of a process and for a process to suspend until an event occurs. The mechanism also provides for a value to be associated with an event.

Job control provides a means to group processes and control them as groups, and to control their access to the function between the user and the system (the ``controlling terminal''). It also provides the means to suspend and resume processes.

The Process Scheduling option provides control of the scheduling and priority of a process.

The Message Passing option provides a means for interprocess communication involving small amounts of data.

The Memory Management facilities provide control of memory resources and for the sharing of memory. This functionality is mandatory on POSIX-conforming systems.

The Threads facilities provide multiple flows of control with a process (threads), synchronization between threads (including mutexes, barriers, and spin locks), association of data with threads, and controlled cancellation of threads.

The XSI interprocess communications functionality provide an alternate set of facilities to manipulate semaphores, message queues, and shared memory. These are provided on XSI-conformant systems to support conforming applications developed to run on UNIX systems.

D.2.3 Access to Data

The *open*(), *close*(), *fclose*(), *fopen*(), and *pipe*() functions provide for access to files and data. Such files may be regular files, interprocess data channels (pipes), or devices. Additional types of objects in the file system are permitted and are being contemplated for standardization.

The *access*(), *chmod*(), *chown*(), *dup*(), *dup2*(), *fchmod*(), *fcntl*(), *fstat*(), *ftruncate*(), *lstat*(), *readlink*(), *realpath*(), *stat*(), and *utime*() functions allow for control and interrogation of file and file-related objects (including symbolic links), and their ownership, protections, and timestamps.

The *fgetc*( ), *fputc*( ), *fread*( ), *fseek*( ), *fsetpos*( ), *fwrite*( ), *getc*( ), *getchar*( ), *lseek*( ), *putchar*( ), *putc*( ), *read*( ), and *write*( ) functions provide for data transfer from the application to files (in all their forms).

The *closedir*( ), *link*( ), *mkdir*( ), *opendir*( ), *readdir*( ), *rename*( ), *rmdir*( ), *rewinddir*( ), and *unlink*( ) functions provide for a complete set of operations on directories. Directories can arbitrarily contain other directories, and a single file can be mentioned in more than one directory.

The *faccessat*( ), *openat*( ), *fchmodat*( ), *fchownat*( ), *fstatat*( ), *linkat*( ) *renameat*( ), *readlinkat*( ), *sylimkat*( ), and *unlinkat*( ) functions allow for race-free and thread-safe file access. The motivation for the introduction of these functions was as follows:

> Interfaces taking a pathname may be limited by the maximum length of a pathname ({PATH_MAX}). The absolute path of files can far exceed this length. The alternative solution of changing the working directory and using relative pathnames is not thread-safe.
>
> A second motivation is that files accessed outside the current working directory are subject to attacks caused by the race condition created by changing any of the elements of the pathnames used.
>
> A third motivation is to allow application code which makes use of a virtual current working directory for each individual thread. In the alternative model there is only one current working directory for all threads.

The file-locking mechanism provides for advisory locking (protection during transactions) of ranges of bytes (in effect, records) in a file.

The *confstr*( ), *fpathconf*( ), *pathconf*( ), and *sysconf*( ) functions provide for enquiry as to the behavior of the system where variability is permitted.

The asynchronous input and output functions *aio_cancel*( ), *aio_error*( ), *aio_fsync*( ), *aio_read*( ), *aio_return*( ), *aio_suspend*( ), *aio_write*( ), and *lio_listio*( ) provide for initiation and control of asynchronous data transfers.

The Synchronized Input and Output option provides for assured commitment of data to media.

D.2.4 Access to the Environment

The operations and types in XBD are provided for access to asynchronous serial devices. The primary intended use for these is the controlling terminal for the application (the interaction point between the user and the system). They are general enough to be used to control any asynchronous serial device. The functions are also general enough to be used with many other device types as a user interface when some emulation is provided.

Less detailed access is provided for other device types, but in many instances an application need not know whether an object in the file system is a device or a regular file to operate correctly.

Unsatisfied Requirements

Detailed control of common device classes, specifically magnetic tape, is not provided.

D.2.5 Bounded (Realtime) Response

The realtime signal functions *sigqueue*( ), *sigtimedwait*( ), and *sigwaitinfo*( ) provide queued signals and the prioritization of the handling of signals.

The SCHED_FIFO, SCHED_SPORADIC, and SCHED_RR scheduling policies provide control over processor allocation.

The semaphore functions *sem_close*( ), *sem_destroy*( ), *sem_getvalue*( ), *sem_init*( ), *sem_open*( ), *sem_post*( ), *sem_timedwait*( ), *sem_trywait*( ), *sem_unlink*( ), and *sem_wait*( ) provide high-performance synchronization.

The memory management functions provide memory locking for control of memory allocation, file mapping for high performance, and shared memory for high-performance interprocess communication. The Message Passing option provides for interprocess communication without being dependent on shared memory.

The timers functions *clock_getres*( ), *clock_gettime*( ), *clock_settime*( ), *nanosleep*( ), *timer_create*( ), *timer_delete*( ), *timer_getoverrun*( ), *timer_gettime*( ), and *timer_settime*( ) provide functionality to manipulate clocks and timers and include a high resolution function called *nanosleep*( ) with a finer resolution than the *sleep*( ) function.

The timeout functions ‡' *pthread_mutex_timedlock*( ), *pthread_rwlock_timedrdlock*( ), *pthread_rwlock_timedwrlock*( ), and *sem_timedwait*( ) ‡the Typed Memory Objects option and the Monotonic Clock option provide further facilities for applications to use to obtain predictable bounded response.

D.2.6 Operating System-Dependent Profile

POSIX.1-2017 makes no distinction between text and binary files. The values of EXIT_SUCCESS and EXIT_FAILURE are further defined.

Unsatisfied Requirements

None known, but the ISO C standard may contain some additional options that could be specified.

D.2.7 I/O Interaction

POSIX.1-2017 defines how each of the ISO C standard *stdio* functions interact with the POSIX.1 operations, typically specifying the behavior in terms of POSIX.1 operations.

Unsatisfied Requirements

None.

D.2.8 Internationalization Interaction

The POSIX.1-2017 environment operations provide a means to define the environment for *setlocale*( ) and time functions such as *ctime*( ). The *tzset*( ) function is provided to set time conversion information.

The *nl_langinfo*( ) function is provided to query locale-specific cultural settings.

The multiple concurrent locale functions *duplocale*( ), *freelocale*( ), *is***_l*( ), *newlocale*( ), *strcasecmp_l*( ), *strcoll_l*( ), *strfmon_l*( ), *strncasecmp_l*( ), *strxfrm_l*( ), *tolower_l*( ), *toupper_l*( ), *towctrans_l*( ), *towlower*( ), *towupper*( ), *uselocale*( ), *wcscasecmp_l*( ), *wcscoll_l*( ), *wcsncasecmp_l*( ), *wcsxfrm_l*( ), *wctrans_l*( ), and *wctype_l*( ) are provide to support per-thread locale information.

Unsatisfied Requirements

None.

D.2.9 C-Language Extensions

The *setjmp*( ) and *longjmp*( ) functions are not defined to be cognizant of the signal masks defined for POSIX.1. The *sigsetjmp*( ) and *siglongjmp*( ) functions are provided to fill this gap.

The *_setjmp*( ) and *_longjmp*( ) functions are provided as XSI options to support historic practice.

Unsatisfied Requirements

None.

D.2.10 Command Language

The shell command language, as described in XCU Chapter 2 (on page 2345), is a common language useful in batch scripts, through an API to high-level languages (for the C-Language Binding option, *system*( ) and *popen*( )) and through an interactive terminal (see the *sh* utility). The shell language has many of the characteristics of a high-level language, but it has been designed to be more suitable for user terminal entry and includes interactive debugging facilities. Through the use of pipelining, many complex commands can be constructed from combinations of data filters and other common components. Shell scripts can be created, stored, recalled, and modified by the user with simple editors.

In addition to the basic shell language, the following utilities offer features that simplify and enhance programmatic access to the utilities and provide features normally found only in high-level languages: *basename*, *bc*, *command*, *dirname*, *echo*, *env*, *expr*, *false*, *printf*, *read*, *sleep*, *tee*, *test*, *time**,[9] *true*, *wait*, *xargs*, and all of the special built-in utilities in XCU Section 2.14 (on page 2384).

---

9. The utilities listed with an asterisk here and later in this section are present only on systems which support the User Portability Utilities option. There may be further restrictions on the utilities offered with various configuration option combinations; see the individual utility descriptions.

129447 **Unsatisfied Requirements**

129448 None.

129449 D.2.11 Interactive Facilities

129450 The utilities offer a common style of command-line interface through conformance to the Utility
129451 Syntax Guidelines (see XBD Section 12.2, on page 216) and the common utility defaults (see XCU
129452 Section 1.4, on page 2336). The *sh* utility offers an interactive command-line history and editing
129453 facility.

129454 The following utilities can be used interactively as well as by scripts; *alias*, *fc*, *mailx*, *unalias*, and
129455 *write*.

129456 The following utilities in the User Portability Utilities option provide for interactive use: *ex*, *more*,
129457 and *vi*; the *man* utility offers online access to system documentation.

129458 **Unsatisfied Requirements**

129459 The command line interface to individual utilities is as intuitive and consistent as historical
129460 practice allows. Work underway based on graphical user interfaces may be more suitable for
129461 novice or occasional users of the system.

129462 D.2.12 Accomplish Multiple Tasks Simultaneously

129463 The shell command language offers background processing through the asynchronous list
129464 command form; see XCU Section 2.9 (on page 2365).

129465 The *nohup* utility makes background processing more robust and usable.

129466 The *kill* utility can terminate background jobs.

129467 The following utilities support periodic job scheduling, control, and display: *at*, *batch*, *crontab*,
129468 *nice*, *ps*, and *renice*.

129469 When the User Portability Utilities option is supported, the following utilities allow
129470 manipulation of jobs: *bg*, *fg*, and *jobs*.

129471 **Unsatisfied Requirements**

129472 Terminals with multiple windows may be more suitable for some multi-tasking interactive uses
129473 than the job control approach in POSIX.1-2017. See the comments on graphical user interfaces in
129474 Section D.2.11. The *nice* and *renice* utilities do not necessarily take advantage of complex system
129475 scheduling algorithms that are supported by the realtime options within POSIX.1-2017.

129476 D.2.13 Complex Data Manipulation

129477 The following utilities address user requirements in this area: *asa*, *awk*, *bc*, *cmp*, *comm*, *csplit*, *cut*,
129478 *dd*, *diff*, *ed*, *ex**, *expand*, *expr*, *find*, *fold*, *grep*, *head*, *join*, *od*, *paste*, *pr*, *printf*, *sed*, *sort*, *split*, *tabs*, *tail*, *tr*,
129479 *unexpand*, *uniq*, *uudecode*, *uuencode*, and *wc*.

Unsatisfied Requirements

Sophisticated text formatting utilities, such as *troff* or *TeX*, are not included. Standards work in the area of SGML may satisfy this.

D.2.14 File Hierarchy Manipulation

The following utilities address user requirements in this area: *basename*, *cd*, *chgrp*, *chmod*, *chown*, *cksum*, *cp*, *dd*, *df*, *diff*, *dirname*, *du*, *find*, *ls*, *ln*, *mkdir*, *mkfifo*, *mv*, *patch*, *pathchk*, *pax*, *pwd*, *rm*, *rmdir*, *test*, and *touch*.

Unsatisfied Requirements

Some graphical user interfaces offer more intuitive file manager components that allow file manipulation through the use of icons for novice users.

D.2.15 Locale Configuration

The standard utilities are affected by the various *LC_* variables to achieve locale-dependent operation: character classification, collation sequences, regular expressions and shell pattern matching, date and time formats, numeric formatting, and monetary formatting. When the POSIX2_LOCALEDEF option is supported, applications can provide their own locale definition files.

The following utilities address user requirements in this area: *date*, *ed*, *ex**, *find*, *grep*, *locale*, *localedef*, *more**, *sed*, *sh*, *sort*, *tr*, *uniq*, and *vi**.

The *iconv*(), *iconv_close*(), and *iconv_open*() functions are available to allow an application to convert character data between supported character sets.

The *gencat* utility and the *catopen*(), *catclose*(), and *catgets*() functions provide for message catalog manipulation.

Unsatisfied Requirements

Some aspects of multi-byte character and state-encoded character encodings have not yet been addressed. The C-language functions, such as *getopt*(), are generally limited to single-byte characters. The effect of the *LC_MESSAGES* variable on message formats is only suggested at this time.

D.2.16 Inter-User Communication

The following utilities address user requirements in this area: *cksum*, *mailx*, *mesg*, *patch*, *pax*, *talk*, *uudecode*, *uuencode*, *who*, and *write*.

The historical UUCP utilities are included as a separate UUCP Utilities option.

Unsatisfied Requirements

None.

D.2.17 System Environment

The following utilities address user requirements in this area: *chgrp*, *chmod*, *chown*, *df*, *du*, *env*, *getconf*, *id*, *logger*, *logname*, *mesg*, *newgrp*, *ps*, *stty*, *tput*, *tty*, *umask*, *uname*, and *who*.

The *closelog*( ), *openlog*( ), *setlogmask*( ), and *syslog*( ) functions provide system logging facilities on XSI-conformant systems; these are analogous to the *logger* utility.

Unsatisfied Requirements

None.

D.2.18 Printing

The following utilities address user requirements in this area: *pr* and *lp*.

Unsatisfied Requirements

There are no features to control the formatting or scheduling of the print jobs.

D.2.19 Software Development

The following utilities address user requirements in this area: *ar*, *asa*, *awk*, *c99*, *ctags*, *fort77*, *getconf*, *getopts*, *lex*, *localedef*, *make*, *nm*, *od*, *patch*, *pax*, *strings*, *strip*, *time*, and *yacc*.

The *system*( ), *popen*( ), *pclose*( ), *regcomp*( ), *regexec*( ), *regerror*( ), *regfree*( ), *fnmatch*( ), *getopt*( ), *glob*( ), *globfree*( ), *wordexp*( ), and *wordfree*( ) functions allow C-language programmers to access some of the interfaces used by the utilities, such as argument processing, regular expressions, and pattern matching.

The SCCS source-code control system utilities are available on systems supporting the XSI Development option.

Unsatisfied Requirements

There are no language-specific development tools related to languages other than C and FORTRAN. The C tools are more complete and varied than the FORTRAN tools. There is no data dictionary or other CASE-like development tools.

D.2.20 Future Growth

It is arguable whether or not all functionality to support applications is potentially within the scope of POSIX.1-2017. As a simple matter of practicality, it cannot be. Areas such as graphics, application domain-specific functionality, windowing, and so on, should be in unique standards. As such, they are properly ``Unsatisfied Requirements'' in terms of providing fully conforming applications, but ones which are outside the scope of POSIX.1-2017.

However, as the standards evolve, certain functionality once considered ``exotic'' enough to be part of a separate standard become common enough to be included in a core standard such as this. Realtime and networking, for example, have both moved from separate standards (with

much difficult cross-referencing) into this standard over time, and although no specific areas have been identified for inclusion in a future version, such inclusions seem likely.

D.3 Profiling Considerations

This section offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of POSIX.1-2017 should be cited in profiles. Profile writers should consult the general guidance in POSIX.0 when writing POSIX Standardized Profiles.

The information in this section is an inclusive list of features that should be considered by profile writers. Subsetting of POSIX.1-2017 should follow XBD Section 2.1.5.1 (on page 21). A set of profiling options is described in Appendix E (on page 3789).

D.3.1 Configuration Options

There are two set of options suggested by POSIX.1-2017: those for POSIX-conforming systems and those for X/Open System Interface (XSI) conformance. The requirements for XSI conformance are documented in the Base Definitions volume of POSIX.1-2017 and not discussed further here, as they superset the POSIX conformance requirements.

D.3.2 Configuration Options (Shell and Utilities)

There are three broad optional configurations for the Shell and Utilities volume of POSIX.1-2017: basic execution system, development system, and user portability interactive system. The options to support these, and other minor configuration options, are listed in XBD Chapter 2 (on page 15). Profile writers should consult the following list and the comments concerning user requirements addressed by various components in Section D.2 (on page 3767).

POSIX2_UPE

The system supports the User Portability Utilities option.

This option is a requirement for a user portability interactive system. It is required frequently except for those systems, such as embedded realtime or dedicated application systems, that support little or no interactive time-sharing work by users or operators. XSI-conformant systems support this option.

POSIX2_SW_DEV

The system supports the Software Development Utilities option.

This option is required by many systems, even those in which actual software development does not occur. The *make* utility, in particular, is required by many application software packages as they are installed onto the system. If POSIX2_C_DEV is supported, POSIX2_SW_DEV is almost a mandatory requirement because of *ar* and *make*.

POSIX2_C_BIND

The system supports the C-Language Bindings option.

This option is required on some implementations developing complex C applications or on any system installing C applications in source form that require the functions in this option. The *system*() and *popen*() functions, in particular, are widely used by applications; the others are rather more specialized.

129584 POSIX2_C_DEV
129585 The system supports the C-Language Development Utilities option.

129586 This option is required by many systems, even those in which actual C-language software
129587 development does not occur. The *c99* utility, in particular, is required by many application
129588 software packages as they are installed onto the system. The *lex* and *yacc* utilities are used
129589 less frequently.

129590 POSIX2_FORT_DEV
129591 The system supports the FORTRAN Development Utilities option

129592 As with C, this option is needed on any system developing or installing FORTRAN
129593 applications in source form.

129594 POSIX2_FORT_RUN
129595 The system supports the FORTRAN Runtime Utilities option.

129596 This option is required for some FORTRAN applications that need the *asa* utility to convert
129597 Hollerith printing statement output. It is unknown how frequently this occurs.

129598 POSIX2_LOCALEDEF
129599 The system supports the creation of locales.

129600 This option is needed if applications require their own customized locale definitions to
129601 operate. It is presently unknown whether many applications are dependent on this.
129602 However, the option is virtually mandatory for systems in which internationalized
129603 applications are developed.

129604 XSI-conformant systems support this option.

129605 POSIX2_PBS
129606 The system supports the Batch Environment Services and Utilities option.

129607 POSIX2_PBS_ACCOUNTING
129608 The system supports the optional feature of accounting within the Batch Environment
129609 Services and Utilities option. It will be required in servers that implement the optional
129610 feature of accounting.

129611 POSIX2_PBS_CHECKPOINT
129612 The system supports the optional feature of checkpoint/restart within the Batch
129613 Environment Services and Utilities option.

129614 POSIX2_PBS_LOCATE
129615 The system supports the optional feature of locating batch jobs within the Batch
129616 Environment Services and Utilities option.

129617 POSIX2_PBS_MESSAGE
129618 The system supports the optional feature of sending messages to batch jobs within the Batch
129619 Environment Services and Utilities option.

129620 POSIX2_PBS_TRACK
129621 The system supports the optional feature of tracking batch jobs within the Batch
129622 Environment Services and Utilities option.

129623 POSIX2_CHAR_TERM
129624 The system supports at least one terminal type capable of all operations described in
129625 POSIX.1-2017.

129626 On systems with POSIX2_UPE, this option is almost always required. It was developed
129627 solely to allow certain specialized vendors and user applications to bypass the requirement
129628 for general-purpose asynchronous terminal support. For example, an application and

129629 system that was suitable for block-mode terminals, such as IBM 3270s, would not need this
129630 option.

129631 XSI-conformant systems support this option.

129632 D.3.3 Configurable Limits

129633 Very few of the limits need to be increased for profiles. No profile can cite lower values.

129634 {POSIX2_BC_BASE_MAX}
129635 {POSIX2_BC_DIM_MAX}
129636 {POSIX2_BC_SCALE_MAX}
129637 {POSIX2_BC_STRING_MAX}
129638 No increase is anticipated for any of these *bc* values, except for very specialized applications
129639 involving huge numbers.

129640 {POSIX2_COLL_WEIGHTS_MAX}
129641 Some natural languages with complex collation requirements require an increase from the
129642 default 2 to 4; no higher numbers are anticipated.

129643 {POSIX2_EXPR_NEST_MAX}
129644 No increase is anticipated.

129645 {POSIX2_LINE_MAX}
129646 This number is much larger than most historical applications have been able to use. At some
129647 future time, applications may be rewritten to take advantage of even larger values.

129648 {POSIX2_RE_DUP_MAX}
129649 No increase is anticipated.

129650 {POSIX2_VERSION}
129651 This is actually not a limit, but a standard version stamp. Generally, a profile should specify
129652 XCU Chapter 2 (on page 2345) by name in the normative references section, not this value.

129653 D.3.4 Configuration Options (System Interfaces)

129654 {NGROUPS_MAX}
129655 A non-zero value indicates that the implementation supports supplementary groups.

129656 This option is needed where there is a large amount of shared use of files, but where a
129657 certain amount of protection is needed. Many profiles[10] are known to require this option; it
129658 should only be required if needed, but it should never be prohibited.

129659 _POSIX_ADVISORY_INFO
129660 The system provides advisory information for file management.

129661 This option allows the application to specify advisory information that can be used to
129662 achieve better or even deterministic response time in file manager or input and output
129663 operations.

129664 _POSIX_ASYNCHRONOUS_IO
129665 Support for asynchronous input and output is mandatory in POSIX.1-2017.

129666 10. There are no formally approved profiles of POSIX.1-2017 at the time of publication; the reference here is to various profiles generated by
129667 private bodies or governments.

129668 _POSIX_BARRIERS
129669 Support for barrier synchronization is mandatory in POSIX.1-2017.

129670 This facility allows efficient synchronization of multiple parallel threads in multi-processor
129671 systems in which the operation is supported in part by the hardware architecture.

129672 _POSIX_CHOWN_RESTRICTED
129673 The system restricts the right to ``give away'' files to other users. It is mandatory that an
129674 implementation be able to support this facility in POSIX.1-2017; however, it is recognized
129675 that implementations need not enable the functionality by default.

129676 Some applications expect that they can change the ownership of files in this way. It is
129677 provided where either security or system account requirements cause this ability to be a
129678 problem. It is also known to be specified in many profiles.

129679 _POSIX_CLOCK_SELECTION
129680 Support for clock selection is mandatory in POSIX.1-2017.

129681 This facility allows applications to request a high resolution sleep in order to suspend a
129682 thread during a relative time interval, or until an absolute time value, using the desired
129683 clock. It also allows the application to select the clock used in a *pthread_cond_timedwait*()
129684 function call.

129685 _POSIX_CPUTIME
129686 The system supports the Process CPU-Time Clocks option.

129687 This option allows applications to use a new clock that measures the execution times of
129688 processes or threads, and the possibility to create timers based upon these clocks, for
129689 runtime detection (and treatment) of execution time overruns.

129690 _POSIX_FSYNC
129691 The system supports file synchronization requests.

129692 This option was created to support historical systems that did not provide the feature.
129693 Applications that are expecting guaranteed completion of their input and output operations
129694 should require the _POSIX_SYNC_IO option. This option should never be prohibited.

129695 XSI-conformant systems support this option.

129696 _POSIX_IPV6
129697 The system supports facilities related to Internet Protocol Version 6 (IPv6).

129698 This option was created to allow systems to transition to IPv6.

129699 _POSIX_JOB_CONTROL
129700 Support for job control is mandatory in POSIX.1-2017.

129701 Most applications that use it can run when it is not present, although with a degraded level
129702 of user convenience.

129703 _POSIX_MAPPED_FILES
129704 Support for memory mapped files is mandatory in POSIX.1-2017.

129705 This facility provides for the mapping of regular files into the process address space.

129706 Both this facility and the Shared Memory Objects option provide shared access to memory
129707 objects in the process address space. The *mmap*() and *munmap*() functions provide the
129708 functionality of existing practice for mapping regular files. This functionality was deemed
129709 unnecessary, if not inappropriate, for embedded systems applications and is expected to be
129710 optional in subprofiles.

129711 _POSIX_MEMLOCK
129712 The system supports the locking of the address space.

129713 This option was created to support historical systems that did not provide the feature. It
129714 should only be required if needed, but it should never be prohibited.

129715 _POSIX_MEMLOCK_RANGE
129716 The system supports the locking of specific ranges of the address space.

129717 For applications that have well-defined sections that need to be locked and others that do
129718 not, POSIX.1-2017 supports an optional set of functions to lock or unlock a range of process
129719 addresses. The following are two reasons for having a means to lock down a specific range:

129720 1. An asynchronous event handler function that must respond to external events in a
129721 deterministic manner such that page faults cannot be tolerated

129722 2. An input/output ``buffer'' area that is the target for direct-to-process I/O, and the
129723 overhead of implicit locking and unlocking for each I/O call cannot be tolerated

129724 It should only be required if needed, but it should never be prohibited.

129725 _POSIX_MEMORY_PROTECTION
129726 Support for memory protection is mandatory in POSIX.1-2017.

129727 The provision of this facility typically imposes additional hardware requirements.

129728 _POSIX_PRIORITIZED_IO
129729 The system provides prioritization for input and output operations.

129730 The use of this option may interfere with the ability of the system to optimize input and
129731 output throughput. It should only be required if needed, but it should never be prohibited.

129732 _POSIX_MESSAGE_PASSING
129733 The system supports the passing of messages between processes.

129734 This option was created to support historical systems that did not provide the feature. The
129735 functionality adds a high-performance XSI interprocess communication facility for local
129736 communication. It should only be required if needed, but it should never be prohibited.

129737 _POSIX_MONOTONIC_CLOCK
129738 The system supports the Monotonic Clock option.

129739 This option allows realtime applications to rely on a monotonically increasing clock that
129740 does not jump backwards, and whose value does not change except for the regular ticking
129741 of the clock.

129742 _POSIX_PRIORITY_SCHEDULING
129743 The system provides priority-based process scheduling.

129744 Support of this option provides predictable scheduling behavior, allowing applications to
129745 determine the order in which processes that are ready to run are granted access to a
129746 processor. It should only be required if needed, but it should never be prohibited.

129747 _POSIX_REALTIME_SIGNALS
129748 Support for realtime signals is mandatory in POSIX.1-2017.

129749 This facility provides prioritized, queued signals with associated data values.

129750 _POSIX_REGEXP
129751 Support for regular expression facilities is mandatory in POSIX.1-2017.

129752 _POSIX_SAVED_IDS
129753 Support for this feature is mandatory in POSIX.1-2017.

129754 Certain classes of applications rely on it for proper operation, and there is no alternative
129755 short of giving the application root privileges on most implementations that did not provide
129756 _POSIX_SAVED_IDS.

129757 _POSIX_SEMAPHORES
129758 Support for counting semaphores is mandatory in POSIX.1-2017.

129759 _POSIX_SHARED_MEMORY_OBJECTS
129760 The system supports the mapping of shared memory objects into the process address space.

129761 Both this option and the Memory Mapped Files option provide shared access to memory
129762 objects in the process address space. The functions defined under this option provide the
129763 functionality of existing practice for shared memory objects. This functionality was deemed
129764 appropriate for embedded systems applications and, hence, is provided under this option.
129765 It should only be required if needed, but it should never be prohibited.

129766 _POSIX_SHELL
129767 Support for the *sh* utility command line interpreter is mandatory in POSIX.1-2017.

129768 _POSIX_SPAWN
129769 The system supports the spawn option.

129770 This option provides applications with an efficient mechanism to spawn execution of a new
129771 process.

129772 _POSIX_SPINLOCKS
129773 Support for spin locks is mandatory in POSIX.1-2017.

129774 This facility provides a simple and efficient synchronization mechanism for threads
129775 executing in multi-processor systems.

129776 _POSIX_SPORADIC_SERVER
129777 The system supports the sporadic server scheduling policy.

129778 This option provides applications with a new scheduling policy for scheduling aperiodic
129779 processes or threads in hard realtime applications.

129780 _POSIX_SYNCHRONIZED_IO
129781 The system supports guaranteed file synchronization.

129782 This option was created to support historical systems that did not provide the feature.
129783 Applications that are expecting guaranteed completion of their input and output operations
129784 should require this option, rather than the File Synchronization option. It should only be
129785 required if needed, but it should never be prohibited.

129786 _POSIX_THREADS
129787 Support for multiple threads of control within a single process is mandatory in
129788 POSIX.1-2017.

129789 _POSIX_THREAD_ATTR_STACKADDR
129790 The system supports specification of the stack address for a created thread.

129791 Applications may take advantage of support of this option for performance benefits, but
129792 dependence on this feature should be minimized. This option should never be prohibited.

129793 XSI-conformant systems support this option.

129794 _POSIX_THREAD_ATTR_STACKSIZE
129795 The system supports specification of the stack size for a created thread.

129796 Applications may require this option in order to ensure proper execution, but such usage
129797 limits portability and dependence on this feature should be minimized. It should only be
129798 required if needed, but it should never be prohibited.

129799 XSI-conformant systems support this option.

129800 _POSIX_THREAD_PRIORITY_SCHEDULING
129801 The system provides priority-based thread scheduling.

129802 Support of this option provides predictable scheduling behavior, allowing applications to
129803 determine the order in which threads that are ready to run are granted access to a processor.
129804 It should only be required if needed, but it should never be prohibited.

129805 _POSIX_THREAD_PRIO_INHERIT
129806 The system provides mutual-exclusion operations with priority inheritance.

129807 Support of this option provides predictable scheduling behavior, allowing applications to
129808 determine the order in which threads that are ready to run are granted access to a processor.
129809 It should only be required if needed, but it should never be prohibited.

129810 _POSIX_THREAD_PRIO_PROTECT
129811 The system supports a priority ceiling emulation protocol for mutual-exclusion operations.

129812 Support of this option provides predictable scheduling behavior, allowing applications to
129813 determine the order in which threads that are ready to run are granted access to a processor.
129814 It should only be required if needed, but it should never be prohibited.

129815 _POSIX_THREAD_PROCESS_SHARED
129816 The system provides shared access among multiple processes to synchronization objects.

129817 This option was created to support historical systems that did not provide the feature. It
129818 should only be required if needed, but it should never be prohibited.

129819 XSI-conformant systems support this option.

129820 _POSIX_THREAD_SAFE_FUNCTIONS
129821 Support for thread-safe functions is mandatory in POSIX.1-2017.

129822 _POSIX_THREAD_SPORADIC_SERVER
129823 The system supports the thread sporadic server scheduling policy.

129824 Support for this option provides applications with a new scheduling policy for scheduling
129825 aperiodic threads in hard realtime applications.

129826 _POSIX_TIMEOUTS
129827 Support for timeouts for some blocking services is mandatory in POSIX.1-2017.

129828 _POSIX_TIMERS
129829 Support for higher resolution clocks with multiple timers per process is mandatory in
129830 POSIX.1-2017.

129831 This facility is appropriate for applications requiring higher resolution timestamps or
129832 needing to control the timing of multiple activities.

129833 _POSIX_TRACE
129834 The system supports the Trace option.

129835 This option was created to allow applications to perform tracing.

129836 _POSIX_TRACE_EVENT_FILTER
129837 The system supports the Trace Event Filter option.

129838 This option is dependent on support of the Trace option.

129839 _POSIX_TRACE_INHERIT
129840 The system supports the Trace Inherit option.

129841 This option is dependent on support of the Trace option.

129842 _POSIX_TRACE_LOG
129843 The system supports the Trace Log option.

129844 This option is dependent on support of the Trace option.

129845 _POSIX_TYPED_MEMORY_OBJECTS
129846 The system supports the Typed Memory Objects option.

129847 This option was created to allow realtime applications to access different kinds of physical
129848 memory, and allow processes in these applications to share portions of this memory.

129849 D.3.5 Configurable Limits

129850 In general, the configurable limits in the **<limits.h>** header defined in the Base Definitions
129851 volume of POSIX.1-2017 have been set to minimal values; many applications or implementations
129852 may require larger values. No profile can cite lower values.

129853 {AIO_LISTIO_MAX}
129854 The current minimum is likely to be inadequate for most applications. It is expected that
129855 this value will be increased by profiles requiring support for list input and output
129856 operations.

129857 {AIO_MAX}
129858 The current minimum is likely to be inadequate for most applications. It is expected that
129859 this value will be increased by profiles requiring support for asynchronous input and
129860 output operations.

129861 {AIO_PRIO_DELTA_MAX}
129862 The functionality associated with this limit is needed only by sophisticated applications. It
129863 is not expected that this limit would need to be increased under a general-purpose profile.

129864 {ARG_MAX}
129865 The current minimum is likely to need to be increased for profiles, particularly as larger
129866 amounts of information are passed through the environment. Many implementations are
129867 believed to support larger values.

129868 {CHILD_MAX}
129869 The current minimum is suitable only for systems where a single user is not running
129870 applications in parallel. It is significantly too low for any system also requiring windows,
129871 and if _POSIX_JOB_CONTROL is specified, it should be raised.

129872 {CLOCKRES_MIN}
129873 It is expected that profiles will require a finer granularity clock, perhaps as fine as 1 μs,
129874 represented by a value of 1 000 for this limit.

129875 {DELAYTIMER_MAX}
129876 It is believed that most implementations will provide larger values.

129877 {LINK_MAX}
129878 For most applications and usage, the current minimum is adequate. Many implementations
129879 have a much larger value, but this should not be used as a basis for raising the value unless
129880 the applications to be used require it.

129881 {LOGIN_NAME_MAX}
129882 This is not actually a limit, but an implementation parameter. No profile should impose a
129883 requirement on this value.

129884 {MAX_CANON}
129885 For most purposes, the current minimum is adequate. Unless high-speed burst serial
129886 devices are used, it should be left as is.

129887 {MAX_INPUT}
129888 See {MAX_CANON}.

129889 {MQ_OPEN_MAX}
129890 The current minimum should be adequate for most profiles.

129891 {MQ_PRIO_MAX}
129892 The current minimum corresponds to the required number of process scheduling priorities.
129893 Many realtime practitioners believe that the number of message priority levels ought to be
129894 the same as the number of execution scheduling priorities.

129895 {NAME_MAX}
129896 Many implementations now support larger values, and many applications and users
129897 assume that larger names can be used. Many existing profiles also specify a larger value.
129898 Specifying this value will reduce the number of conforming implementations, although this
129899 might not be a significant consideration over time. Values greater than 255 should not be
129900 required.

129901 {NGROUPS_MAX}
129902 The value selected will typically be 8 or larger.

129903 {OPEN_MAX}
129904 The historically common value for this has been 20. Many implementations support larger
129905 values. If applications that use larger values are anticipated, an appropriate value should be
129906 specified.

129907 {PAGESIZE}
129908 This is not actually a limit, but an implementation parameter. No profile should impose a
129909 requirement on this value.

129910 {PATH_MAX}
129911 Historically, the minimum has been either 1 024 or indefinite, depending on the
129912 implementation. Few applications actually require values larger than 256, but some users
129913 may create file hierarchies that must be accessed with longer paths. This value should only
129914 be changed if there is a clear requirement.

129915 {PIPE_BUF}
129916 The current minimum is adequate for most applications. Historically, it has been larger. If
129917 applications that write single transactions larger than this are anticipated, it should be
129918 increased. Applications that write lines of text larger than this probably do not need it
129919 increased, as the text line is delimited by a <newline>.

129920 {POSIX_VERSION}
129921 This is actually not a limit, but a standard version stamp. Generally, a profile should specify
129922 POSIX.1-2017 by a name in the normative references section, not this value.

{PTHREAD_DESTRUCTOR_ITERATIONS}
It is unlikely that applications will need larger values to avoid loss of memory resources.

{PTHREAD_KEYS_MAX}
The current value should be adequate for most profiles.

{PTHREAD_STACK_MIN}
This should not be treated as an actual limit, but as an implementation parameter. No profile should impose a requirement on this value.

{PTHREAD_THREADS_MAX}
It is believed that most implementations will provide larger values.

{RTSIG_MAX}
The current limit was chosen so that the set of POSIX.1 signal numbers can fit within a 32-bit field. It is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the ``null signal''). Support of {_POSIX_RTSIG_MAX} additional signals may push some implementations over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64 signal line.

{SEM_NSEMS_MAX}
The current value should be adequate for most profiles.

{SEM_VALUE_MAX}
The current value should be adequate for most profiles.

{SSIZE_MAX}
This limit reflects fundamental hardware characteristics (the size of an integer), and should not be specified unless it is clearly required. Extreme care should be taken to assure that any value that might be specified does not unnecessarily eliminate implementations because of accidents of hardware design.

{STREAM_MAX}
This limit is very closely related to {OPEN_MAX}. It should never be larger than {OPEN_MAX}, but could reasonably be smaller for application areas where most files are not accessed through *stdio*. Some implementations may limit {STREAM_MAX} to 20 but allow {OPEN_MAX} to be considerably larger. Such implementations should be allowed for if the applications permit.

{TIMER_MAX}
The current limit should be adequate for most profiles, but it may need to be larger for applications with a large number of asynchronous operations.

{TTY_NAME_MAX}
This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

{TZNAME_MAX}
The minimum has been historically adequate, but if longer timezone names are anticipated (particularly such values as UTC−1), this should be increased.

D.3.6 Optional Behavior

In POSIX.1-2017, there are no instances of the terms unspecified, undefined, implementation-defined, or with the verbs ``may'' or ``need not'', that the standard developers anticipate or sanction as suitable for profile or test method citation. All of these are merely warnings to conforming applications to avoid certain areas that can vary from system to system, and even over time on the same system. In many cases, these terms are used explicitly to support extensions, but profiles should not anticipate and require such extensions; future versions of this standard may do so.

Rationale (Informative)

Part E:

Subprofiling Considerations

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Appendix E

Subprofiling Considerations (Informative)

This section contains further information to satisfy the requirement that the project scope enable subprofiling of POSIX.1-2017. The approach taken is to include a general requirement in normative text regarding subprofiling and to include an informative section (here) containing a proposed set of subprofiling options.

E.1 Subprofiling Option Groups

The following Option Groups[11] are defined to support profiling. Systems claiming support to POSIX.1-2017 need not implement these options apart from the requirements stated in XBD Section 2.1.3 (on page 17). These Option Groups allow profiles to subset the System Interfaces volume of POSIX.1-2017 by collecting sets of related functions.

FD_CLR( ), *FD_ISSET*( ), *FD_SET*( ), *FD_ZERO*( ), *clearerr*( ), *close*( ), *fclose*( ), *fdopen*( ), *feof*( ), *ferror*( ), *fflush*( ), *fgetc*( ), *fgets*( ), *fileno*( ), *fopen*( ), *fprintf*( ), *fputc*( ), *fputs*( ), *fread*( ), *freopen*( ), *fscanf*( ), *fwrite*( ), *getc*( ), *getchar*( ), *gets*( ), *open*( ), *perror*( ), *poll*( ), *printf*( ), *pread*( ), *pselect*( ), *putc*( ), *putchar*( ), *puts*( ), *pwrite*( ), *read*( ), *scanf*( ), *select*( ), *setbuf*( ), *setvbuf*( ), *stderr*, *stdin*, *stdout*, *ungetc*( ), *vfprintf*( ), *vfscanf*( ), *vprintf*( ), *vscanf*( ), *write*( )

POSIX_DEVICE_IO_EXT: Extended Device Input and Output

dprintf( ), *fmemopen*( ), *open_memstream*( ), *vdprintf*( )

POSIX_DEVICE_SPECIFIC: General Terminal

cfgetispeed( ), *cfgetospeed*( ), *cfsetispeed*( ), *cfsetospeed*( ), *ctermid*( ), *isatty*( ), *tcdrain*( ), *tcflow*( ), *tcflush*( ), *tcgetattr*( ), *tcsendbreak*( ), *tcsetattr*( ), *ttyname*( )

130064 POSIX_DEVICE_SPECIFIC_R: Thread-Safe General Terminal
130065 *ttyname_r*( )

130066 POSIX_DYNAMIC_LINKING: Dynamic Linking
130067 *dlclose*( ), *dlerror*( ), *dlopen*( ), *dlsym*( )

130068 POSIX_FD_MGMT: File Descriptor Management
130069 *dup*( ), *dup2*( ), *fcntl*( ), *fgetpos*( ), *fseek*( ), *fseeko*( ), *fsetpos*( ), *ftell*( ), *ftello*( ), *ftruncate*( ), *lseek*( ),
130070 *rewind*( )

130071 POSIX_FIFO: FIFO
130072 *mkfifo*( )

130073 POSIX_FIFO_FD: FIFO File Descriptor Routines
130074 *mkfifoat*( ), *mknodat*( )

130075 POSIX_FILE_ATTRIBUTES: File Attributes
130076 *chmod*( ), *chown*( ), *fchmod*( ), *fchown*( ), *umask*( )

130077 POSIX_FILE_ATTRIBUTES_FD: File Attributes File Descriptor Routines
130078 *fchmodat*( ), *fchownat*( )

130079 POSIX_FILE_LOCKING: Thread-Safe Stdio Locking
130080 *flockfile*( ), *ftrylockfile*( ), *funlockfile*( ), *getc_unlocked*( ), *getchar_unlocked*( ), *putc_unlocked*( ),
130081 *putchar_unlocked*( )

130082 POSIX_FILE_SYSTEM: File System
130083 *access*( ), *chdir*( ), *closedir*( ), *creat*( ), *fchdir*( ), *fpathconf*( ), *fstat*( ), *fstatvfs*( ), *getcwd*( ), *link*( ),
130084 *mkdir*( ), *mkstemp*( ), *opendir*( ), *pathconf*( ), *readdir*( ), *remove*( ), *rename*( ), *rewinddir*( ), *rmdir*( ),
130085 *stat*( ), *statvfs*( ), *tmpfile*( ), *tmpnam*( ), *truncate*( ), *unlink*( ), *utime*( )

130086 POSIX_FILE_SYSTEM_EXT: File System Extensions
130087 *alphasort*( ), *dirfd*( ), *getdelim*( ), *getline*( ), *mkdtemp*( ), *scandir*( )

130088 POSIX_FILE_SYSTEM_FD: File System File Descriptor Routines
130089 *faccessat*( ), *fdopendir*( ), *fstatat*( ), *linkat*( ), *mkdirat*( ), *openat*( ), *renameat*( ), *unlinkat*( ),
130090 *utimensat*( )

130091 POSIX_FILE_SYSTEM_GLOB: File System Glob Expansion
130092 *glob*( ), *globfree*( )

130093 POSIX_FILE_SYSTEM_R: Thread-Safe File System
130094 *readdir_r*( )

130095 POSIX_I18N: Internationalization
130096 *catclose*( ), *catgets*( ), *catopen*( ), *iconv*( ), *iconv_close*( ), *iconv_open*( ), *nl_langinfo*( )

130097 POSIX_JOB_CONTROL: Job Control
130098 *setpgid*( ), *tcgetpgrp*( ), *tcsetpgrp*( ), *tcgetsid*( )

130099 POSIX_MAPPED_FILES: Memory Mapped Files
130100 *mmap*( ), *munmap*( )

130101 POSIX_MEMORY_PROTECTION: Memory Protection
130102 *mprotect*( )

130103 POSIX_MULTI_CONCURRENT_LOCALES: Multiple Concurrent Locales
130104 *duplocale*( ), *freelocale*( ), *isalnum_l*( ), *isalpha_l*( ), *isblank_l*( ), *iscntrl_l*( ), *isdigit_l*( ), *isgraph_l*( ),
